5 things to know about Amazon's new mega-warehouse on Boxwood Road in Delaware

**Brandon Holveck**

Delaware News Journal

Published 5:28 p.m. ET Sept. 21, 2021 | Updated 9:09 p.m. ET Sept. 25, 2021

When Amazon's mega-warehouse on Boxwood Road near Newport stowed its first product last week – a plush dog toy – it became the largest operational Amazon facility in the country.

Covering roughly 640,000 square feet of ground space and five stories high, the new warehouse totals 3.8 million square feet, making it more than three times the size of Amazon's Middletown fulfillment center.

"The size is huge," said Amazon manager Qadir Stevenson.

But it's not just the size that sets the Boxwood Road facility apart. The fulfillment center features all of Amazon's latest technology, including robots that move products miles every day and sensors that detect when and where a product is stowed.

Amazon invited media on a tour of the facility Tuesday afternoon. Here's what we saw.

PREVIOUS REPORTING: Amazon's largest warehouse opens soon in Delaware. Up to 1,000 workers, robots to run high-tech site.

1. How does it work?

Nothing is manufactured at the Boxwood Road facility.

Amazon sellers send products to the warehouse where they are stored and eventually packaged for delivery to customers. The game is getting products from one point to another as efficiently as possible.

The first station products are sent to once they arrive at the warehouse is "decont," or decontainer. There, employees put products into yellow totes, which are then sent to different points across the five-story building via a winding series of conveyor belts.

The totes arrive at a stowing station where an employee puts each item into a "robotics pod." The pod looks like a large shelving unit with about a dozen small compartments on each face.

The products stowed in the robotics pods range anywhere from makeup to over-the-counter medicine and LED stripe lights. It's at this point the products appear as available on Amazon.com.

At similar looking stations, employees pick items from the pods to fulfill online orders and place them in totes that are sent elsewhere to be packaged and delivered.

The company has a device called an AFE or Amazon fulfillment engine that allows multiple products to be packaged in the same box. Amazon officials did not explain the process, citing proprietary reasons.

The Boxwood Road facility sends packages to sortation centers, which sort the packages for delivery by zip code. Packages are then sent to delivery stations, which handle the "last mile" of the process to the customer's front door.

At the back of the Boxwood Road property Amazon built a second smaller building that serves as a delivery station.

2. Robots? What do the robots do?

The upper four floors are where the robots live. They look like oversized Roomba vacuum cleaners and transport roughly 40,000 robotics pods across the facility (10,000 fit on a floor).

The robots move along a series of "alleys and roads" to the 128 stations on each floor manned by human employees. The robots are sent back and forth to the employee stations by a computer system.

At the stations, employees are bound by a wall of totes and a computer screen to one side and the robotics pod – that shelving unit of various products – to the other. Each station is dedicated to one purpose. They either store products, pick products from storage for delivery or count products to maintain an accurate inventory.

When they aren't in use, the robotics pods are returned to their spots in a perfectly formed grid covering thousands of square feet of dimly lit floor space. The robotics pods are surrounded by a chain-link fence.

Amazon touts its robotics system as a win for employee safety. It also makes the operation more efficient. Employees don't spend their day walking through shelves as though they're stocking or shopping at a massive store. The would-be shelving units can hold items on all four sides, not just the one facing outward.

DELAWARE WAREHOUSES: Online shopping, highways and nearby big cities leading to a boom in warehouses in Delaware

3. Other technology and observations

The stowing stations at the facility have a vertical light filter that detects when an employee reaches their hand into the robotics pod where products are stored.

In tandem with the computer system, which directs where products are moving from and to, the system allows stowers to sort products without having to scan each one before moving them. The containers also sense the weight of the product. The light filter was not shown to media.

Most of the interior of the facility was gray with yellow accenting. With no windows, it was all subject to the white glow of the overhead LED light panels. The parts of the warehouse shown to media were quiet.

4. Working at Amazon

Amazon has hired about 500 people for the Boxwood Road facility. It expects to hire about 500 more workers before the end of the year. Officials are also aiming for the facility to be fully operational at that time.

The stowers and pickers whose work was observed by reporters work 10- or 12-hour shifts, said General Manager Will Carney.

The minimum wage for the site on a per-hour basis is \$16.25, and employees can receive a sign-on bonus of up to \$3,000. Other benefits include a 401(k) savings plan and a college tuition program.

5. Amazon has history with Delaware

Amazon opened its first fulfillment center some 24 years ago in Delaware.

Still active today, the fulfillment center off Frenchtown Road near New Castle is smaller than the size of one floor of the new Boxwood Road facility.

Amazon has at least eight facilities planned or opened in the First State, according to media reports. They include plans for a new fulfillment center at the former Blue Diamond Park on Hamburg Road near New Castle and delivery stations in Delaware City and Seaford.

ITU-T Recommendation H.264

Advanced video coding for generic audiovisual services

Summary

This Recommendation | International Standard represents an evolution of the existing video coding standards (H.261, H.262, and H.263) and it was developed in response to the growing need for higher compression of moving pictures for various applications such as videoconferencing, digital storage media, television broadcasting, Internet streaming, and communication. It is also designed to enable the use of the coded video representation in a flexible manner for a wide variety of network environments. The use of this Recommendation | International Standard allows motion video to be manipulated as a form of computer data and to be stored on various storage media, transmitted and received over existing and future networks and distributed on existing and future broadcasting channels.

The revision approved 2005-03 contains modifications of the video coding standard to add four new profiles, referred to as the High, High 10, High 4:2:2, and High 4:4:4 profiles, to improve video quality capability and to extend the range of applications addressed by the standard (for example, by including support for a greater range of picture sample precision and higher-resolution chroma formats). Additionally, a definition of new types of supplemental data has been specified to further broaden the applicability of the video coding standard. Finally, a number of corrections to errors in the published text have been included. This revision, in addition to enhancing video coding capability, will serve to maintain technical alignment with the corresponding jointly-developed ISO/IEC 14496-10 standard.

Corrigendum 1 to ITU-T Rec. H.264 corrected and updated various minor aspects to bring the ITU-T version of the text up to date relative to the April 2005 output status approved as a new edition of the corresponding jointly-developed and technically-aligned text ISO/IEC 14496-10. It additionally fixes a number of minor errors and needs for clarification and defines three previously-reserved sample aspect ratio indicators.

This edition includes the text approved 2005-03 and its Corrigendum 1 approved 2005-09.

Source

ITU-T Recommendation H.264 was approved on 1 March 2005 by ITU-T Study Group 16 (2005-2008) under the ITU-T Recommendation A.8 procedure. It includes modifications introduced by H.264 (2005) Cor.1 approved on 13 September 2005 by ITU-T Study Group 16 (2005-2008) under the ITU-T Recommendation A.8 procedure.

FOREWORD

The International Telecommunication Union (ITU) is the United Nations specialized agency in the field of telecommunications. The ITU Telecommunication Standardization Sector (ITU-T) is a permanent organ of ITU. ITU-T is responsible for studying technical, operating and tariff questions and issuing Recommendations on them with a view to standardizing telecommunications on a worldwide basis.

The World Telecommunication Standardization Assembly (WTSA), which meets every four years, establishes the topics for study by the ITU-T study groups which, in turn, produce Recommendations on these topics.

The approval of ITU-T Recommendations is covered by the procedure laid down in WTSA Resolution 1.

In some areas of information technology which fall within ITU-T's purview, the necessary standards are prepared on a collaborative basis with ISO and IEC.

NOTE

In this Recommendation, the expression "Administration" is used for conciseness to indicate both a telecommunication administration and a recognized operating agency.

Compliance with this Recommendation is voluntary. However, the Recommendation may contain certain mandatory provisions (to ensure e.g. interoperability or applicability) and compliance with the Recommendation is achieved when all of these mandatory provisions are met. The words "shall" or some other obligatory language such as "must" and the negative equivalents are used to express requirements. The use of such words does not suggest that compliance with the Recommendation is required of any party.

INTELLECTUAL PROPERTY RIGHTS

ITU draws attention to the possibility that the practice or implementation of this Recommendation may involve the use of a claimed Intellectual Property Right. ITU takes no position concerning the evidence, validity or applicability of claimed Intellectual Property Rights, whether asserted by ITU members or others outside of the Recommendation development process.

As of the date of approval of this Recommendation, ITU had received notice of intellectual property, protected by patents, which may be required to implement this Recommendation. However, implementors are cautioned that this may not represent the latest information and are therefore strongly urged to consult the TSB patent database.

8.6.1.2	Chroma transform coefficient decoding process	179
8.6.2	SP and SI slice decoding process for switching pictures	181
8.6.2.1	Luma transform coefficient decoding process	181
8.6.2.2	Chroma transform coefficient decoding process	181
8.7	<i>Deblocking filter process</i>	182
8.7.1	Filtering process for block edges	186
8.7.2	Filtering process for a set of samples across a horizontal or vertical block edge	188
8.7.2.1	Derivation process for the luma content dependent boundary filtering strength	188
8.7.2.2	Derivation process for the thresholds for each block edge	190
8.7.2.3	Filtering process for edges with bS less than 4	191

8.7.2.4	Filtering process for edges for bS equal to 4.....	193
9	Parsing process.....	194
9.1	<i>Parsing process for Exp-Golomb codes.....</i>	<i>194</i>
9.1.1	Mapping process for signed Exp-Golomb codes	195
9.1.2	Mapping process for coded block pattern	196
9.2	<i>CAVLC parsing process for transform coefficient levels.....</i>	<i>198</i>
9.2.1	Parsing process for total number of transform coefficient levels and trailing ones	199
9.2.2	Parsing process for level information	201
9.2.2.1	Parsing process for level_prefix.....	202
9.2.3	Parsing process for run information.....	203
9.2.4	Combining level and run information	206
9.3	<i>CABAC parsing process for slice data</i>	<i>206</i>
9.3.1	Initialisation process	207
9.3.1.1	Initialisation process for context variables.....	208
9.3.1.2	Initialisation process for the arithmetic decoding engine.....	218
9.3.2	Binarization process.....	219
9.3.2.1	Unary (U) binarization process	221
9.3.2.2	Truncated unary (TU) binarization process	221
9.3.2.3	Concatenated unary/ k-th order Exp-Golomb (UEGk) binarization process	222
9.3.2.4	Fixed-length (FL) binarization process.....	222
9.3.2.5	Binarization process for macroblock type and sub-macroblock type	222
9.3.2.6	Binarization process for coded block pattern.....	225
9.3.2.7	Binarization process for mb_qp_delta	225
9.3.3	Decoding process flow.....	225
9.3.3.1	Derivation process for ctxIdx.....	226
9.3.3.1.1	Assignment process of ctxIdxInc using neighbouring syntax elements	228
9.3.3.1.1.1	Derivation process of ctxIdxInc for the syntax element mb_skip_flag.....	228
9.3.3.1.1.2	Derivation process of ctxIdxInc for the syntax element mb_field_decoding_flag.....	228
9.3.3.1.1.3	Derivation process of ctxIdxInc for the syntax element mb_type.....	229
9.3.3.1.1.4	Derivation process of ctxIdxInc for the syntax element coded_block_pattern.....	229
9.3.3.1.1.5	Derivation process of ctxIdxInc for the syntax element mb_qp_delta	230
9.3.3.1.1.6	Derivation process of ctxIdxInc for the syntax elements ref_idx_l0 and ref_idx_l1.....	230
9.3.3.1.1.7	Derivation process of ctxIdxInc for the syntax elements mvd_l0 and mvd_l1	231
9.3.3.1.1.8	Derivation process of ctxIdxInc for the syntax element intra_chroma_pred_mode.....	232
9.3.3.1.1.9	Derivation process of ctxIdxInc for the syntax element coded_block_flag	233
9.3.3.1.1.10	Derivation process of ctxIdxInc for the syntax element transform_size_8x8_flag	234
9.3.3.1.2	Assignment process of ctxIdxInc using prior decoded bin values	234
9.3.3.1.3	Assignment process of ctxIdxInc for syntax elements significant_coeff_flag, last_significant_coeff_flag, and coeff_abs_level_minus1	235
9.3.3.2	Arithmetic decoding process.....	237
9.3.3.2.1	Arithmetic decoding process for a binary decision	238
9.3.3.2.1.1	State transition process.....	239
9.3.3.2.2	Renormalization process in the arithmetic decoding engine	241
9.3.3.2.3	Bypass decoding process for binary decisions	242
9.3.3.2.4	Decoding process for binary decisions before termination	242
9.3.4	Arithmetic encoding process (informative)	243
9.3.4.1	Initialisation process for the arithmetic encoding engine (informative)	243
9.3.4.2	Encoding process for a binary decision (informative)	243
9.3.4.3	Renormalization process in the arithmetic encoding engine (informative).....	244
9.3.4.4	Bypass encoding process for binary decisions (informative).....	246
9.3.4.5	Encoding process for a binary decision before termination (informative).....	246
9.3.4.6	Byte stuffing process (informative)	247
Annex A	Profiles and levels.....	249
A.1	<i>Requirements on video decoder capability</i>	<i>249</i>
A.2	<i>Profiles.....</i>	<i>249</i>
A.2.1	Baseline profile	249
A.2.2	Main profile	250
A.2.3	Extended profile.....	250
A.2.4	High profile.....	250
A.2.5	High 10 profile.....	251
A.2.6	High 4:2:2 profile.....	251
A.2.7	High 4:4:4 profile.....	252

A.3	<i>Levels</i>	252
A.3.1	Level limits common to the Baseline, Main, and Extended profiles.....	252
A.3.2	Level limits common to the High, High 10, High 4:2:2, and High 4:4:4 profiles.....	254
A.3.3	Profile-specific level limits	255
A.3.3.1	Baseline profile limits	256
A.3.3.2	Main, High, High 10, High 4:2:2, or High 4:4:4 profile limits	257
A.3.3.3	Extended Profile Limits	258
A.3.4	Effect of level limits on frame rate (informative)	259
Annex B	Byte stream format	262
B.1	<i>Byte stream NAL unit syntax and semantics</i>	262
B.1.1	Byte stream NAL unit syntax	262
B.1.2	Byte stream NAL unit semantics	262
B.2	<i>Byte stream NAL unit decoding process</i>	262
B.3	<i>Decoder byte-alignment recovery (informative)</i>	263
Annex C	Hypothetical reference decoder	264
C.1	<i>Operation of coded picture buffer (CPB)</i>	266
C.1.1	Timing of bitstream arrival	266
C.1.2	Timing of coded picture removal	267
C.2	<i>Operation of the decoded picture buffer (DPB)</i>	268
C.2.1	Decoding of gaps in frame_num and storage of "non-existing" frames.....	268
C.2.2	Picture decoding and output.....	268
C.2.3	Removal of pictures from the DPB before possible insertion of the current picture	268
C.2.4	Current decoded picture marking and storage	269
C.2.4.1	Marking and storage of a reference decoded picture into the DPB	269
C.2.4.2	Storage of a non-reference picture into the DPB	269
C.3	<i>Bitstream conformance</i>	269
C.4	<i>Decoder conformance</i>	271
C.4.1	Operation of the output order DPB	272
C.4.2	Decoding of gaps in frame_num and storage of "non-existing" pictures.....	272
C.4.3	Picture decoding	272
C.4.4	Removal of pictures from the DPB before possible insertion of the current picture	272
C.4.5	Current decoded picture marking and storage	272
C.4.5.1	Storage and marking of a reference decoded picture into the DPB	272
C.4.5.2	Storage and marking of a non-reference decoded picture into the DPB.....	273
C.4.5.3	"Bumping" process.....	273
Annex D	Supplemental enhancement information	275
D.1	<i>SEI payload syntax</i>	276
D.1.1	Buffering period SEI message syntax	277
D.1.2	Picture timing SEI message syntax	277
D.1.3	Pan-scan rectangle SEI message syntax.....	278

Table 7-18 – Sub-macroblock types in B macroblocks	94
Table 8-1 – Refined slice group map type	102
Table 8-2 – Specification of Intra4x4PredMode[luma4x4BlkIdx] and associated names	117
Table 8-3 – Specification of Intra8x8PredMode[luma8x8BlkIdx] and associated names	123
Table 8-4 – Specification of Intra16x16PredMode and associated names	130
Table 8-5 – Specification of Intra chroma prediction modes and associated names.....	132
Table 8-6 – Specification of the variable colPic	140
Table 8-7 – Specification of PicCodingStruct(X).....	140
Table 8-8 – Specification of mbAddrCol, yM, and vertMvScale	141
Table 8-9 – Assignment of prediction utilization flags.....	143
Table 8-10 – Derivation of the vertical component of the chroma vector in field coding mode	149
Table 8-11 – Differential full-sample luma locations	153
Table 8-12 – Assignment of the luma prediction sample predPartLX _L [x _L , y _L]	155
Table 8-13 – Specification of mapping of idx to c _{ij} for zig-zag and field scan.....	164
Table 8-14 – Specification of mapping of idx to c _{ij} for 8x8 zig-zag and 8x8 field scan.....	166
Table 8-15 – Specification of QP _C as a function of qP _I	167
Table 8-16 – Derivation of offset dependent threshold variables α' and β' from indexA and indexB.....	191
Table 8-17 – Value of variable t' _{C0} as a function of indexA and bS	192
Table 9-1 – Bit strings with “prefix” and “suffix” bits and assignment to codeNum ranges (informative).....	194
Table 9-2 – Exp-Golomb bit strings and codeNum in explicit form and used as ue(v) (informative).....	195
Table 9-3 – Assignment of syntax element to codeNum for signed Exp-Golomb coded syntax elements se(v).....	196
Table 9-4 – Assignment of codeNum to values of coded_block_pattern for macroblock prediction modes	196
Table 9-5 – coeff_token mapping to TotalCoeff(coeff_token) and TrailingOnes(coeff_token).....	200
Table 9-6 – Codeword table for level_prefix (informative).....	203
Table 9-7 – total_zeros tables for 4x4 blocks with TotalCoeff(coeff_token) 1 to 7	204
Table 9-8 – total_zeros tables for 4x4 blocks with TotalCoeff(coeff_token) 8 to 15	205
Table 9-9 – total_zeros tables for chroma DC 2x2 and 2x4 blocks	205
Table 9-10 – Tables for run_before	206
Table 9-11 – Association of ctxIdx and syntax elements for each slice type in the initialisation process.....	208
Table 9-12 – Values of variables m and n for ctxIdx from 0 to 10.....	209
Table 9-13 – Values of variables m and n for ctxIdx from 11 to 23.....	210

Table 9-14 – Values of variables m and n for ctxIdx from 24 to 39.....	210
Table 9-15 – Values of variables m and n for ctxIdx from 40 to 53.....	210
Table 9-16 – Values of variables m and n for ctxIdx from 54 to 59, and 399 to 401	211
Table 9-17 – Values of variables m and n for ctxIdx from 60 to 69.....	211
Table 9-18 – Values of variables m and n for ctxIdx from 70 to 104.....	212
Table 9-19 – Values of variables m and n for ctxIdx from 105 to 165.....	213
Table 9-20 – Values of variables m and n for ctxIdx from 166 to 226.....	214
Table 9-21 – Values of variables m and n for ctxIdx from 227 to 275.....	215
Table 9-22 – Values of variables m and n for ctxIdx from 277 to 337.....	216
Table 9-23 – Values of variables m and n for ctxIdx from 338 to 398.....	217
Table 9-24 – Values of variables m and n for ctxIdx from 402 to 459.....	218
Table 9-25 – Syntax elements and associated types of binarization, maxBinIdxCtx, and ctxIdxOffset.....	220
Table 9-26 – Bin string of the unary binarization (informative).....	221
Table 9-27 – Binarization for macroblock types in I slices	223
Table 9-28 – Binarization for macroblock types in P, SP, and B slices.....	224
Table 9-29 – Binarization for sub-macroblock types in P, SP, and B slices.....	225
Table 9-30 – Assignment of ctxIdxInc to binIdx for all ctxIdxOffset values except those related to the syntax elements coded_block_flag, significant_coeff_flag, last_significant_coeff_flag, and coeff_abs_level_minus1.....	227
Table 9-31 – Assignment of ctxIdxBlockCatOffset to ctxBlockCat for syntax elements coded_block_flag, significant_coeff_flag, last_significant_coeff_flag, and coeff_abs_level_minus1	228
Table 9-32 – Specification of ctxIdxInc for specific values of ctxIdxOffset and binIdx.....	235
Table 9-33 – Specification of ctxBlockCat for the different blocks	235
Table 9-34 – Mapping of scanning position to ctxIdxInc for ctxBlockCat == 5	236
Table 9-35 – Specification of rangeTabLPS depending on pStateIdx and qCodIRangeIdx	240
Table 9-36 – State transition table	241
Table A-1 – Level limits.....	254
Table A-2 – Specification of cpbBrVclFactor and cpbBrNalFactor.....	256
Table A-3 – Baseline profile level limits.....	257
Table A-4 – Main, High, High 10, High 4:2:2, or High 4:4:4 profile level limits	257
Table A-5 – Extended profile level limits.....	258

Foreword

The International Telecommunication Union (ITU) is the United Nations specialized agency in the field of telecommunications. The ITU Telecommunication Standardization Sector (ITU-T) is a permanent organ of ITU. ITU-T is responsible for studying technical, operating and tariff questions and issuing Recommendations on them with a view to standardising telecommunications on a world-wide basis. The World Telecommunication Standardization Assembly (WTSA), which meets every four years, establishes the topics for study by the ITU-T study groups that, in turn, produce Recommendations on these topics. The approval of ITU-T Recommendations is covered by the procedure laid down in WTSA Resolution 1. In some areas of information technology that fall within ITU-T's purview, the necessary standards are prepared on a collaborative basis with ISO and IEC.

ISO (the International Organization for Standardization) and IEC (the International Electrotechnical Commission) form the specialised system for world-wide standardisation. National Bodies that are members of ISO and IEC participate in the development of International Standards through technical committees established by the respective organisation to deal with particular fields of technical activity. ISO and IEC technical committees collaborate in fields of mutual interest. Other international organisations, governmental and non-governmental, in liaison with ISO and IEC, also take part in the work. In the field of information technology, ISO and IEC have established a joint technical committee, ISO/IEC JTC 1. Draft International Standards adopted by the joint technical committee are circulated to national bodies for voting. Publication as an International Standard requires approval by at least 75% of the national bodies casting a vote.

This Recommendation | International Standard was prepared jointly by ITU-T SG 16 Q.6, also known as VCEG (Video Coding Experts Group), and by ISO/IEC JTC 1/SC 29/WG 11, also known as MPEG (Moving Picture Experts Group). VCEG was formed in 1997 to maintain prior ITU-T video coding standards and develop new video coding standard(s) appropriate for a wide range of conversational and non-conversational services. MPEG was formed in 1988 to establish standards for coding of moving pictures and associated audio for various applications such as digital storage media, distribution, and communication.

In this Recommendation | International Standard Annexes A through E contain normative requirements and are an integral part of this Recommendation | International Standard.

ITU-T Recommendation H.264

Advanced video coding for generic audiovisual services

0 Introduction

This clause does not form an integral part of this Recommendation | International Standard.

0.1 Prologue

This subclause does not form an integral part of this Recommendation | International Standard.

As the costs for both processing power and memory have reduced, network support for coded video data has diversified, and advances in video coding technology have progressed, the need has arisen for an industry standard for compressed video representation with substantially increased coding efficiency and enhanced robustness to network environments. Toward these ends the ITU-T Video Coding Experts Group (VCEG) and the ISO/IEC Moving Picture Experts Group (MPEG) formed a Joint Video Team (JVT) in 2001 for development of a new Recommendation | International Standard.

0.2 Purpose

This subclause does not form an integral part of this Recommendation | International Standard.

This Recommendation | International Standard was developed in response to the growing need for higher compression of moving pictures for various applications such as videoconferencing, digital storage media, television broadcasting, internet streaming, and communication. It is also designed to enable the use of the coded video representation in a flexible manner for a wide variety of network environments. The use of this Recommendation | International Standard allows motion video to be manipulated as a form of computer data and to be stored on various storage media, transmitted and received over existing and future networks and distributed on existing and future broadcasting channels.

0.3 Applications

This subclause does not form an integral part of this Recommendation | International Standard.

This Recommendation | International Standard is designed to cover a broad range of applications for video content including but not limited to the following:

CATV	Cable TV on optical networks, copper, etc.
DBS	Direct broadcast satellite video services
DSL	Digital subscriber line video services

0.4 Publication and versions of this specification

This subclause does not form an integral part of this Recommendation | International Standard.

This specification has been jointly developed by ITU-T Video Coding Experts Group (VCEG) and the ISO/IEC Moving Picture Experts Group. It is published as technically-aligned twin text in both organizations ITU-T and ISO/IEC.

ITU-T Rec. H.264 | ISO/IEC 14496-10 version 1 refers to the first (2003) approved version of this Recommendation | International Standard.

ITU-T Rec. H.264 | ISO/IEC 14496-10 version 2 refers to the integrated text containing the corrections specified in the first technical corrigendum.

ITU-T Rec. H.264 | ISO/IEC 14496-10 version 3 refers to the integrated text containing both the first technical corrigendum (2004) and the first amendment, which is referred to as the "Fidelity range extensions".

ITU-T Rec. H.264 | ISO/IEC 14496-10 version 4 (the current specification) refers to the integrated text containing the first technical corrigendum (2004), the first amendment (the "Fidelity range extensions"), and an additional technical corrigendum (2005). In the ITU-T, the next published version after version 2 was version 4 (due to the completion of the drafting work for version 4 prior to the approval opportunity for a final version 3 text).

0.5 Profiles and levels

This subclause does not form an integral part of this Recommendation | International Standard.

This Recommendation | International Standard is designed to be generic in the sense that it serves a wide range of applications, bit rates, resolutions, qualities, and services. Applications should cover, among other things, digital storage media, television broadcasting and real-time communications. In the course of creating this Specification, various requirements from typical applications have been considered, necessary algorithmic elements have been developed, and these have been integrated into a single syntax. Hence, this Specification will facilitate video data interchange among different applications.

Considering the practicality of implementing the full syntax of this Specification, however, a limited number of subsets of the syntax are also stipulated by means of "profiles" and "levels". These and other related terms are formally defined in clause 3.

A "profile" is a subset of the entire bitstream syntax that is specified by this Recommendation | International Standard. Within the bounds imposed by the syntax of a given profile it is still possible to require a very large variation in the performance of encoders and decoders depending upon the values taken by syntax elements in the bitstream such as the specified size of the decoded pictures. In many applications, it is currently neither practical nor economic to implement a decoder capable of dealing with all hypothetical uses of the syntax within a particular profile.

In order to deal with this problem, "levels" are specified within each profile. A level is a specified set of constraints imposed on values of the syntax elements in the bitstream. These constraints may be simple limits on values. Alternatively they may take the form of constraints on arithmetic combinations of values (e.g. picture width multiplied by picture height multiplied by number of pictures decoded per second).

Coded video content conforming to this Recommendation | International Standard uses a common syntax. In order to achieve a subset of the complete syntax, flags, parameters, and other syntax elements are included in the bitstream that signal the presence or absence of syntactic elements that occur later in the bitstream.

0.6 Overview of the design characteristics

This subclause does not form an integral part of this Recommendation | International Standard.

The coded representation specified in the syntax is designed to enable a high compression capability for a desired image quality. With the exception of the transform bypass mode of operation for lossless coding in the High 4:4:4 profile and the I_PCM mode of operation in all profiles, the algorithm is typically not lossless, as the exact source sample values are typically not preserved through the encoding and decoding processes. A number of techniques may be used to achieve highly efficient compression. Encoding algorithms (not specified in this Recommendation | International Standard) may select between inter and intra coding for block-shaped regions of each picture. Inter coding uses motion vectors for block-based inter prediction to exploit temporal statistical dependencies between different pictures. Intra coding uses various spatial prediction modes to exploit spatial statistical dependencies in the source signal for a single picture. Motion vectors and intra prediction modes may be specified for a variety of block sizes in the picture. The prediction residual is then further compressed using a transform to remove spatial correlation inside the transform block before it is quantised, producing an irreversible process that typically discards less important visual information while forming a close approximation to the source samples. Finally, the motion vectors or intra prediction modes are combined with the quantised transform coefficient information and encoded using either variable length codes or arithmetic coding.

0.6.1 Predictive coding

This subclause does not form an integral part of this Recommendation | International Standard.

Because of the conflicting requirements of random access and highly efficient compression, two main coding types are specified. Intra coding is done without reference to other pictures. Intra coding may provide access points to the coded sequence where decoding can begin and continue correctly, but typically also shows only moderate compression efficiency. Inter coding (predictive or bi-predictive) is more efficient using inter prediction of each block of sample values from some previously decoded picture selected by the encoder. In contrast to some other video coding standards, pictures coded using bi-predictive inter prediction may also be used as references for inter coding of other pictures.

The application of the three coding types to pictures in a sequence is flexible, and the order of the decoding process is generally not the same as the order of the source picture capture process in the encoder or the output order from the decoder for display. The choice is left to the encoder and will depend on the requirements of the application. The decoding order is specified such that the decoding of pictures that use inter-picture prediction follows later in decoding order than other pictures that are referenced in the decoding process.

0.6.2 Coding of progressive and interlaced video

This subclause does not form an integral part of this Recommendation | International Standard.

This Recommendation | International Standard specifies a syntax and decoding process for video that originated in either progressive-scan or interlaced-scan form, which may be mixed together in the same sequence. The two fields of an interlaced frame are separated in capture time while the two fields of a progressive frame share the same capture time. Each field may be coded separately or the two fields may be coded together as a frame. Progressive frames are typically coded as a frame. For interlaced video, the encoder can choose between frame coding and field coding. Frame coding or field coding can be adaptively selected on a picture-by-picture basis and also on a more localized basis within a coded frame. Frame coding is typically preferred when the video scene contains significant detail with limited motion. Field coding typically works better when there is fast picture-to-picture motion.

0.6.3 Picture partitioning into macroblocks and smaller partitions

This subclause does not form an integral part of this Recommendation | International Standard.

As in previous video coding Recommendations and International Standards, a macroblock, consisting of a 16x16 block of luma samples and two corresponding blocks of chroma samples, is used as the basic processing unit of the video decoding process.

A macroblock can be further partitioned for inter prediction. The selection of the size of inter prediction partitions is a result of a trade-off between the coding gain provided by using motion compensation with smaller blocks and the quantity of data needed to represent the data for motion compensation. In this Recommendation | International Standard the inter prediction process can form segmentations for motion representation as small as 4x4 luma samples in size, using motion vector accuracy of one-quarter of the luma sample grid spacing displacement. The process for inter prediction of a sample block can also involve the selection of the picture to be used as the reference picture from a number of stored previously-decoded pictures. Motion vectors are encoded differentially with respect to predicted values formed from nearby encoded motion vectors.

Typically, the encoder calculates appropriate motion vectors and other data elements represented in the video data stream. This motion estimation process in the encoder and the selection of whether to use inter prediction for the representation of each region of the video content is not specified in this Recommendation | International Standard.

0.6.4 Spatial redundancy reduction

This subclause does not form an integral part of this Recommendation | International Standard.

Both source pictures and prediction residuals have high spatial redundancy. This Recommendation | International Standard is based on the use of a block-based transform method for spatial redundancy removal. After inter prediction from previously-decoded samples in other pictures or spatial-based prediction from previously-decoded samples within the current picture, the resulting prediction residual is split into 4x4 blocks. These are converted into the transform domain where they are quantised. After quantisation many of the transform coefficients are zero or have low amplitude and can thus be represented with a small amount of encoded data. The processes of transformation and quantisation in the encoder are not specified in this Recommendation | International Standard.

0.7 How to read this specification

This subclause does not form an integral part of this Recommendation | International Standard.

It is suggested that the reader starts with clause 1 (Scope) and moves on to clause 3 (Definitions). Clause 6 should be read for the geometrical relationship of the source, input, and output of the decoder. Clause 7 (Syntax and semantics) specifies the order to parse syntax elements from the bitstream. See subclauses 7.1-7.3 for syntactical order and see subclause 7.4 for semantics; i.e., the scope, restrictions, and conditions that are imposed on the syntax elements. The actual parsing for most syntax elements is specified in clause 9 (Parsing process). Finally, clause 8 (Decoding process) specifies how the syntax elements are mapped into decoded samples. Throughout reading this specification, the reader should refer to clauses 2 (Normative references), 4 (Abbreviations), and 5 (Conventions) as needed. Annexes A through E also form an integral part of this Recommendation | International Standard.

Annex A specifies seven profiles (Baseline, Main, Extended, High, High 10, High 4:2:2 and High 4:4:4), each being tailored to certain application domains, and defines the so-called levels of the profiles. Annex B specifies syntax and semantics of a byte stream format for delivery of coded video as an ordered stream of bytes. Annex C specifies the hypothetical reference decoder and its use to check bitstream and decoder conformance. Annex D specifies syntax and semantics for supplemental enhancement information message payloads. Finally, Annex E specifies syntax and semantics of the video usability information parameters of the sequence parameter set.

Throughout this specification, statements appearing with the preamble "NOTE -" are informative and are not an integral part of this Recommendation | International Standard.

1 Scope

This document specifies ITU-T Recommendation H.264 | ISO/IEC International Standard ISO/IEC 14496-10 video coding.

2 Normative references

The following Recommendations and International Standards contain provisions which, through reference in this text, constitute provisions of this Recommendation | International Standard. At the time of publication, the editions indicated were valid. All Recommendations and Standards are subject to revision, and parties to agreements based on this Recommendation | International Standard are encouraged to investigate the possibility of applying the most recent edition of the Recommendations and Standards listed below. Members of IEC and ISO maintain registers of currently valid International Standards. The Telecommunication Standardization Bureau of the ITU maintains a list of currently valid ITU-T Recommendations.

- ITU-T Recommendation T.35 (2000), *Procedure for the allocation of ITU-T defined codes for non-standard facilities*.
- ISO/IEC 11578:1996, Annex A, *Universal Unique Identifier*.
- ISO/CIE 10527:1991, *Colorimetric Observers*.

3 Definitions

For the purposes of this Recommendation | International Standard, the following definitions apply.

- 3.1 access unit:** A set of *NAL units* always containing exactly one *primary coded picture*. In addition to the *primary coded picture*, an access unit may also contain one or more *redundant coded pictures* or other *NAL units* not containing *slices* or *slice data partitions* of a *coded picture*. The decoding of an access unit always results in a *decoded picture*.
- 3.2 AC transform coefficient:** Any *transform coefficient* for which the *frequency index* in one or both dimensions is non-zero.
- 3.3 adaptive binary arithmetic decoding process:** An entropy *decoding process* that derives the values of *bins* from a *bitstream* produced by an *adaptive binary arithmetic encoding process*.
- 3.4 adaptive binary arithmetic encoding process:** An entropy *encoding process*, not normatively specified in this Recommendation | International Standard, that codes a sequence of *bins* and produces a *bitstream* that can be decoded using the *adaptive binary arithmetic decoding process*.
- 3.5 alpha blending:** A process not specified by this Recommendation | International Standard, in which an *auxiliary coded picture* is used in combination with a *primary coded picture* and with other data not specified by this Recommendation | International Standard in the *display process*. In an alpha blending process, the samples of an *auxiliary coded picture* are interpreted as indications of the degree of opacity (or, equivalently, the degrees of transparency) associated with the corresponding *luma* samples of the *primary coded picture*.

- 3.6 arbitrary slice order:** A *decoding order* of *slices* in which the *macroblock address* of the first *macroblock* of some *slice* of a *picture* may be less than the *macroblock address* of the first *macroblock* of some other preceding *slice* of the same *coded picture*.
- 3.7 auxiliary coded picture:** A *picture* that supplements the *primary coded picture* that may be used in combination with other data not specified by this Recommendation | International Standard in the *display process*. An auxiliary coded picture has the same syntactic and semantic restrictions as a monochrome *redundant coded picture*. An auxiliary coded picture must contain the same number of *macroblocks* as the *primary coded picture*. Auxiliary coded pictures have no normative effect on the *decoding process*. See also *primary coded picture* and *redundant coded picture*.
- 3.8 B slice:** A *slice* that may be decoded using *intra prediction* from decoded samples within the same *slice* or *inter prediction* from previously-decoded *reference pictures*, using at most two *motion vectors* and *reference indices* to *predict* the sample values of each *block*.
- 3.9 bin:** One bit of a *bin string*.
- 3.10 binarization:** A set of *bin strings* for all possible values of a *syntax element*.
- 3.11 binarization process:** A unique mapping process of all possible values of a *syntax element* onto a set of *bin strings*.
- 3.12 bin string:** A string of *bins*. A bin string is an intermediate binary representation of values of *syntax elements* from the *binarization* of the *syntax element*.
- 3.13 bi-predictive slice:** See *B slice*.
- 3.14 bitstream:** A sequence of bits that forms the representation of *coded pictures* and associated data forming one or more *coded video sequences*. Bitstream is a collective term used to refer either to a *NAL unit stream* or a *byte stream*.
- 3.15 block:** An MxN (M-column by N-row) array of samples, or an MxN array of *transform coefficients*.
- 3.16 bottom field:** One of two *fields* that comprise a *frame*. Each row of a *bottom field* is spatially located immediately below a corresponding row of a *top field*.
- 3.17 bottom macroblock (of a macroblock pair):** The *macroblock* within a *macroblock pair* that contains the samples in the bottom row of samples for the *macroblock pair*. For a *field macroblock pair*, the bottom macroblock represents the samples from the region of the *bottom field* of the *frame* that lie within the spatial region of the *macroblock pair*. For a *frame macroblock pair*, the bottom macroblock represents the samples of the *frame* that lie within the bottom half of the spatial region of the *macroblock pair*.
- 3.18 broken link:** A location in a *bitstream* at which it is indicated that some subsequent *pictures* in *decoding order* may contain serious visual artefacts due to unspecified operations performed in the generation of the *bitstream*.
- 3.19 byte:** A sequence of 8 bits, written and read with the most significant bit on the left and the least significant bit on the right. When represented in a sequence of data bits, the most significant bit of a byte is first.
- 3.20 byte-aligned:** A position in a *bitstream* is byte-aligned when the position is an integer multiple of 8 bits from the position of the first bit in the *bitstream*. A bit or *byte* or *syntax element* is said to be byte-aligned when the position at which it appears in a *bitstream* is byte-aligned.
- 3.21 byte stream:** An encapsulation of a *NAL unit stream* containing *start code prefixes* and *NAL units* as specified in Annex B.
- 3.22 can:** A term used to refer to behaviour that is allowed, but not necessarily required.
- 3.23 category:** A number associated with each *syntax element*. The category is used to specify the allocation of *syntax elements* to *NAL units* for *slice data partitioning*. It may also be used in a manner determined by the application to refer to classes of *syntax elements* in a manner not specified in this Recommendation | International Standard.
- 3.24 chroma:** An adjective specifying that a sample array or single sample is representing one of the two colour difference signals related to the primary colours. The symbols used for a chroma array or sample are Cb and Cr.
- NOTE – The term chroma is used rather than the term chrominance in order to avoid the implication of the use of linear light transfer characteristics that is often associated with the term chrominance.
- 3.25 coded field:** A *coded representation* of a *field*.

- 3.26 coded frame:** A *coded representation* of a *frame*.
- 3.27 coded picture:** A *coded representation* of a *picture*. A coded picture may be either a *coded field* or a *coded frame*. Coded picture is a collective term referring to a *primary coded picture* or a *redundant coded picture*, but not to both together.
- 3.28 coded picture buffer (CPB):** A first-in first-out buffer containing *access units* in *decoding order* specified in the *hypothetical reference decoder* in Annex C.
- 3.29 coded representation:** A data element as represented in its coded form.
- 3.30 coded video sequence:** A sequence of *access units* that consists, in decoding order, of an *IDR access unit* followed by zero or more non-IDR *access units* including all subsequent *access units* up to but not including any subsequent *IDR access unit*.
- 3.31 component:** An array or single sample from one of the three arrays (*luma* and two *chroma*) that make up a *field* or *frame*.
- 3.32 complementary field pair:** A collective term for a *complementary reference field pair* or a *complementary non-reference field pair*.
- 3.33 complementary non-reference field pair:** Two *non-reference fields* that are in consecutive *access units* in *decoding order* as two *coded fields* of opposite parity where the first *field* is not already a paired *field*.
- 3.34 complementary reference field pair:** Two *reference fields* that are in consecutive *access units* in *decoding order* as two *coded fields* and share the same value of the *frame_num syntax element*, where the second *field* in *decoding order* is not an *IDR picture* and does not include a *memory_management_control_operation syntax element* equal to 5.
- 3.35 context variable:** A variable specified for the *adaptive binary arithmetic decoding process* of a *bin* by an equation containing recently decoded *bins*.
- 3.36 DC transform coefficient:** A *transform coefficient* for which the *frequency index* is zero in all dimensions.
- 3.37 decoded picture:** A *decoded picture* is derived by decoding a *coded picture*. A *decoded picture* is either a *decoded frame*, or a *decoded field*. A *decoded field* is either a *decoded top field* or a *decoded bottom field*.
- 3.38 decoded picture buffer (DPB):** A buffer holding *decoded pictures* for reference, output reordering, or output delay specified for the *hypothetical reference decoder* in Annex C.
- 3.39 decoder:** An embodiment of a *decoding process*.
- 3.40 decoding order:** The order in which *syntax elements* are processed by the *decoding process*.
- 3.41 decoding process:** The process specified in this Recommendation | International Standard that reads a *bitstream* and derives *decoded pictures* from it.
- 3.42 direct prediction:** An *inter prediction* for a *block* for which no *motion vector* is decoded. Two direct prediction modes are specified that are referred to as *spatial direct prediction* and *temporal prediction mode*.
- 3.43 display process:** A process not specified in this Recommendation | International Standard having, as its input, the cropped *decoded pictures* that are the output of the *decoding process*.
- 3.44 decoder under test (DUT):** A *decoder* that is tested for conformance to this Recommendation | International Standard by operating the *hypothetical stream scheduler* to deliver a conforming *bitstream* to the *decoder* and to the *hypothetical reference decoder* and comparing the values and timing of the output of the two *decoders*.
- 3.45 emulation prevention byte:** A *byte* equal to 0x03 that may be present within a *NAL unit*. The presence of emulation prevention bytes ensures that no sequence of consecutive *byte-aligned bytes* in the *NAL unit* contains a *start code prefix*.
- 3.46 encoder:** An embodiment of an *encoding process*.
- 3.47 encoding process:** A process, not specified in this Recommendation | International Standard, that produces a *bitstream* conforming to this Recommendation | International Standard.
- 3.48 field:** An assembly of alternate rows of a *frame*. A *frame* is composed of two *fields*, a *top field* and a *bottom field*.
- 3.49 field macroblock:** A *macroblock* containing samples from a single *field*. All *macroblocks* of a *coded field* are *field macroblocks*. When *macroblock-adaptive frame/field decoding* is in use, some *macroblocks* of a *coded frame* may be *field macroblocks*.

- 3.50 field macroblock pair:** A *macroblock pair* decoded as two *field macroblocks*.
- 3.51 field scan:** A specific sequential ordering of *transform coefficients* that differs from the *zig-zag scan* by scanning columns more rapidly than rows. Field scan is used for *transform coefficients* in *field macroblocks*.
- 3.52 flag:** A variable that can take one of the two possible values 0 and 1.
- 3.53 frame:** A *frame* contains an array of *luma* samples and two corresponding arrays of *chroma* samples. A *frame* consists of two *fields*, a *top field* and a *bottom field*.
- 3.54 frame macroblock:** A *macroblock* representing samples from the two *fields* of a *coded frame*. When *macroblock-adaptive frame/field decoding* is not in use, all *macroblocks* of a *coded frame* are *frame macroblocks*. When *macroblock-adaptive frame/field decoding* is in use, some *macroblocks* of a *coded frame* may be *frame macroblocks*.
- 3.55 frame macroblock pair:** A *macroblock pair* decoded as two *frame macroblocks*.
- 3.56 frequency index:** A one-dimensional or two-dimensional index associated with a *transform coefficient* prior to an *inverse transform* part of the *decoding process*.
- 3.57 hypothetical reference decoder (HRD):** A hypothetical *decoder* model that specifies constraints on the variability of conforming *NAL unit streams* or conforming *byte streams* that an encoding process may produce.
- 3.58 hypothetical stream scheduler (HSS):** A hypothetical delivery mechanism for the timing and data flow of the input of a *bitstream* into the *hypothetical reference decoder*. The HSS is used for checking the conformance of a *bitstream* or a *decoder*.
- 3.59 I slice:** A *slice* that is not an *SI slice* that is decoded using *prediction* only from decoded samples within the same *slice*.
- 3.60 informative:** A term used to refer to content provided in this Recommendation | International Standard that is not an integral part of this Recommendation | International Standard. Informative content does not establish any mandatory requirements for conformance to this Recommendation | International Standard.
- 3.61 instantaneous decoding refresh (IDR) access unit:** An *access unit* in which the *primary coded picture* is an *IDR picture*.
- 3.62 instantaneous decoding refresh (IDR) picture:** A *coded picture* in which all *slices* are *I* or *SI slices* that causes the *decoding process* to mark all *reference pictures* as "unused for reference" immediately after decoding the *IDR picture*. After the decoding of an *IDR picture* all following *coded pictures* in *decoding order* can be decoded without *inter prediction* from any *picture* decoded prior to the *IDR picture*. The first *picture* of each *coded video sequence* is an *IDR picture*.
- 3.63 inter coding:** Coding of a *block*, *macroblock*, *slice*, or *picture* that uses *inter prediction*.
- 3.64 inter prediction:** A *prediction* derived from decoded samples of *reference pictures* other than the current decoded *picture*.
- 3.65 interpretation sample value:** A possibly-altered value corresponding to a decoded sample value of an *auxiliary coded picture* that may be generated for use in the *display process*. Interpretation sample values are not used in the *decoding process* and have no normative effect on the *decoding process*.
- 3.66 intra coding:** Coding of a *block*, *macroblock*, *slice*, or *picture* that uses *intra prediction*.
- 3.67 intra prediction:** A *prediction* derived from the decoded samples of the same decoded *slice*.
- 3.68 intra slice:** See *I slice*.
- 3.69 inverse transform:** A part of the *decoding process* by which a set of *transform coefficients* are converted into spatial-domain values, or by which a set of *transform coefficients* are converted into *DC transform coefficients*.
- 3.70 layer:** One of a set of syntactical structures in a non-branching hierarchical relationship. Higher layers contain lower layers. The coding layers are the *coded video sequence*, *picture*, *slice*, and *macroblock* layers.
- 3.71 level:** A defined set of constraints on the values that may be taken by the *syntax elements* and variables of this Recommendation | International Standard. The same set of levels is defined for all *profiles*, with most aspects of the definition of each level being in common across different *profiles*. Individual implementations may, within specified constraints, support a different level for each supported *profile*. In a different context, level is the value of a *transform coefficient* prior to *scaling*.

- 3.72 list 0 (list 1) motion vector:** A *motion vector* associated with a *reference index* pointing into *reference picture list 0 (list 1)*.
- 3.73 list 0 (list 1) prediction:** *Inter prediction* of the content of a *slice* using a *reference index* pointing into *reference picture list 0 (list 1)*.
- 3.74 luma:** An adjective specifying that a sample array or single sample is representing the monochrome signal related to the primary colours. The symbol or subscript used for luma is Y or L.
NOTE – The term luma is used rather than the term luminance in order to avoid the implication of the use of linear light transfer characteristics that is often associated with the term luminance. The symbol L is sometimes used instead of the symbol Y to avoid confusion with the symbol y as used for vertical location.
- 3.75 macroblock:** A 16x16 *block* of *luma* samples and two corresponding *blocks* of *chroma* samples. The division of a *slice* or a *macroblock pair* into macroblocks is a *partitioning*.
- 3.76 macroblock-adaptive frame/field decoding:** A *decoding process* for *coded frames* in which some *macroblocks* may be decoded as *frame macroblocks* and others may be decoded as *field macroblocks*.
- 3.77 macroblock address:** When *macroblock-adaptive frame/field decoding* is not in use, a macroblock address is the index of a macroblock in a *macroblock raster scan* of the *picture* starting with zero for the top-left *macroblock* in a *picture*. When *macroblock-adaptive frame/field decoding* is in use, the macroblock address of the *top macroblock* of a *macroblock pair* is two times the index of the *macroblock pair* in a *macroblock pair raster scan* of the *picture*, and the macroblock address of the *bottom macroblock* of a *macroblock pair* is the macroblock address of the corresponding *top macroblock* plus 1. The macroblock address of the *top macroblock* of each *macroblock pair* is an even number and the macroblock address of the *bottom macroblock* of each *macroblock pair* is an odd number.
- 3.78 macroblock location:** The two-dimensional coordinates of a *macroblock* in a *picture* denoted by (x, y). For the top left *macroblock* of the *picture* (x, y) is equal to (0, 0). x is incremented by 1 for each *macroblock* column from left to right. When *macroblock-adaptive frame/field decoding* is not in use, y is incremented by 1 for each *macroblock* row from top to bottom. When *macroblock-adaptive frame/field decoding* is in use, y is incremented by 2 for each *macroblock pair* row from top to bottom, and is incremented by an additional 1 when a macroblock is a *bottom macroblock*.
- 3.79 macroblock pair:** A pair of vertically contiguous *macroblocks* in a *frame* that is coupled for use in *macroblock-adaptive frame/field decoding*. The division of a *slice* into macroblock pairs is a *partitioning*.
- 3.80 macroblock partition:** A *block* of *luma* samples and two corresponding *blocks* of *chroma* samples resulting from a *partitioning* of a *macroblock* for *inter prediction*.
- 3.81 macroblock to slice group map:** A means of mapping *macroblocks* of a *picture* into *slice groups*. The macroblock to slice group map consists of a list of numbers, one for each coded *macroblock*, specifying the *slice group* to which each coded *macroblock* belongs.
- 3.82 map unit to slice group map:** A means of mapping *slice group map units* of a *picture* into *slice groups*. The map unit to slice group map consists of a list of numbers, one for each *slice group map unit*, specifying the *slice group* to which each coded *slice group map unit* belongs.
- 3.83 may:** A term used to refer to behaviour that is allowed, but not necessarily required. In some places where the optional nature of the described behaviour is intended to be emphasized, the phrase "may or may not" is used to provide emphasis.
- 3.84 memory management control operation:** Seven operations that control *reference picture marking*.
- 3.85 motion vector:** A two-dimensional vector used for *inter prediction* that provides an offset from the coordinates in the *decoded picture* to the coordinates in a *reference picture*.
- 3.86 must:** A term used in expressing an observation about a requirement or an implication of a requirement that is specified elsewhere in this Recommendation | International Standard. This term is used exclusively in an *informative* context.
- 3.87 NAL unit:** A syntax structure containing an indication of the type of data to follow and *bytes* containing that data in the form of an *RBSP* interspersed as necessary with *emulation prevention bytes*.
- 3.88 NAL unit stream:** A sequence of *NAL units*.
- 3.89 non-paired field:** A collective term for a *non-paired reference field* or a *non-paired non-reference field*.
- 3.90 non-paired non-reference field:** A decoded *non-reference field* that is not part of a *complementary non-reference field pair*.

- 3.91 non-paired reference field:** A decoded *reference field* that is not part of a *complementary reference field pair*.
- 3.92 non-reference field:** A *field* coded with *nal_ref_idc* equal to 0.
- 3.93 non-reference frame:** A *frame* coded with *nal_ref_idc* equal to 0.
- 3.94 non-reference picture:** A *picture* coded with *nal_ref_idc* equal to 0. A *non-reference picture* is not used for *inter prediction* of any other *pictures*.
- 3.95 note:** A term used to prefix *informative* remarks. This term is used exclusively in an *informative* context.
- 3.96 opposite parity:** The *opposite parity* of *top* is *bottom*, and vice versa.
- 3.97 output order:** The order in which the *decoded pictures* are output from the *decoded picture buffer*.
- 3.98 P slice:** A *slice* that may be decoded using *intra prediction* from decoded samples within the same *slice* or *inter prediction* from previously-decoded *reference pictures*, using at most one *motion vector* and *reference index* to *predict* the sample values of each *block*.
- 3.99 parameter:** A *syntax element* of a *sequence parameter set* or a *picture parameter set*. Parameter is also used as part of the defined term *quantisation parameter*.
- 3.100 parity:** The parity of a *field* can be *top* or *bottom*.
- 3.101 partitioning:** The division of a set into subsets such that each element of the set is in exactly one of the subsets.
- 3.102 picture:** A collective term for a *field* or a *frame*.
- 3.103 picture parameter set:** A *syntax structure* containing *syntax elements* that apply to zero or more entire *coded pictures* as determined by the *pic_parameter_set_id syntax element* found in each *slice header*.
- 3.104 picture order count:** A variable having a value that is non-decreasing with increasing *picture* position in output order relative to the previous *IDR picture* in *decoding order* or relative to the previous *picture* containing the *memory management control operation* that marks all *reference pictures* as “unused for reference”.
- 3.105 prediction:** An embodiment of the *prediction process*.
- 3.106 prediction process:** The use of a *predictor* to provide an estimate of the sample value or data element currently being decoded.
- 3.107 predictive slice:** See *P slice*.
- 3.108 predictor:** A combination of specified values or previously decoded sample values or data elements used in the *decoding process* of subsequent sample values or data elements.
- 3.109 primary coded picture:** The coded representation of a *picture* to be used by the *decoding process* for a bitstream conforming to this Recommendation | International Standard. The primary coded picture contains all *macroblocks* of the *picture*. The only *pictures* that have a normative effect on the *decoding process* are primary coded pictures. See also *redundant coded picture*.
- 3.110 profile:** A specified subset of the syntax of this Recommendation | International Standard.
- 3.111 quantisation parameter:** A variable used by the *decoding process* for *scaling* of *transform coefficient levels*.
- 3.112 random access:** The act of starting the decoding process for a *bitstream* at a point other than the beginning of the stream.
- 3.113 raster scan:** A mapping of a rectangular two-dimensional pattern to a one-dimensional pattern such that the first entries in the one-dimensional pattern are from the first top row of the two-dimensional pattern scanned from left to right, followed similarly by the second, third, etc. rows of the pattern (going down) each scanned from left to right.
- 3.114 raw byte sequence payload (RBSP):** A *syntax structure* containing an integer number of *bytes* that is encapsulated in a *NAL unit*. An RBSP is either empty or has the form of a *string of data bits* containing *syntax elements* followed by an *RBSP stop bit* and followed by zero or more subsequent bits equal to 0.
- 3.115 raw byte sequence payload (RBSP) stop bit:** A bit equal to 1 present within a *raw byte sequence payload (RBSP)* after a *string of data bits*. The location of the end of the *string of data bits* within an RBSP can be identified by searching from the end of the RBSP for the *RBSP stop bit*, which is the last non-zero bit in the RBSP.

- 3.116 recovery point:** A point in the *bitstream* at which the recovery of an exact or an approximate representation of the *decoded pictures* represented by the *bitstream* is achieved after a *random access* or *broken link*.
- 3.117 redundant coded picture:** A coded representation of a *picture* or a part of a *picture*. The content of a redundant coded picture shall not be used by the *decoding process* for a *bitstream* conforming to this Recommendation | International Standard. A *redundant coded picture* is not required to contain all *macroblocks* in the *primary coded picture*. Redundant coded pictures have no normative effect on the *decoding process*. See also *primary coded picture*.
- 3.118 reference field:** A *reference field* may be used for *inter prediction* when *P*, *SP*, and *B slices* of a *coded field* or *field macroblocks* of a *coded frame* are decoded. See also *reference picture*.
- 3.119 reference frame:** A *reference frame* may be used for *inter prediction* when *P*, *SP*, and *B slices* of a *coded frame* are decoded. See also *reference picture*.
- 3.120 reference index:** An index into a *reference picture list*.
- 3.121 reference picture:** A *picture* with *nal_ref_idc* not equal to 0. A *reference picture* contains samples that may be used for *inter prediction* in the *decoding process* of subsequent *pictures* in *decoding order*.
- 3.122 reference picture list:** A list of *reference pictures* that is used for *inter prediction* of a *P*, *B*, or *SP slice*. For the *decoding process* of a *P* or *SP slice*, there is one reference picture list. For the *decoding process* of a *B slice*, there are two reference picture lists.
- 3.123 reference picture list 0:** A *reference picture list* used for *inter prediction* of a *P*, *B*, or *SP slice*. All *inter prediction* used for *P* and *SP slices* uses reference picture list 0. Reference picture list 0 is one of two *reference picture lists* used for *inter prediction* for a *B slice*, with the other being *reference picture list 1*.
- 3.124 reference picture list 1:** A *reference picture list* used for *inter prediction* of a *B slice*. Reference picture list 1 is one of two lists of *reference picture lists* used for *inter prediction* for a *B slice*, with the other being *reference picture list 0*.
- 3.125 reference picture marking:** Specifies, in the *bitstream*, how the *decoded pictures* are marked for *inter prediction*.
- 3.126 reserved:** The term reserved, when used in the clauses specifying some values of a particular *syntax element*, are for future use by ITU-T | ISO/IEC. These values shall not be used in *bitstreams* conforming to this Recommendation | International Standard, but may be used in future extensions of this Recommendation | International Standard by ITU-T | ISO/IEC.
- 3.127 residual:** The decoded difference between a *prediction* of a sample or data element and its decoded value.
- 3.128 run:** A number of consecutive data elements represented in the decoding process. In one context, the number of zero-valued *transform coefficient levels* preceding a non-zero *transform coefficient level* in the list of *transform coefficient levels* generated by a *zig-zag scan* or a *field scan*. In other contexts, run refers to a number of *macroblocks*.
- 3.129 sample aspect ratio:** Specifies, for assisting the display process, which is not specified in this Recommendation | International Standard, the ratio between the intended horizontal distance between the columns and the intended vertical distance between the rows of the *luma* sample array in a *frame*. Sample aspect ratio is expressed as $h:v$, where h is horizontal width and v is vertical height (in arbitrary units of spatial distance).
- 3.130 scaling:** The process of multiplying *transform coefficient levels* by a factor, resulting in *transform coefficients*.
- 3.131 sequence parameter set:** A *syntax structure* containing *syntax elements* that apply to zero or more entire *coded video sequences* as determined by the content of a *seq_parameter_set_id syntax element* found in the *picture parameter set* referred to by the *pic_parameter_set_id syntax element* found in each *slice header*.
- 3.132 shall:** A term used to express mandatory requirements for conformance to this Recommendation | International Standard. When used to express a mandatory constraint on the values of *syntax elements* or on the results obtained by operation of the specified *decoding process*, it is the responsibility of the *encoder* to ensure that the constraint is fulfilled. When used in reference to operations performed by the *decoding process*, any *decoding process* that produces identical results to the *decoding process* described herein conforms to the *decoding process* requirements of this Recommendation | International Standard.
- 3.133 should:** A term used to refer to behaviour of an implementation that is encouraged to be followed under anticipated ordinary circumstances, but is not a mandatory requirement for conformance to this Recommendation | International Standard.

- 3.134 SI slice:** A *slice* that is coded using *prediction* only from decoded samples within the same *slice* and using quantisation of the *prediction* samples. An SI slice can be coded such that its decoded samples can be constructed identically to an *SP slice*.
- 3.135 skipped macroblock:** A *macroblock* for which no data is coded other than an indication that the *macroblock* is to be decoded as "skipped". This indication may be common to several *macroblocks*.
- 3.136 slice:** An integer number of *macroblocks* or *macroblock pairs* ordered consecutively in the *raster scan* within a particular *slice group*. For the *primary coded picture*, the division of each *slice group* into slices is a *partitioning*. Although a slice contains *macroblocks* or *macroblock pairs* that are consecutive in the *raster scan* within a *slice group*, these *macroblocks* or *macroblock pairs* are not necessarily consecutive in the *raster scan* within the *picture*. The addresses of the *macroblocks* are derived from the address of the first *macroblock* in a slice (as represented in the *slice header*) and the *macroblock to slice group map*.
- 3.137 slice data partitioning:** A method of *partitioning* selected *syntax elements* into *syntax structures* based on a *category* associated with each *syntax element*.
- 3.138 slice group:** A subset of the *macroblocks* or *macroblock pairs* of a *picture*. The division of the *picture* into slice groups is a *partitioning* of the *picture*. The partitioning is specified by the *macroblock to slice group map*.
- 3.139 slice group map units:** The units of the *map unit to slice group map*.
- 3.140 slice header:** A part of a coded *slice* containing the data elements pertaining to the first or all *macroblocks* represented in the *slice*.
- 3.141 source:** Term used to describe the video material or some of its attributes before encoding.
- 3.142 SP slice:** A *slice* that is coded using *inter prediction* from previously-decoded *reference pictures*, using at most one *motion vector* and *reference index* to *predict* the sample values of each *block*. An SP slice can be coded such that its decoded samples can be constructed identically to another SP slice or an *SI slice*.
- 3.143 start code prefix:** A unique sequence of three *bytes* equal to 0x000001 embedded in the *byte stream* as a prefix to each *NAL unit*. The location of a start code prefix can be used by a *decoder* to identify the beginning of a new *NAL unit* and the end of a previous *NAL unit*. Emulation of start code prefixes is prevented within *NAL units* by the inclusion of *emulation prevention bytes*.
- 3.144 string of data bits (SODB):** A sequence of some number of bits representing *syntax elements* present within a *raw byte sequence payload* prior to the *raw byte sequence payload stop bit*. Within an SODB, the left-most bit is considered to be the first and most significant bit, and the right-most bit is considered to be the last and least significant bit.
- 3.145 sub-macroblock:** One quarter of the samples of a *macroblock*, i.e., an 8x8 *luma block* and two corresponding *chroma blocks* of which one corner is located at a corner of the *macroblock*.
- 3.146 sub-macroblock partition:** A *block* of *luma* samples and two corresponding *blocks* of *chroma* samples resulting from a *partitioning* of a *sub-macroblock* for *inter prediction*.
- 3.147 switching I slice:** See *SI slice*.
- 3.148 switching P slice:** See *SP slice*.
- 3.149 syntax element:** An element of data represented in the *bitstream*.
- 3.150 syntax structure:** Zero or more *syntax elements* present together in the *bitstream* in a specified order.
- 3.151 top field:** One of two *fields* that comprise a *frame*. Each row of a *top field* is spatially located immediately above the corresponding row of the *bottom field*.
- 3.152 top macroblock (of a macroblock pair):** The *macroblock* within a *macroblock pair* that contains the samples in the top row of samples for the *macroblock pair*. For a *field macroblock pair*, the top macroblock represents the samples from the region of the *top field* of the *frame* that lie within the spatial region of the *macroblock pair*. For a *frame macroblock pair*, the top macroblock represents the samples of the *frame* that lie within the top half of the spatial region of the *macroblock pair*.
- 3.153 transform coefficient:** A scalar quantity, considered to be in a frequency domain, that is associated with a particular one-dimensional or two-dimensional *frequency index* in an *inverse transform* part of the *decoding process*.

- 3.154 transform coefficient level:** An integer quantity representing the value associated with a particular two-dimensional frequency index in the *decoding process* prior to *scaling* for computation of a *transform coefficient* value.
- 3.155 universal unique identifier (UUID):** An identifier that is unique with respect to the space of all universal unique identifiers.
- 3.156 unspecified:** The term unspecified, when used in the clauses specifying some values of a particular *syntax element*, indicates that the values have no specified meaning in this Recommendation | International Standard and will not have a specified meaning in the future as an integral part of this Recommendation | International Standard.
- 3.157 variable length coding (VLC):** A reversible procedure for entropy coding that assigns shorter bit strings to *symbols* expected to be more frequent and longer bit strings to *symbols* expected to be less frequent.
- 3.158 zig-zag scan:** A specific sequential ordering of *transform coefficient levels* from (approximately) the lowest spatial frequency to the highest. Zig-zag scan is used for *transform coefficient levels* in *frame macroblocks*.

4 Abbreviations

For the purposes of this Recommendation | International Standard, the following abbreviations apply.

CABAC	Context-based Adaptive Binary Arithmetic Coding
CAVLC	Context-based Adaptive Variable Length Coding
CBR	Constant Bit Rate
CPB	Coded Picture Buffer
DPB	Decoded Picture Buffer
DUT	Decoder under test
FIFO	First-In, First-Out
HRD	Hypothetical Reference Decoder
HSS	Hypothetical Stream Scheduler
IDR	Instantaneous Decoding Refresh
LSB	Least Significant Bit
MB	Macroblock
MBAFF	Macroblock-Adaptive Frame-Field Coding
MSB	Most Significant Bit
NAL	Network Abstraction Layer
RBSP	Raw Byte Sequence Payload
SEI	Supplemental Enhancement Information
SODB	String Of Data Bits
UUID	Universal Unique Identifier
VBR	Variable Bit Rate
VCL	Video Coding Layer
VLC	Variable Length Coding
VUI	Video Usability Information

5 Conventions

NOTE – The mathematical operators used in this Specification are similar to those used in the C programming language. However, integer division and arithmetic shift operations are specifically defined. Numbering and counting conventions generally begin from 0.

5.1 Arithmetic operators

The following arithmetic operators are defined as follows.

+	Addition
−	Subtraction (as a two-argument operator) or negation (as a unary prefix operator)
*	Multiplication
x^y	Exponentiation. Specifies x to the power of y . In other contexts, such notation is used for superscripting not intended for interpretation as exponentiation.
/	Integer division with truncation of the result toward zero. For example, $7/4$ and $-7/-4$ are truncated to 1 and $-7/4$ and $7/-4$ are truncated to -1 .
÷	Used to denote division in mathematical equations where no truncation or rounding is intended.
$\frac{x}{y}$	Used to denote division in mathematical equations where no truncation or rounding is intended.
$\sum_{i=x}^y f(i)$	The summation of $f(i)$ with i taking all integer values from x up to and including y .
$x \% y$	Modulus. Remainder of x divided by y , defined only for integers x and y with $x \geq 0$ and $y > 0$.

When order of precedence is not indicated explicitly by use of parenthesis, the following rules apply:

- multiplication and division operations are considered to take place before addition and subtraction;
- multiplication and division operations in sequence are evaluated sequentially from left to right;
- addition and subtraction operations in sequence are evaluated sequentially from left to right.

5.2 Logical operators

The following logical operators are defined as follows:

$x \ \&\& \ y$	Boolean logical "and" of x and y
$x \ \ y$	Boolean logical "or" of x and y
!	Boolean logical "not"
$x \ ? \ y : z$	If x is TRUE or not equal to 0, evaluates to the value of y ; otherwise, evaluates to the value of z

5.3 Relational operators

The following relational operators are defined as follows:

>	Greater than
>=	Greater than or equal to
<	Less than
<=	Less than or equal to
=	Equal to
!=	Not equal to

When a relational operator is applied to a syntax element or variable that has been assigned the value "na" (not applicable), the value "na" is treated as a distinct value for the syntax element or variable. The value "na" is considered not to be equal to any other value.

5.4 Bit-wise operators

The following bit-wise operators are defined as follows:

&	Bit-wise "and". When operating on integer arguments, operates on a two's complement representation of the integer value. When operating on a binary argument that contains fewer bits than another argument, the shorter argument is extended by adding more significant bits equal to 0.
---	---

	Bit-wise "or". When operating on integer arguments, operates on a two's complement representation of the integer value. When operating on a binary argument that contains fewer bits than another argument, the shorter argument is extended by adding more significant bits equal to 0.
$x \gg y$	Arithmetic right shift of a two's complement integer representation of x by y binary digits. This function is defined only for positive integer values of y . Bits shifted into the MSBs as a result of the right shift have a value equal to the MSB of x prior to the shift operation.
$x \ll y$	Arithmetic left shift of a two's complement integer representation of x by y binary digits. This function is defined only for positive integer values of y . Bits shifted into the LSBs as a result of the left shift have a value equal to 0.

5.5 Assignment operators

The following arithmetic operators are defined as follows:

=	Assignment operator.
++	Increment, i.e., $x++$ is equivalent to $x = x + 1$; when used in an array index, evaluates to the value of the variable prior to the increment operation.
--	Decrement, i.e., $x--$ is equivalent to $x = x - 1$; when used in an array index, evaluates to the value of the variable prior to the decrement operation.
+=	Increment by amount specified, i.e., $x += 3$ is equivalent to $x = x + 3$, and $x += (-3)$ is equivalent to $x = x + (-3)$.
-=	Decrement by amount specified, i.e., $x -= 3$ is equivalent to $x = x - 3$, and $x -= (-3)$ is equivalent to $x = x - (-3)$.

5.6 Range notation

The following notation is used to specify a range of values

$x = y .. z$ x takes on integer values starting from y to z inclusive, with x , y , and z being integer numbers.

5.7 Mathematical functions

The following mathematical functions are defined as follows:

$$\text{Abs}(x) = \begin{cases} x & ; \quad x \geq 0 \\ -x & ; \quad x < 0 \end{cases} \quad (5-1)$$

$$\text{Ceil}(x) \quad \text{the smallest integer greater than or equal to } x. \quad (5-2)$$

$$\text{Clip1}_Y(x) = \text{Clip3}(0, (1 \ll \text{BitDepth}_Y) - 1, x) \quad (5-3)$$

$$\text{Clip1}_C(x) = \text{Clip3}(0, (1 \ll \text{BitDepth}_C) - 1, x) \quad (5-4)$$

$$\text{Clip3}(x, y, z) = \begin{cases} x & ; \quad z < x \\ y & ; \quad z > y \\ z & ; \quad \text{otherwise} \end{cases} \quad (5-5)$$

$$\text{Floor}(x) \quad \text{the greatest integer less than or equal to } x. \quad (5-6)$$

$$\text{InverseRasterScan}(a, b, c, d, e) = \begin{cases} (a \% (d/b)) * b; & e = 0 \\ (a / (d/b)) * c; & e = 1 \end{cases} \quad (5-7)$$

Log2(x) returns the base-2 logarithm of x. (5-8)

Log10(x) returns the base-10 logarithm of x. (5-9)

Median(x, y, z) = x + y + z – Min(x, Min(y, z)) – Max(x, Max(y, z)) (5-10)

Min(x, y) = $\begin{cases} x & ; \quad x \leq y \\ y & ; \quad x > y \end{cases}$ (5-11)

Max(x, y) = $\begin{cases} x & ; \quad x \geq y \\ y & ; \quad x < y \end{cases}$ (5-12)

Round(x) = Sign(x) * Floor(Abs(x) + 0.5) (5-13)

Sign(x) = $\begin{cases} 1 & ; \quad x \geq 0 \\ -1 & ; \quad x < 0 \end{cases}$ (5-14)

Sqrt(x) = \sqrt{x} (5-15)

5.8 Variables, syntax elements, and tables

Syntax elements in the bitstream are represented in **bold** type. Each syntax element is described by its name (all lower case letters with underscore characters), its one or two syntax categories, and one or two descriptors for its method of coded representation. The decoding process behaves according to the value of the syntax element and to the values of previously decoded syntax elements. When a value of a syntax element is used in the syntax tables or the text, it appears in regular (i.e., not bold) type.

In some cases the syntax tables may use the values of other variables derived from syntax elements values. Such variables appear in the syntax tables, or text, named by a mixture of lower case and upper case letter and without any underscore characters. Variables starting with an upper case letter are derived for the decoding of the current syntax structure and all depending syntax structures. Variables starting with an upper case letter may be used in the decoding process for later syntax structures mentioning the originating syntax structure of the variable. Variables starting with a lower case letter are only used within the subclause in which they are derived.

In some cases, "mnemonic" names for syntax element values or variable values are used interchangeably with their numerical values. Sometimes "mnemonic" names are used without any associated numerical values. The association of values and names is specified in the text. The names are constructed from one or more groups of letters separated by an underscore character. Each group starts with an upper case letter and may contain more upper case letters.

NOTE – The syntax is described in a manner that closely follows the C-language syntactic constructs.

Functions are described by their names, which are constructed as syntax element names, with left and right round parentheses including zero or more variable names (for definition) or values (for usage), separated by commas (if more than one variable).

A one-dimensional array is referred to as a list. A two-dimensional array is referred to as a matrix. Arrays can either be syntax elements or variables. Subscripts or square parentheses are used for the indexing of arrays. In reference to a visual depiction of a matrix, the first subscript is used as a row (vertical) index and the second subscript is used as a column (horizontal) index. The indexing order is reversed when using square parentheses rather than subscripts for indexing. Thus, an element of a matrix s at horizontal position x and vertical position y may be denoted either as s[x, y] or as s_{yx}.

Binary notation is indicated by enclosing the string of bit values by single quote marks. For example, '01000001' represents an eight-bit string having only its second and its last bits equal to 1.

Hexadecimal notation, indicated by prefixing the hexadecimal number by "0x", may be used instead of binary notation when the number of bits is an integer multiple of 4. For example, 0x41 represents an eight-bit string having only its second and its last bits equal to 1.

Numerical values not enclosed in single quotes and not prefixed by "0x" are decimal values.

A value equal to 0 represents a FALSE condition in a test statement. The value TRUE is represented by any other value different than zero.

5.9 Text description of logical operations

In the text, a statement of logical operations as would be described in pseudo-code as

```
if( condition 0 )
    statement 0
else if ( condition 1 )
    statement 1
...
else /* informative remark on remaining condition */
    statement n
```

may be described in the following manner:

... as follows / ... the following applies.

- If condition 0, statement 0
- Otherwise, if condition 1, statement 1
- ...
- Otherwise (informative remark on remaining condition), statement n

Each "If...Otherwise, if...Otherwise, ..." statement in the text is introduced with "... as follows" or "... the following applies" immediately followed by "If ... ". The last condition of the "If...Otherwise, if...Otherwise, ..." is always an "Otherwise, ...". Interleaved "If...Otherwise, if...Otherwise, ..." statements can be identified by matching "... as follows" or "... the following applies" with the ending "Otherwise, ...".

In the text, a statement of logical operations as would be described in pseudo-code as

```
if( condition 0a && condition 0b )
    statement 0
else if ( condition 1a || condition 1b )
    statement 1
...
else
    statement n
```

may be described in the following manner:

... as follows / ... the following applies.

- If all of the following conditions are true, statement 0
 - condition 0a
 - condition 0b
- Otherwise, if any of the following conditions are true, statement 1
 - condition 1a
 - condition 1b
- ...
- Otherwise, statement n

In the text, a statement of logical operations as would be described in pseudo-code as

```
if( condition 0 )
    statement 0
if ( condition 1 )
    statement 1
```

may be described in the following manner:

```
When condition 0, statement 0
When condition 1, statement 1
```

5.10 Processes

Processes are used to describe the decoding of syntax elements. A process has a separate specification and invoking. All syntax elements and upper case variables that pertain to the current syntax structure and depending syntax structures are available in the process specification and invoking. A process specification may also have a lower case variable explicitly specified as the input. Each process specification has explicitly specified an output. The output is a variable that can either be an upper case variable or a lower case variable.

The assignment of variables is specified as follows.

- If invoking a process, variables are explicitly assigned to lower case input or output variables of the process specification in case these do not have the same name.
- Otherwise (when the variables at the invoking and specification have the same name), assignment is implied.

In the specification of a process, a specific macroblock may be referred to by the variable name having a value equal to the address of the specific macroblock.

6 Source, coded, decoded and output data formats, scanning processes, and neighbouring relationships

6.1 Bitstream formats

This subclause specifies the relationship between the NAL unit stream and byte stream, either of which are referred to as the bitstream.

The bitstream can be in one of two formats: the NAL unit stream format or the byte stream format. The NAL unit stream format is conceptually the more "basic" type. It consists of a sequence of syntax structures called NAL units. This sequence is ordered in decoding order. There are constraints imposed on the decoding order (and contents) of the NAL units in the NAL unit stream.

The byte stream format can be constructed from the NAL unit stream format by ordering the NAL units in decoding order and prefixing each NAL unit with a start code prefix and zero or more zero-valued bytes to form a stream of bytes. The NAL unit stream format can be extracted from the byte stream format by searching for the location of the unique start code prefix pattern within this stream of bytes. Methods of framing the NAL units in a manner other than use of the byte stream format are outside the scope of this Recommendation | International Standard. The byte stream format is specified in Annex B.

6.2 Source, decoded, and output picture formats

This subclause specifies the relationship between source and decoded frames and fields that is given via the bitstream.

The video source that is represented by the bitstream is a sequence of either or both frames or fields (called collectively pictures) in decoding order.

The source and decoded pictures (frames or fields) are each comprised of one or more sample arrays:

- Luma (Y) only (monochrome), with or without an auxiliary array.
- Luma and two Chroma (YCbCr or YCgCo), with or without an auxiliary array.
- Green, Blue and Red (GBR, also known as RGB), with or without an auxiliary array.

- Arrays representing other unspecified monochrome or tri-stimulus colour samplings (for example, YZX, also known as XYZ), with or without an auxiliary array.

For convenience of notation and terminology in this specification, the variables and terms associated with these arrays are referred to as luma (or L or Y) and chroma, where the two chroma arrays are referred to as Cb and Cr; regardless of the actual colour representation method in use. The actual colour representation method in use can be indicated in syntax that is specified in Annex E. The (monochrome) auxiliary arrays, which may or may not be present as auxiliary pictures in a coded video sequence, are optional for decoding and can be used for such purposes as alpha blending.

The variables SubWidthC, and SubHeightC are specified in Table 6-1, depending on the chroma format sampling structure, which is specified through chroma_format_idc. An entry marked as "-" in Table 6-1 denotes an undefined value for SubWidthC or SubHeightC. Other values of chroma_format_idc, SubWidthC, and SubHeightC may be specified in the future by ITU-T | ISO/IEC.

Table 6-1 – SubWidthC, and SubHeightC values derived from chroma_format_idc

chroma_format_idc	Chroma Format	SubWidthC	SubHeightC
0	monochrome	–	–
1	4:2:0	2	2
2	4:2:2	2	1
3	4:4:4	1	1

In monochrome sampling there is only one sample array, which is nominally considered the luma array.

In 4:2:0 sampling, each of the two chroma arrays has half the height and half the width of the luma array.

In 4:2:2 sampling, each of the two chroma arrays has the same height and half the width of the luma array.

In 4:4:4 sampling, each of the two chroma arrays has the same height and width as the luma array.

The width and height of the luma sample arrays are each an integer multiple of 16. In bitstreams using 4:2:0 chroma sampling, the width and height of chroma sample arrays are each an integer multiple of 8. In bitstreams using 4:2:2 sampling, the width of the chroma sample arrays is an integer multiple of 8 and the height is an integer multiple of 16. The height of a luma array that is coded as two separate fields or in macroblock-adaptive frame-field coding (see below) is an integer multiple of 32. In bitstreams using 4:2:0 chroma sampling, the height of each chroma array that is coded as two separate fields or in macroblock-adaptive frame-field coding (see below) is an integer multiple of 16. The width or height of pictures output from the decoding process need not be an integer multiple of 16 and can be specified using a cropping rectangle.

The syntax for the luma and (when present) chroma arrays are ordered such when data for all three colour components is present, the data for the luma array is first, followed by any data for the Cb array, followed by any data for the Cr array, unless otherwise specified.

The width of fields coded referring to a specific sequence parameter set is the same as that of frames coded referring to the same sequence parameter set (see below). The height of fields coded referring to a specific sequence parameter set is half that of frames coded referring to the same sequence parameter set (see below).

The number of bits necessary for the representation of each of the samples in the luma and chroma arrays in a video sequence is in the range of 8 to 12, and the number of bits used in the luma array may differ from the number of bits used in the chroma arrays.

When the value of chroma_format_idc is equal to 1, the nominal vertical and horizontal relative locations of luma and chroma samples in frames are shown in Figure 6-1. Alternative chroma sample relative locations may be indicated in video usability information (see Annex E).

Figure 6-1 – Nominal vertical and horizontal locations of 4:2:0 luma and chroma samples in a frame

A frame consists of two fields as described below. A coded picture may represent a coded frame or an individual coded field. A coded video sequence conforming to this Recommendation | International Standard may contain arbitrary combinations of coded frames and coded fields. The decoding process is also specified in a manner that allows smaller regions of a coded frame to be coded either as a frame or field region, by use of macroblock-adaptive frame-field coding.

Source and decoded fields are one of two types: top field or bottom field. When two fields are output at the same time, or are combined to be used as a reference frame (see below), the two fields (which shall be of opposite parity) are interleaved. The first (i.e., top), third, fifth, etc. rows of a decoded frame are the top field rows. The second, fourth, sixth, etc. rows of a decoded frame are the bottom field rows. A top field consists of only the top field rows of a decoded frame. When the top field or bottom field of a decoded frame is used as a reference field (see below) only the even rows (for a top field) or the odd rows (for a bottom field) of the decoded frame are used.

When the value of `chroma_format_idc` is equal to 1, the nominal vertical and horizontal relative locations of luma and chroma samples in top and bottom fields are shown in Figure 6-2. The nominal vertical sampling relative locations of the chroma samples in a top field are specified as shifted up by one-quarter luma sample height relative to the field-sampling grid. The vertical sampling locations of the chroma samples in a bottom field are specified as shifted down by one-quarter luma sample height relative to the field-sampling grid. Alternative chroma sample relative locations may be indicated in the video usability information (see Annex E).

NOTE – The shifting of the chroma samples is in order for these samples to align vertically to the usual location relative to the full-frame sampling grid as shown in Figure 6-1.

Figure 6-2 – Nominal vertical and horizontal sampling locations of 4:2:0 samples in top and bottom fields

When the value of `chroma_format_idc` is equal to 2, the chroma samples are co-sited with the corresponding luma samples and the nominal locations in a frame and in fields are as shown in Figure 6-3 – Nominal vertical and horizontal locations of 4:2:2 luma and chroma samples in a frame and Figure 6-4, respectively.

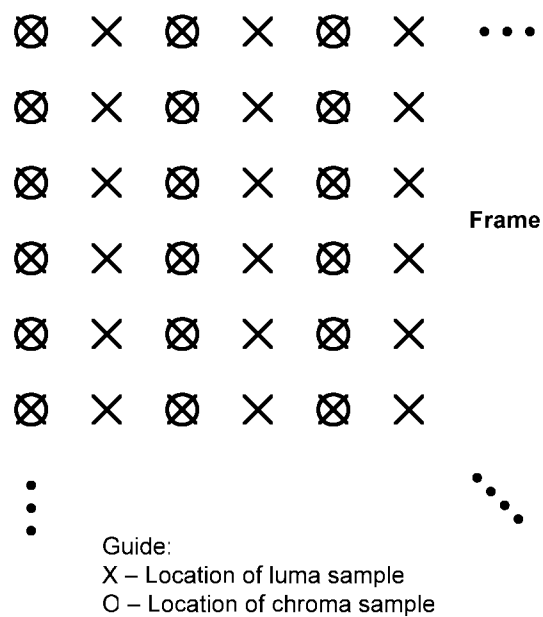

Figure 6-3 – Nominal vertical and horizontal locations of 4:2:2 luma and chroma samples in a frame

Figure 6-4 – Nominal vertical and horizontal sampling locations of 4:2:2 samples top and bottom fields

When the value of chroma_format_idc is equal to 3, all array samples are co-sited for all cases of frames and fields and the nominal locations in a frame and in fields are as shown in Figures 6-5 and 6-6, respectively.

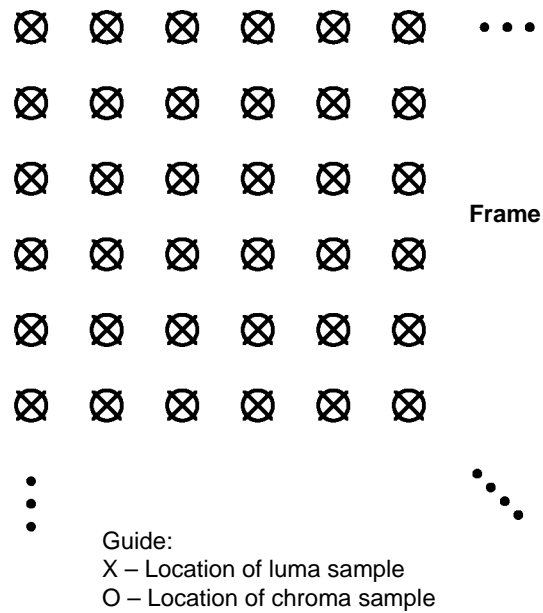

Figure 6-5 – Nominal vertical and horizontal locations of 4:4:4 luma and chroma samples in a frame

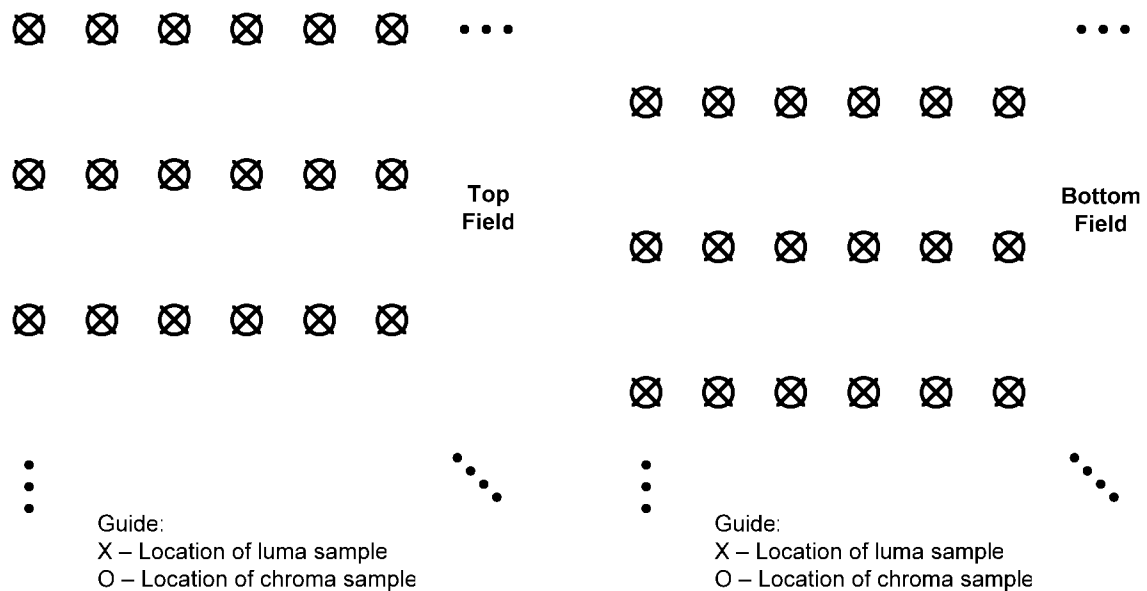

Figure 6-6 – Nominal vertical and horizontal sampling locations of 4:4:4 samples top and bottom fields

The samples are processed in units of macroblocks. The luma array for each macroblock is 16 samples in both width and height. The variables MbWidthC and MbHeightC, which specify the width and height, respectively, of the chroma arrays for each macroblock, are derived as follows.

- If chroma_format_idc is equal to 0 (monochrome), MbWidthC and MbHeightC are both equal to 0 (as no chroma arrays are specified for monochrome video).
- Otherwise, MbWidthC and MbHeightC are derived as

$$\text{MbWidthC} = 16 / \text{SubWidthC} \quad (6-1)$$

$$\text{MbHeightC} = 16 / \text{SubHeightC} \quad (6-2)$$

6.3 Spatial subdivision of pictures and slices

This subclause specifies how a picture is partitioned into slices and macroblocks. Pictures are divided into slices. A slice is a sequence of macroblocks, or, when macroblock-adaptive frame/field decoding is in use, a sequence of macroblock pairs.

Each macroblock is comprised of one 16x16 luma array and, when the video format is not monochrome, two corresponding chroma sample arrays. When macroblock-adaptive frame/field decoding is not in use, each macroblock represents a spatial rectangular region of the picture. For example, a picture may be divided into two slices as shown in Figure 6-7.

Figure 6-7 – A picture with 11 by 9 macroblocks that is partitioned into two slices

When macroblock-adaptive frame/field decoding is in use, the picture is partitioned into slices containing an integer number of macroblock pairs as shown in Figure 6-8. Each macroblock pair consists of two macroblocks.

Figure 6-8 – Partitioning of the decoded frame into macroblock pairs

6.4 Inverse scanning processes and derivation processes for neighbours

This subclause specifies inverse scanning processes; i.e., the mapping of indices to locations, and derivation processes for neighbours.

6.4.1 Inverse macroblock scanning process

Input to this process is a macroblock address mbAddr.

Output of this process is the location (x, y) of the upper-left luma sample for the macroblock with address mbAddr relative to the upper-left sample of the picture.

The inverse macroblock scanning process is specified as follows.

- If MbaffFrameFlag is equal to 0,

$$x = \text{InverseRasterScan}(\text{mbAddr}, 16, 16, \text{PicWidthInSamples}_L, 0) \quad (6-3)$$

$$y = \text{InverseRasterScan}(\text{mbAddr}, 16, 16, \text{PicWidthInSamples}_L, 1) \quad (6-4)$$

- Otherwise (MbaffFrameFlag is equal to 1), the following applies.

$$xO = \text{InverseRasterScan}(\text{mbAddr} / 2, 16, 32, \text{PicWidthInSamples}_L, 0) \quad (6-5)$$

$$yO = \text{InverseRasterScan}(\text{mbAddr} / 2, 16, 32, \text{PicWidthInSamples}_L, 1) \quad (6-6)$$

Depending on the current macroblock the following applies.

- If the current macroblock is a frame macroblock

$$x = xO \quad (6-7)$$

$$y = yO + (\text{mbAddr} \% 2) * 16 \quad (6-8)$$

- Otherwise (the current macroblock is a field macroblock),

$$x = xO \quad (6-9)$$

$$y = yO + (\text{mbAddr} \% 2) \quad (6-10)$$

6.4.2 Inverse macroblock partition and sub-macroblock partition scanning process

Macroblocks or sub-macroblocks may be partitioned, and the partitions are scanned for inter prediction as shown in Figure 6-9. The outer rectangles refer to the samples in a macroblock or sub-macroblock, respectively. The rectangles refer to the partitions. The number in each rectangle specifies the index of the inverse macroblock partition scan or inverse sub-macroblock partition scan.

The functions MbPartWidth(), MbPartHeight(), SubMbPartWidth(), and SubMbPartHeight() describing the width and height of macroblock partitions and sub-macroblock partitions are specified in Tables 7-13, 7-14, 7-17, and 7-18. MbPartWidth() and MbPartHeight() are set to appropriate values for each macroblock, depending on the macroblock type. SubMbPartWidth() and SubMbPartHeight() are set to appropriate values for each sub-macroblock of a macroblock with mb_type equal to P_8x8, P_8x8ref0, or B_8x8, depending on the sub-macroblock type.

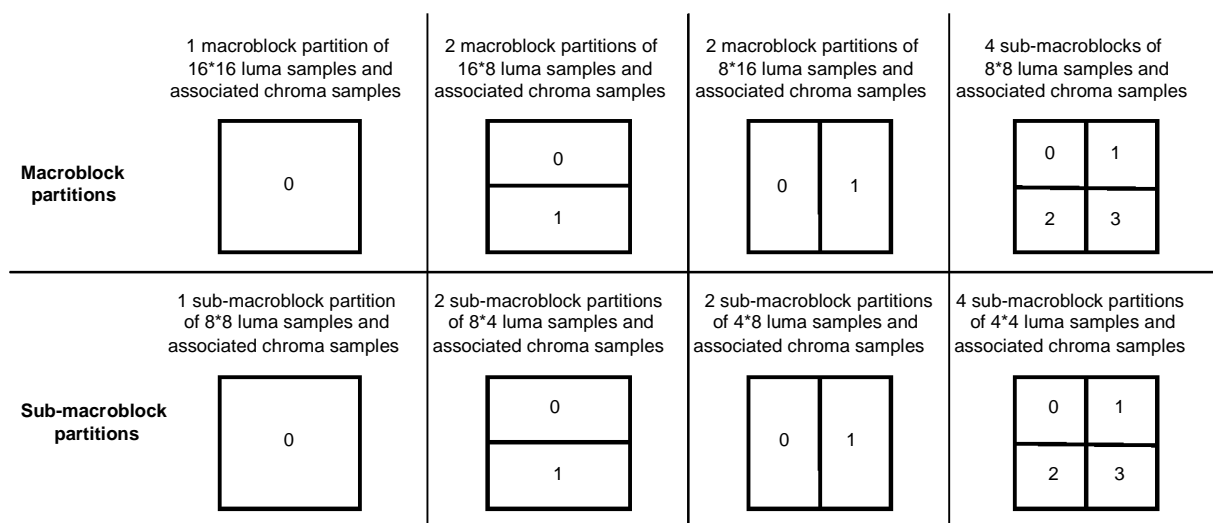

Figure 6-9 – Macroblock partitions, sub-macroblock partitions, macroblock partition scans, and sub-macroblock partition scans

6.4.2.1 Inverse macroblock partition scanning process

Input to this process is the index of a macroblock partition $mbPartIdx$.

Output of this process is the location (x, y) of the upper-left luma sample for the macroblock partition $mbPartIdx$ relative to the upper-left sample of the macroblock.

The inverse macroblock partition scanning process is specified by

$$x = \text{InverseRasterScan}(mbPartIdx, MbPartWidth(mb_type), MbPartHeight(mb_type), 16, 0) \quad (6-11)$$

$$y = \text{InverseRasterScan}(mbPartIdx, MbPartWidth(mb_type), MbPartHeight(mb_type), 16, 1) \quad (6-12)$$

6.4.2.2 Inverse sub-macroblock partition scanning process

Inputs to this process are the index of a macroblock partition $mbPartIdx$ and the index of a sub-macroblock partition $subMbPartIdx$.

Output of this process is the location (x, y) of the upper-left luma sample for the sub-macroblock partition $subMbPartIdx$ relative to the upper-left sample of the sub-macroblock.

The inverse sub-macroblock partition scanning process is specified as follows.

- If mb_type is equal to P_8x8, P_8x8ref0, or B_8x8,

$$x = \text{InverseRasterScan}(subMbPartIdx, \text{SubMbPartWidth}(sub_mb_type[mbPartIdx]), \text{SubMbPartHeight}(sub_mb_type[mbPartIdx]), 8, 0) \quad (6-13)$$

$$y = \text{InverseRasterScan}(subMbPartIdx, \text{SubMbPartWidth}(sub_mb_type[mbPartIdx]), \text{SubMbPartHeight}(sub_mb_type[mbPartIdx]), 8, 1) \quad (6-14)$$

- Otherwise,

$$x = \text{InverseRasterScan}(subMbPartIdx, 4, 4, 8, 0) \quad (6-15)$$

$$y = \text{InverseRasterScan}(subMbPartIdx, 4, 4, 8, 1) \quad (6-16)$$

6.4.3 Inverse 4x4 luma block scanning process

Input to this process is the index of a 4x4 luma block luma4x4BlkIdx.

Output of this process is the location (x, y) of the upper-left luma sample for the 4x4 luma block with index luma4x4BlkIdx relative to the upper-left luma sample of the macroblock.

Figure 6-10 shows the scan for the 4x4 luma blocks.

0	1	4	5
2	3	6	7
8	9	12	13
10	11	14	15

Figure 6-10 – Scan for 4x4 luma blocks

The inverse 4x4 luma block scanning process is specified by

$$x = \text{InverseRasterScan}(\text{luma4x4BlkIdx} / 4, 8, 8, 16, 0) + \text{InverseRasterScan}(\text{luma4x4BlkIdx} \% 4, 4, 4, 8, 0) \quad (6-17)$$

$$y = \text{InverseRasterScan}(\text{luma4x4BlkIdx} / 4, 8, 8, 16, 1) + \text{InverseRasterScan}(\text{luma4x4BlkIdx} \% 4, 4, 4, 8, 1) \quad (6-18)$$

6.4.4 Inverse 8x8 luma block scanning process

Input to this process is the index of an 8x8 luma block luma8x8BlkIdx.

Output of this process is the location (x, y) of the upper-left luma sample for the 8x8 luma block with index luma8x8BlkIdx relative to the upper-left luma sample of the macroblock.

Figure 6-11 shows the scan for the 8x8 luma blocks.

0	1
2	3

Figure 6-11 – Scan for 8x8 luma blocks

The inverse 8x8 luma block scanning process is specified by

$$x = \text{InverseRasterScan}(\text{luma8x8BlkIdx}, 8, 8, 16, 0) \quad (6-19)$$

$$y = \text{InverseRasterScan}(\text{luma8x8BlkIdx}, 8, 8, 16, 1) \quad (6-20)$$

6.4.5 Derivation process of the availability for macroblock addresses

Input to this process is a macroblock address mbAddr.

Output of this process is the availability of the macroblock mbAddr.

NOTE – The meaning of availability is determined when this process is invoked.

The macroblock is marked as available, unless one of the following conditions is true in which case the macroblock is marked as not available:

- $mbAddr < 0$
- $mbAddr > CurrMbAddr$
- the macroblock with address $mbAddr$ belongs to a different slice than the macroblock with address $CurrMbAddr$

6.4.6 Derivation process for neighbouring macroblock addresses and their availability

This process can only be invoked when $MbaffFrameFlag$ is equal to 0.

The outputs of this process are

- $mbAddrA$: the address and availability status of the macroblock to the left of the current macroblock.
- $mbAddrB$: the address and availability status of the macroblock above the current macroblock.
- $mbAddrC$: the address and availability status of the macroblock above-right of the current macroblock.
- $mbAddrD$: the address and availability status of the macroblock above-left of the current macroblock.

Figure 6-12 shows the relative spatial locations of the macroblocks with $mbAddrA$, $mbAddrB$, $mbAddrC$, and $mbAddrD$ relative to the current macroblock with $CurrMbAddr$.

$mbAddrD$	$mbAddrB$	$mbAddrC$
$mbAddrA$	$CurrMbAddr$	

Figure 6-12 – Neighbouring macroblocks for a given macroblock

Input to the process in subclause 6.4.5 is $mbAddrA = CurrMbAddr - 1$ and the output is whether the macroblock $mbAddrA$ is available. In addition, $mbAddrA$ is marked as not available when $CurrMbAddr \% PicWidthInMbs$ is equal to 0.

Input to the process in subclause 6.4.5 is $mbAddrB = CurrMbAddr - PicWidthInMbs$ and the output is whether the macroblock $mbAddrB$ is available.

Input to the process in subclause 6.4.5 is $mbAddrC = CurrMbAddr - PicWidthInMbs + 1$ and the output is whether the macroblock $mbAddrC$ is available. In addition, $mbAddrC$ is marked as not available when $(CurrMbAddr + 1) \% PicWidthInMbs$ is equal to 0.

Input to the process in subclause 6.4.5 is $mbAddrD = CurrMbAddr - PicWidthInMbs - 1$ and the output is whether the macroblock $mbAddrD$ is available. In addition, $mbAddrD$ is marked as not available when $CurrMbAddr \% PicWidthInMbs$ is equal to 0.

6.4.7 Derivation process for neighbouring macroblock addresses and their availability in MBAFF frames

This process can only be invoked when $MbaffFrameFlag$ is equal to 1.

The outputs of this process are

- $mbAddrA$: the address and availability status of the top macroblock of the macroblock pair to the left of the current macroblock pair.
- $mbAddrB$: the address and availability status of the top macroblock of the macroblock pair above the current macroblock pair.

- mbAddrC: the address and availability status of the top macroblock of the macroblock pair above-right of the current macroblock pair.
- mbAddrD: the address and availability status of the top macroblock of the macroblock pair above-left of the current macroblock pair.

Figure 6-13 shows the relative spatial locations of the macroblocks with mbAddrA, mbAddrB, mbAddrC, and mbAddrD relative to the current macroblock with CurrMbAddr.

mbAddrA, mbAddrB, mbAddrC, and mbAddrD have identical values regardless whether the current macroblock is the top or the bottom macroblock of a macroblock pair.

mbAddrD	mbAddrB	mbAddrC
mbAddrA	CurrMbAddr or CurrMbAddr	

Figure 6-13 – Neighbouring macroblocks for a given macroblock in MBAFF frames

Input to the process in subclause 6.4.5 is $mbAddrA = 2 * (CurrMbAddr / 2 - 1)$ and the output is whether the macroblock mbAddrA is available. In addition, mbAddrA is marked as not available when $(CurrMbAddr / 2) \% PicWidthInMbs$ is equal to 0.

Input to the process in subclause 6.4.5 is $mbAddrB = 2 * (CurrMbAddr / 2 - PicWidthInMbs)$ and the output is whether the macroblock mbAddrB is available.

Input to the process in subclause 6.4.5 is $mbAddrC = 2 * (CurrMbAddr / 2 - PicWidthInMbs + 1)$ and the output is whether the macroblock mbAddrC is available. In addition, mbAddrC is marked as not available when $(CurrMbAddr / 2 + 1) \% PicWidthInMbs$ is equal to 0.

Input to the process in subclause 6.4.5 is $mbAddrD = 2 * (CurrMbAddr / 2 - PicWidthInMbs - 1)$ and the output is whether the macroblock mbAddrD is available. In addition, mbAddrD is marked as not available when $(CurrMbAddr / 2) \% PicWidthInMbs$ is equal to 0.

6.4.8 Derivation processes for neighbouring macroblocks, blocks, and partitions

Subclause 6.4.8.1 specifies the derivation process for neighbouring macroblocks.

Subclause 6.4.8.2 specifies the derivation process for neighbouring 8x8 luma blocks.

Subclause 6.4.8.3 specifies the derivation process for neighbouring 4x4 luma blocks.

Subclause 6.4.8.4 specifies the derivation process for neighbouring 4x4 chroma blocks.

Subclause 6.4.8.5 specifies the derivation process for neighbouring partitions.

Table 6-2 specifies the values for the difference of luma location (xD, yD) for the input and the replacement for N in mbAddrN, mbPartIdxN, subMbPartIdxN, luma8x8BlkIdxN, luma4x4BlkIdxN, and chroma4x4BlkIdxN for the output. These input and output assignments are used in subclauses 6.4.8.1 to 6.4.8.5. The variable predPartWidth is specified when Table 6-2 is referred to.

Table 6-2 – Specification of input and output assignments for subclauses 6.4.8.1 to 6.4.8.5

N	xD	yD
A	-1	0
B	0	-1
C	predPartWidth	-1
D	-1	-1

Figure 6-14 illustrates the relative location of the neighbouring macroblocks, blocks, or partitions A, B, C, and D to the current macroblock, partition, or block, when the current macroblock, partition, or block is in frame coding mode.

Figure 6-14 – Determination of the neighbouring macroblock, blocks, and partitions (informative)

6.4.8.1 Derivation process for neighbouring macroblocks

Outputs of this process are

- mbAddrA: the address of the macroblock to the left of the current macroblock and its availability status and
- mbAddrB: the address of the macroblock above the current macroblock and its availability status.
- mbAddrN (with N being A or B) is derived as follows.
- The difference of luma location (xD, yD) is set according to Table 6-2.
- The derivation process for neighbouring locations as specified in subclause 6.4.9 is invoked for luma locations with (xN, yN) equal to (xD, yD), and the output is assigned to mbAddrN.

6.4.8.2 Derivation process for neighbouring 8x8 luma block

Input to this process is an 8x8 luma block index luma8x8BlkIdx.

The luma8x8BlkIdx specifies the 8x8 luma blocks of a macroblock in a raster scan.

Outputs of this process are

- mbAddrA: either equal to CurrMbAddr or the address of the macroblock to the left of the current macroblock and its availability status,
- luma8x8BlkIdxA: the index of the 8x8 luma block to the left of the 8x8 block with index luma8x8BlkIdx and its availability status,
- mbAddrB: either equal to CurrMbAddr or the address of the macroblock above the current macroblock and its availability status,
- luma8x8BlkIdxB: the index of the 8x8 luma block above the 8x8 block with index luma8x8BlkIdx and its availability status.

mbAddrN and luma8x8BlkIdxN (with N being A or B) are derived as follows.

- The difference of luma location (xD, yD) is set according to Table 6-2.
- The luma location (xN, yN) is specified by

$$xN = (\text{luma8x8BlkIdx} \% 2) * 8 + xD \quad (6-21)$$

$$yN = (\text{luma8x8BlkIdx} / 2) * 8 + yD \quad (6-22)$$

- The derivation process for neighbouring locations as specified in subclause 6.4.9 is invoked for luma locations with (xN, yN) as the input and the output is assigned to mbAddrN and (xW, yW).
- The variable luma8x8BlkIdxN is derived as follows.
 - If mbAddrN is not available, luma8x8BlkIdxN is marked as not available.
 - Otherwise (mbAddrN is available), the 8x8 luma block in the macroblock mbAddrN covering the luma location (xW, yW) is assigned to luma8x8BlkIdxN.

6.4.8.3 Derivation process for neighbouring 4x4 luma blocks

Input to this process is a 4x4 luma block index luma4x4BlkIdx.

Outputs of this process are

- mbAddrA: either equal to CurrMbAddr or the address of the macroblock to the left of the current macroblock and its availability status,
- luma4x4BlkIdxA: the index of the 4x4 luma block to the left of the 4x4 block with index luma4x4BlkIdx and its availability status,
- mbAddrB: either equal to CurrMbAddr or the address of the macroblock above the current macroblock and its availability status,
- luma4x4BlkIdxB: the index of the 4x4 luma block above the 4x4 block with index luma4x4BlkIdx and its availability status.

mbAddrN and luma4x4BlkIdxN (with N being A or B) are derived as follows.

- The difference of luma location (xD, yD) is set according to Table 6-2.
- The inverse 4x4 luma block scanning process as specified in subclause 6.4.3 is invoked with luma4x4BlkIdx as the input and (x, y) as the output.
- The luma location (xN, yN) is specified by

$$xN = x + xD \quad (6-23)$$

$$yN = y + yD \quad (6-24)$$

- The derivation process for neighbouring locations as specified in subclause 6.4.9 is invoked for luma locations with (xN, yN) as the input and the output is assigned to mbAddrN and (xW, yW).
- The variable luma4x4BlkIdxN is derived as follows.
 - If mbAddrN is not available, luma4x4BlkIdxN is marked as not available.
 - Otherwise (mbAddrN is available), the 4x4 luma block in the macroblock mbAddrN covering the luma location (xW, yW) is assigned to luma4x4BlkIdxN.

6.4.8.4 Derivation process for neighbouring 4x4 chroma blocks

Input to this process is a 4x4 chroma block index chroma4x4BlkIdx.

Outputs of this process are

- mbAddrA (either equal to CurrMbAddr or the address of the macroblock to the left of the current macroblock) and its availability status,
- chroma4x4BlkIdxA (the index of the 4x4 chroma block to the left of the 4x4 chroma block with index chroma4x4BlkIdx) and its availability status,

- mbAddrB (either equal to CurrMbAddr or the address of the macroblock above the current macroblock) and its availability status,
- chroma4x4BlkIdxB (the index of the 4x4 chroma block above the 4x4 chroma block with index chroma4x4BlkIdx) and its availability status.

mbAddrN and chroma4x4BlkIdxN (with N being A or B) are derived as follows.

- The difference of chroma location (xD, yD) is set according to Table 6-2.
- Depending on chroma_format_idc, the position (x, y) of the upper-left sample of the 4x4 chroma block with index chroma4x4BlkIdx is derived as follows

- If chroma_format_idc is equal to 1 or 2, the following applies

$$x = \text{InverseRasterScan}(\text{chroma4x4BlkIdx}, 4, 4, 8, 0) \quad (6-25)$$

$$y = \text{InverseRasterScan}(\text{chroma4x4BlkIdx}, 4, 4, 8, 1) \quad (6-26)$$

- Otherwise (chroma_format_idc is equal to 3), the following applies

$$x = \text{InverseRasterScan}(\text{chroma4x4BlkIdx} / 4, 8, 8, 16, 0) + \text{InverseRasterScan}(\text{chroma4x4BlkIdx} \% 4, 4, 4, 8, 0) \quad (6-27)$$

$$y = \text{InverseRasterScan}(\text{chroma4x4BlkIdx} / 4, 8, 8, 16, 1) + \text{InverseRasterScan}(\text{chroma4x4BlkIdx} \% 4, 4, 4, 8, 1) \quad (6-28)$$

- The chroma location (xN, yN) is specified by

$$xN = x + xD \quad (6-29)$$

$$yN = y + yD \quad (6-30)$$

- The derivation process for neighbouring locations as specified in subclause 6.4.9 is invoked for chroma locations with (xN, yN) as the input and the output is assigned to mbAddrN and (xW, yW).
- The variable chroma4x4BlkIdxN is derived as follows.
 - If mbAddrN is not available, chroma4x4BlkIdxN is marked as not available.
 - Otherwise (mbAddrN is available), the 4x4 chroma block in the macroblock mbAddrN covering the chroma location (xW, yW) is assigned to chroma4x4BlkIdxN.

6.4.8.5 Derivation process for neighbouring partitions

Inputs to this process are

- a macroblock partition index mbPartIdx
- a current sub-macroblock type currSubMbType
- a sub-macroblock partition index subMbPartIdx

Outputs of this process are

- mbAddrA\mbPartIdxA\subMbPartIdxA: specifying the macroblock or sub-macroblock partition to the left of the current macroblock and its availability status, or the sub-macroblock partition CurrMbAddr\mbPartIdx\subMbPartIdx and its availability status,

- mbAddrB\mbPartIdxB\subMbPartIdxB: specifying the macroblock or sub-macroblock partition above the current macroblock and its availability status, or the sub-macroblock partition CurrMbAddr\mbPartIdx\subMbPartIdx and its availability status,
- mbAddrC\mbPartIdxC\subMbPartIdxC: specifying the macroblock or sub-macroblock partition to the right-above of the current macroblock and its availability status, or the sub-macroblock partition CurrMbAddr\mbPartIdx\subMbPartIdx and its availability status,
- mbAddrD\mbPartIdxD\subMbPartIdxD: specifying the macroblock or sub-macroblock partition to the left-above of the current macroblock and its availability status, or the sub-macroblock partition CurrMbAddr\mbPartIdx\subMbPartIdx and its availability status.

mbAddrN, mbPartIdxN, and subMbPartIdx (with N being A, B, C, or D) are derived as follows.

- The inverse macroblock partition scanning process as described in subclause 6.4.2.1 is invoked with mbPartIdx as the input and (x, y) as the output.
- The location of the upper-left luma sample inside a macroblock partition (xS, yS) is derived as follows.
 - If mb_type is equal to P_8x8, P_8x8ref0 or B_8x8, the inverse sub-macroblock partition scanning process as described in subclause 6.4.2.2 is invoked with subMbPartIdx as the input and (xS, yS) as the output.
 - Otherwise, (xS, yS) are set to (0, 0).
- The variable predPartWidth in Table 6-2 is specified as follows.
 - If mb_type is equal to P_Skip, B_Skip, or B_Direct_16x16, predPartWidth = 16.
 - Otherwise, if mb_type is equal to B_8x8, the following applies.
 - If currSubMbType is equal to B_Direct_8x8, predPartWidth = 16.
NOTE 1 – When currSubMbType is equal to B_Direct_8x8 and direct_spatial_mv_pred_flag is equal to 1, the predicted motion vector is the predicted motion vector for the complete macroblock.
 - Otherwise, predPartWidth = SubMbPartWidth(sub_mb_type[mbPartIdx]).
 - Otherwise, if mb_type is equal to P_8x8 or P_8x8ref0, predPartWidth = SubMbPartWidth(sub_mb_type[mbPartIdx]).
 - Otherwise, predPartWidth = MbPartWidth(mb_type).
- The difference of luma location (xD, yD) is set according to Table 6-2.
- The neighbouring luma location (xN, yN) is specified by

$$xN = x + xS + xD \quad (6-31)$$

$$yN = y + yS + yD \quad (6-32)$$

- The derivation process for neighbouring locations as specified in subclause 6.4.9 is invoked for luma locations with (xN, yN) as the input and the output is assigned to mbAddrN and (xW, yW).
- Depending on mbAddrN, the following applies.
 - If mbAddrN is not available, the macroblock or sub-macroblock partition mbAddrN\mbPartIdxN\subMbPartIdxN is marked as not available.
 - Otherwise (mbAddrN is available), the following applies.
 - The macroblock partition in the macroblock mbAddrN covering the luma location (xW, yW) is assigned to mbPartIdxN and the sub-macroblock partition inside the macroblock partition mbPartIdxN covering the sample (xW, yW) in the macroblock mbAddrN is assigned to subMbPartIdxN.
 - When the partition given by mbPartIdxN and subMbPartIdxN is not yet decoded, the macroblock partition mbPartIdxN and the sub-macroblock partition subMbPartIdxN are marked as not available.

NOTE 2 – The latter condition is, for example, the case when mbPartIdx = 2, subMbPartIdx = 3, xD = 4, yD = -1, i.e., when neighbour C of the last 4x4 luma block of the third sub-macroblock is requested.

6.4.9 Derivation process for neighbouring locations

Input to this process is a luma or chroma location (x_N, y_N) expressed relative to the upper left corner of the current macroblock.

Outputs of this process are

- $mbAddrN$: either equal to $CurrMbAddr$ or to the address of neighbouring macroblock that contains (x_N, y_N) and its availability status,
- (x_W, y_W): the location (x_N, y_N) expressed relative to the upper-left corner of the macroblock $mbAddrN$ (rather than relative to the upper-left corner of the current macroblock).

Let $maxW$ and $maxH$ be variables specifying maximum values of the location components x_N, x_W , and y_N, y_W , respectively. $maxW$ and $maxH$ are derived as follows.

- If this process is invoked for neighbouring luma locations,

$$maxW = maxH = 16 \quad (6-33)$$

- Otherwise (this process is invoked for neighbouring chroma locations),

$$maxW = MbWidthC \quad (6-34)$$

$$maxH = MbHeightC \quad (6-35)$$

Depending on the variable $MbaffFrameFlag$, the neighbouring locations are derived as follows.

- If $MbaffFrameFlag$ is equal to 0, the specification for neighbouring locations in fields and non-MBAFF frames as described in subclause 6.4.9.1 is applied.
- Otherwise ($MbaffFrameFlag$ is equal to 1), the specification for neighbouring locations in MBAFF frames as described in subclause 6.4.9.2 is applied.

6.4.9.1 Specification for neighbouring locations in fields and non-MBAFF frames

The specifications in this subclause are applied when $MbaffFrameFlag$ is equal to 0.

The derivation process for neighbouring macroblock addresses and their availability in subclause 6.4.6 is invoked with $mbAddrA, mbAddrB, mbAddrC$, and $mbAddrD$ as well as their availability status as the output.

Table 6-3 specifies $mbAddrN$ depending on (x_N, y_N).

Table 6-3 – Specification of $mbAddrN$

x_N	y_N	$mbAddrN$
< 0	< 0	$mbAddrD$
< 0	$0 .. maxH - 1$	$mbAddrA$
$0 .. maxW - 1$	< 0	$mbAddrB$
$0 .. maxW - 1$	$0 .. maxH - 1$	$CurrMbAddr$
$> maxW - 1$	< 0	$mbAddrC$
$> maxW - 1$	$0 .. maxH - 1$	not available
	$> maxH - 1$	not available

The neighbouring location (x_W, y_W) relative to the upper-left corner of the macroblock $mbAddrN$ is derived as

$$x_W = (x_N + maxW) \% maxW \quad (6-36)$$

$$y_W = (y_N + maxH) \% maxH \quad (6-37)$$

6.4.9.2 Specification for neighbouring locations in MBAFF frames

The specifications in this subclause are applied when MbaffFrameFlag is equal to 1.

The derivation process for neighbouring macroblock addresses and their availability in subclause 6.4.7 is invoked with mbAddrA, mbAddrB, mbAddrC, and mbAddrD as well as their availability status as the output.

Table 6-4 specifies the macroblock addresses mbAddrN and yM in two ordered steps:

1. Specification of a macroblock address mbAddrX depending on (xN, yN) and the following variables:
 - The variable currMbFrameFlag is derived as follows.
 - If the macroblock with address CurrMbAddr is a frame macroblock, currMbFrameFlag is set equal to 1,
 - Otherwise (the macroblock with address CurrMbAddr is a field macroblock), currMbFrameFlag is set equal to 0.
 - The variable mbIsTopMbFlag is derived as follows.
 - If the macroblock with address CurrMbAddr is a top macroblock (CurrMbAddr % 2 is equal to 0), mbIsTopMbFlag is set equal to 1;
 - Otherwise (the macroblock with address CurrMbAddr is a bottom macroblock, CurrMbAddr % 2 is equal to 1), mbIsTopMbFlag is set equal to 0.
2. Depending on the availability of mbAddrX, the following applies.
 - If mbAddrX is not available, mbAddrN is marked as not available.
 - Otherwise (mbAddrX is available), mbAddrN is marked as available and Table 6-4 specifies mbAddrN and yM depending on (xN, yN), currMbFrameFlag, mbIsTopMbFlag, and the variable mbAddrXFrameFlag, which is derived as follows.
 - If the macroblock mbAddrX is a frame macroblock, mbAddrXFrameFlag is set equal to 1,
 - Otherwise (the macroblock mbAddrX is a field macroblock), mbAddrXFrameFlag is set equal to 0.

Unspecified values (na) of the above flags in Table 6-4 indicate that the value of the corresponding flag is not relevant for the current table rows.

Table 6-4 – Specification of mbAddrN and yM

x_N	y_N	currMbFrameFlag	mbIsTopMbFlag	mbAddrX	mbAddrXFrameFlag	additional condition	mbAddrN	y_M
< 0	< 0	1	1	mbAddrD			mbAddrD + 1	y_N
			0	mbAddrA	1		mbAddrA	y_N
		0	1	mbAddrD	0		mbAddrA + 1	$(y_N + \text{maxH}) \gg 1$
			0	mbAddrD	1		mbAddrD + 1	$2 * y_N$
< 0	$0 \dots \text{maxH} - 1$	1	1	mbAddrA	1		mbAddrD	y_N
					0	$y_N \% 2 == 0$	mbAddrA	$y_N \gg 1$
					0	$y_N \% 2 \neq 0$	mbAddrA + 1	$y_N \gg 1$
			0	mbAddrA	1		mbAddrA + 1	y_N
					0	$y_N \% 2 == 0$	mbAddrA	$(y_N + \text{maxH}) \gg 1$
					0	$y_N \% 2 \neq 0$	mbAddrA + 1	$(y_N + \text{maxH}) \gg 1$
		0	1	mbAddrA	1	$y_N < (\text{maxH} / 2)$	mbAddrA	$y_N \ll 1$
					0	$y_N \geq (\text{maxH} / 2)$	mbAddrA + 1	$(y_N \ll 1) - \text{maxH}$
			0	mbAddrA	1		mbAddrA	y_N
					0	$y_N < (\text{maxH} / 2)$	mbAddrA	$(y_N \ll 1) + 1$
$0 \dots \text{maxW} - 1$	< 0	1	1	mbAddrB			mbAddrA + 1	y_N
			0	CurrMbAddr			CurrMbAddr - 1	y_N
		0	1	mbAddrB	1		mbAddrB + 1	$2 * y_N$
			0	mbAddrB	0		mbAddrB	y_N
$0 \dots \text{maxW} - 1$	$0 \dots \text{maxH} - 1$			CurrMbAddr			mbAddrB + 1	y_N
> $\text{maxW} - 1$	< 0	1	1	mbAddrC			CurrMbAddr	y_N
			0	not available			mbAddrC + 1	y_N
		0	1	mbAddrC	1		not available	na
			0	mbAddrC	0		mbAddrC + 1	$2 * y_N$
> $\text{maxW} - 1$	$0 \dots \text{maxH} - 1$			not available			mbAddrC	y_N
	> $\text{maxH} - 1$			not available			mbAddrC + 1	y_N
				not available			not available	na

The neighbouring luma location (x_W, y_W) relative to the upper-left corner of the macroblock mbAddrN is derived as

$$x_W = (x_N + \text{maxW}) \% \text{maxW} \quad (6-38)$$

$$y_W = (y_M + \text{maxH}) \% \text{maxH} \quad (6-39)$$

7 Syntax and semantics

7.1 Method of specifying syntax in tabular form

The syntax tables specify a superset of the syntax of all allowed bitstreams. Additional constraints on the syntax may be specified, either directly or indirectly, in other clauses.

NOTE – An actual decoder should implement means for identifying entry points into the bitstream and means to identify and handle non-conforming bitstreams. The methods for identifying and handling errors and other such situations are not specified here.

The following table lists examples of pseudo code used to describe the syntax. When **syntax_element** appears, it specifies that a syntax element is parsed from the bitstream and the bitstream pointer is advanced to the next position beyond the syntax element in the bitstream parsing process.

	C	Descriptor
/* A statement can be a syntax element with an associated syntax category and descriptor or can be an expression used to specify conditions for the existence, type, and quantity of syntax elements, as in the following two examples */		
syntax_element	3	ue(v)
conditioning statement		
/* A group of statements enclosed in curly brackets is a compound statement and is treated functionally as a single statement. */		
{		
statement		
statement		
...		
}		
/* A “while” structure specifies a test of whether a condition is true, and if true, specifies evaluation of a statement (or compound statement) repeatedly until the condition is no longer true */		
while(condition)		
statement		
/* A “do ... while” structure specifies evaluation of a statement once, followed by a test of whether a condition is true, and if true, specifies repeated evaluation of the statement until the condition is no longer true */		
do		
statement		
while(condition)		
/* An “if ... else” structure specifies a test of whether a condition is true, and if the condition is true, specifies evaluation of a primary statement, otherwise, specifies evaluation of an alternative statement. The “else” part of the structure and the associated alternative statement is omitted if no alternative statement evaluation is needed */		
if(condition)		
primary statement		
else		
alternative statement		
/* A “for” structure specifies evaluation of an initial statement, followed by a test of a condition, and if the condition is true, specifies repeated evaluation of a primary statement followed by a subsequent statement until the condition is no longer true. */		
for(initial statement; condition; subsequent statement)		
primary statement		

7.2 Specification of syntax functions, categories, and descriptors

The functions presented here are used in the syntactical description. These functions assume the existence of a bitstream pointer with an indication of the position of the next bit to be read by the decoding process from the bitstream.

`byte_aligned()` is specified as follows.

- If the current position in the bitstream is on a byte boundary, i.e., the next bit in the bitstream is the first bit in a byte, the return value of `byte_aligned()` is equal to TRUE.
- Otherwise, the return value of `byte_aligned()` is equal to FALSE.

`more_data_in_byte_stream()`, which is used only in the byte stream NAL unit syntax structure specified in Annex B, is specified as follows.

- If more data follow in the byte stream, the return value of `more_data_in_byte_stream()` is equal to TRUE.
- Otherwise, the return value of `more_data_in_byte_stream()` is equal to FALSE.

`more_rbsp_data()` is specified as follows.

- If there is more data in an RBSP before `rbsp_trailing_bits()`, the return value of `more_rbsp_data()` is equal to TRUE.
- Otherwise, the return value of `more_rbsp_data()` is equal to FALSE.

The method for enabling determination of whether there is more data in the RBSP is specified by the application (or in Annex B for applications that use the byte stream format).

`more_rbsp_trailing_data()` is specified as follows.

- If there is more data in an RBSP, the return value of `more_rbsp_trailing_data()` is equal to TRUE.
- Otherwise, the return value of `more_rbsp_trailing_data()` is equal to FALSE.

`next_bits(n)` provides the next bits in the bitstream for comparison purposes, without advancing the bitstream pointer. Provides a look at the next *n* bits in the bitstream with *n* being its argument. When used within the byte stream as specified in Annex B, `next_bits(n)` returns a value of 0 if fewer than *n* bits remain within the byte stream.

`read_bits(n)` reads the next *n* bits from the bitstream and advances the bitstream pointer by *n* bit positions. When *n* is equal to 0, `read_bits(n)` is specified to return a value equal to 0 and to not advance the bitstream pointer.

Categories (labelled in the table as C) specify the partitioning of slice data into at most three slice data partitions. Slice data partition A contains all syntax elements of category 2. Slice data partition B contains all syntax elements of category 3. Slice data partition C contains all syntax elements of category 4. The meaning of other category values is not specified. For some syntax elements, two category values, separated by a vertical bar, are used. In these cases, the category value to be applied is further specified in the text. For syntax structures used within other syntax structures, the categories of all syntax elements found within the included syntax structure are listed, separated by a vertical bar. A syntax element or syntax structure with category marked as "All" is present within all syntax structures that include that syntax element or syntax structure. For syntax structures used within other syntax structures, a numeric category value provided in a syntax table at the location of the inclusion of a syntax structure containing a syntax element with category marked as "All" is considered to apply to the syntax elements with category "All".

The following descriptors specify the parsing process of each syntax element. For some syntax elements, two descriptors, separated by a vertical bar, are used. In these cases, the left descriptors apply when `entropy_coding_mode_flag` is equal to 0 and the right descriptor applies when `entropy_coding_mode_flag` is equal to 1.

- `ae(v)`: context-adaptive arithmetic entropy-coded syntax element. The parsing process for this descriptor is specified in subclause 9.3.
- `b(8)`: byte having any pattern of bit string (8 bits). The parsing process for this descriptor is specified by the return value of the function `read_bits(8)`.
- `ce(v)`: context-adaptive variable-length entropy-coded syntax element with the left bit first. The parsing process for this descriptor is specified in subclause 9.2.
- `f(n)`: fixed-pattern bit string using *n* bits written (from left to right) with the left bit first. The parsing process for this descriptor is specified by the return value of the function `read_bits(n)`.
- `i(n)`: signed integer using *n* bits. When *n* is "v" in the syntax table, the number of bits varies in a manner dependent on the value of other syntax elements. The parsing process for this descriptor is specified by the

return value of the function `read_bits(n)` interpreted as a two's complement integer representation with most significant bit written first.

- `me(v)`: mapped Exp-Golomb-coded syntax element with the left bit first. The parsing process for this descriptor is specified in subclause 9.1.
- `se(v)`: signed integer Exp-Golomb-coded syntax element with the left bit first. The parsing process for this descriptor is specified in subclause 9.1.
- `te(v)`: truncated Exp-Golomb-coded syntax element with left bit first. The parsing process for this descriptor is specified in subclause 9.1.
- `u(n)`: unsigned integer using `n` bits. When `n` is "v" in the syntax table, the number of bits varies in a manner dependent on the value of other syntax elements. The parsing process for this descriptor is specified by the return value of the function `read_bits(n)` interpreted as a binary representation of an unsigned integer with most significant bit written first.
- `ue(v)`: unsigned integer Exp-Golomb-coded syntax element with the left bit first. The parsing process for this descriptor is specified in subclause 9.1.

7.3 Syntax in tabular form

7.3.1 NAL unit syntax

<code>nal_unit(NumBytesInNALunit) {</code>	C	Descriptor
forbidden_zero_bit	All	f(1)

7.4 Semantics

Semantics associated with the syntax structures and with the syntax elements within these structures are specified in this subclause. When the semantics of a syntax element are specified using a table or a set of tables, any values that are not specified in the table(s) shall not be present in the bitstream unless otherwise specified in this Recommendation | International Standard.

7.4.1 NAL unit semantics

NOTE 1 – The VCL is specified to efficiently represent the content of the video data. The NAL is specified to format that data and provide header information in a manner appropriate for conveyance on a variety of communication channels or storage media. All data are contained in NAL units, each of which contains an integer number of bytes. A NAL unit specifies a generic format for use in both packet-oriented and bitstream systems. The format of NAL units for both packet-oriented transport and byte stream is identical except that each NAL unit can be preceded by a start code prefix and extra padding bytes in the byte stream format.

NumBytesInNALunit specifies the size of the NAL unit in bytes. This value is required for decoding of the NAL unit. Some form of demarcation of NAL unit boundaries is necessary to enable inference of NumBytesInNALunit. One such demarcation method is specified in Annex B for the byte stream format. Other methods of demarcation may be specified outside of this Recommendation | International Standard.

forbidden_zero_bit shall be equal to 0.

nal_ref_idc not equal to 0 specifies that the content of the NAL unit contains a sequence parameter set or a picture parameter set or a slice of a reference picture or a slice data partition of a reference picture.

nal_ref_idc equal to 0 for a NAL unit containing a slice or slice data partition indicates that the slice or slice data partition is part of a non-reference picture.

nal_ref_idc shall not be equal to 0 for sequence parameter set or sequence parameter set extension or picture parameter set NAL units. When nal_ref_idc is equal to 0 for one slice or slice data partition NAL unit of a particular picture, it shall be equal to 0 for all slice and slice data partition NAL units of the picture.

nal_ref_idc shall not be equal to 0 for IDR NAL units, i.e., NAL units with nal_unit_type equal to 5.

nal_ref_idc shall be equal to 0 for all NAL units having nal_unit_type equal to 6, 9, 10, 11, or 12.

nal_unit_type specifies the type of RBSP data structure contained in the NAL unit as specified in Table 7-1. VCL NAL units are specified as those NAL units having nal_unit_type equal to 1 to 5, inclusive. All remaining NAL units are called non-VCL NAL units.

The column marked "C" in Table 7-1 lists the categories of the syntax elements that may be present in the NAL unit. In addition, syntax elements with syntax category "All" may be present, as determined by the syntax and semantics of the RBSP data structure. The presence or absence of any syntax elements of a particular listed category is determined from the syntax and semantics of the associated RBSP data structure. nal_unit_type shall not be equal to 3 or 4 unless at least one syntax element is present in the RBSP data structure having a syntax element category value equal to the value of nal_unit_type and not categorized as "All".

Table 7-1 – NAL unit type codes

nal_unit_type	Content of NAL unit and RBSP syntax structure	C
0	Unspecified	
1	Coded slice of a non-IDR picture slice_layer_without_partitioning_rbsp()	2, 3, 4
2	Coded slice data partition A slice_data_partition_a_layer_rbsp()	2

11	End of stream end_of_stream_rbsp()	8
12	Filler data filler_data_rbsp()	9
13	Sequence parameter set extension seq_parameter_set_extension_rbsp()	10
14..18	Reserved	
19	Coded slice of an auxiliary coded picture without partitioning slice_layer_without_partitioning_rbsp()	2, 3, 4
20..23	Reserved	
24..31	Unspecified	

NAL units having nal_unit_type equal to 13 and 19 may be discarded by decoders without affecting the decoding process for NAL units having nal_unit_type not equal to 13 or 19 and without affecting conformance to this Recommendation | International Standard.

NAL units that use nal_unit_type equal to 0 or in the range of 24..31, inclusive, shall not affect the decoding process specified in this Recommendation | International Standard.

NOTE 2 – NAL unit types 0 and 24..31 may be used as determined by the application. No decoding process for these values of nal_unit_type is specified in this Recommendation | International Standard.

Decoders shall ignore (remove from the bitstream and discard) the contents of all NAL units that use reserved values of nal_unit_type.

NOTE 3 – This requirement allows future definition of compatible extensions to this Recommendation | International Standard.

In the text, coded slice NAL unit collectively refers to a coded slice of a non-IDR picture NAL unit or to a coded slice of an IDR picture NAL unit.

When the value of `nal_unit_type` is equal to 5 for a NAL unit containing a slice of a coded picture, the value of `nal_unit_type` shall be 5 in all other VCL NAL units of the same coded picture. Such a picture is referred to as an IDR picture.

NOTE 4 – Slice data partitioning cannot be used for IDR pictures.

`rbsp_byte[i]` is the *i*-th byte of an RBSP. An RBSP is specified as an ordered sequence of bytes as follows.

The RBSP contains an SODB as follows.

- If the SODB is empty (i.e., zero bits in length), the RBSP is also empty.
- Otherwise, the RBSP contains the SODB as follows.
 - 1) The first byte of the RBSP contains the (most significant, left-most) eight bits of the SODB; the next byte of the RBSP shall contain the next eight bits of the SODB, etc., until fewer than eight bits of the SODB remain.
 - 2) `rbsp_trailing_bits()` are present after the SODB as follows:
 - i) The first (most significant, left-most) bits of the final RBSP byte contains the remaining bits of the SODB, (if any)
 - ii) The next bit consists of a single `rbsp_stop_one_bit` equal to 1, and
 - iii) When the `rbsp_stop_one_bit` is not the last bit of a byte-aligned byte, one or more `rbsp_alignment_zero_bit` is present to result in byte alignment.
 - 3) One or more `cabac_zero_word` 16-bit syntax elements equal to 0x0000 may be present in some RBSPs after the `rbsp_trailing_bits()` at the end of the RBSP.

Syntax structures having these RBSP properties are denoted in the syntax tables using an "`_rbsp`" suffix. These structures shall be carried within NAL units as the content of the `rbsp_byte[i]` data bytes. The association of the RBSP syntax structures to the NAL units shall be as specified in Table 7-1.

NOTE 5 – When the boundaries of the RBSP are known, the decoder can extract the SODB from the RBSP by concatenating the bits of the bytes of the RBSP and discarding the `rbsp_stop_one_bit`, which is the last (least significant, right-most) bit equal to 1, and discarding any following (less significant, farther to the right) bits that follow it, which are equal to 0. The data necessary for the decoding process is contained in the SODB part of the RBSP.

`emulation_prevention_three_byte` is a byte equal to 0x03. When an `emulation_prevention_three_byte` is present in the NAL unit, it shall be discarded by the decoding process.

The last byte of the NAL unit shall not be equal to 0x00.

Within the NAL unit, the following three-byte sequences shall not occur at any byte-aligned position:

- 0x000000
- 0x000001
- 0x000002

Within the NAL unit, any four-byte sequence that starts with 0x000003 other than the following sequences shall not occur at any byte-aligned position:

- 0x00000300
- 0x00000301
- 0x00000302
- 0x00000303

NOTE 6 – When `nal_unit_type` is equal to 0, particular care must be exercised in the design of encoders to avoid the presence of the above-listed three-byte and four-byte patterns at the beginning of the NAL unit syntax structure, as the syntax element `emulation_prevention_three_byte` cannot be the third byte of a NAL unit.

7.4.1.1 Encapsulation of an SODB within an RBSP (informative)

This subclause does not form an integral part of this Recommendation | International Standard.

The form of encapsulation of an SODB within an RBSP and the use of the `emulation_prevention_three_byte` for encapsulation of an RBSP within a NAL unit is specified for the following purposes:

- to prevent the emulation of start codes within NAL units while allowing any arbitrary SODB to be represented within a NAL unit,
- to enable identification of the end of the SODB within the NAL unit by searching the RBSP for the `rbsp_stop_one_bit` starting at the end of the RBSP, and

- to enable a NAL unit to have a size larger than that of the SODB under some circumstances (using one or more `cabac_zero_word`).

The encoder can produce a NAL unit from an RBSP by the following procedure:

The RBSP data is searched for byte-aligned bits of the following binary patterns:

'00000000 00000000 000000xx' (where xx represents any 2 bit pattern: 00, 01, 10, or 11),

and a byte equal to 0x03 is inserted to replace these bit patterns with the patterns

'00000000 00000000 00000011 000000xx',

and finally, when the last byte of the RBSP data is equal to 0x00 (which can only occur when the RBSP ends in a `cabac_zero_word`), a final byte equal to 0x03 is appended to the end of the data.

The resulting sequence of bytes is then prefixed with the first byte of the NAL unit containing the indication of the type of RBSP data structure it contains. This results in the construction of the entire NAL unit.

This process can allow any SODB to be represented in a NAL unit while ensuring that

- no byte-aligned start code prefix is emulated within the NAL unit, and
- no sequence of 8 zero-valued bits followed by a start code prefix, regardless of byte-alignment, is emulated within the NAL unit.

7.4.1.2 Order of NAL units and association to coded pictures, access units, and video sequences

This subclause specifies constraints on the order of NAL units in the bitstream. Any order of NAL units in the bitstream obeying these constraints is referred to in the text as the decoding order of NAL units. Within a NAL unit, the syntax in subclauses 7.3, D.1, and E.1 specifies the decoding order of syntax elements. Decoders conforming to this Recommendation | International Standard shall be capable of receiving NAL units and their syntax elements in decoding order.

7.4.1.2.1 Order of sequence and picture parameter set RBSPs and their activation

NOTE 1 – The sequence and picture parameter set mechanism decouples the transmission of infrequently changing information from the transmission of coded macroblock data. Sequence and picture parameter sets may, in some applications, be conveyed "out-of-band" using a reliable transport mechanism.

A picture parameter set RBSP includes parameters that can be referred to by the coded slice NAL units or coded slice data partition A NAL units of one or more coded pictures. Each picture parameter set RBSP is initially considered not active at the start of the operation of the decoding process. At most one picture parameter set RBSP is considered active at any given moment during the operation of the decoding process, and the activation of any particular picture parameter set RBSP results in the deactivation of the previously-active picture parameter set RBSP (if any).

When a picture parameter set RBSP (with a particular value of `pic_parameter_set_id`) is not active and it is referred to by a coded slice NAL unit or coded slice data partition A NAL unit (using that value of `pic_parameter_set_id`), it is activated. This picture parameter set RBSP is called the active picture parameter set RBSP until it is deactivated by the activation of another picture parameter set RBSP. A picture parameter set RBSP, with that particular value of `pic_parameter_set_id`, shall be available to the decoding process prior to its activation.

Any picture parameter set NAL unit containing the value of `pic_parameter_set_id` for the active picture parameter set RBSP shall have the same content as that of the active picture parameter set RBSP unless it follows the last VCL NAL unit of a coded picture and precedes the first VCL NAL unit of another coded picture.

A sequence parameter set RBSP includes parameters that can be referred to by one or more picture parameter set RBSPs or one or more SEI NAL units containing a buffering period SEI message. Each sequence parameter set RBSP is initially considered not active at the start of the operation of the decoding process. At most one sequence parameter set RBSP is considered active at any given moment during the operation of the decoding process, and the activation of any particular sequence parameter set RBSP results in the deactivation of the previously-active sequence parameter set RBSP (if any).

When a sequence parameter set RBSP (with a particular value of `seq_parameter_set_id`) is not already active and it is referred to by activation of a picture parameter set RBSP (using that value of `seq_parameter_set_id`) or is referred to by an SEI NAL unit containing a buffering period SEI message (using that value of `seq_parameter_set_id`), it is activated. This sequence parameter set RBSP is called the active sequence parameter set RBSP until it is deactivated by the activation of another sequence parameter set RBSP. A sequence parameter set RBSP, with that particular value of `seq_parameter_set_id`, shall be available to the decoding process prior to its activation. An activated sequence parameter set RBSP shall remain active for the entire coded video sequence.

NOTE 2 – Because an IDR access unit begins a new coded video sequence and an activated sequence parameter set RBSP must remain active for the entire coded video sequence, a sequence parameter set RBSP can only be activated by a buffering period SEI message when the buffering period SEI message is part of an IDR access unit.

Any sequence parameter set NAL unit containing the value of `seq_parameter_set_id` for the active sequence parameter set RBSP shall have the same content as that of the active sequence parameter set RBSP unless it follows the last access unit of a coded video sequence and precedes the first VCL NAL unit and the first SEI NAL unit containing a buffering period SEI message (when present) of another coded video sequence.

NOTE 3 – If picture parameter set RBSP or sequence parameter set RBSP are conveyed within the bitstream, these constraints impose an order constraint on the NAL units that contain the picture parameter set RBSP or sequence parameter set RBSP, respectively. Otherwise (picture parameter set RBSP or sequence parameter set RBSP are conveyed by other means not specified in this Recommendation | International Standard), they must be available to the decoding process in a timely fashion such that these constraints are obeyed.

When present, a sequence parameter set extension RBSP includes parameters having a similar function to those of a sequence parameter set RBSP. For purposes of establishing constraints on the syntax elements of the sequence parameter set extension RBSP and for purposes of determining activation of a sequence parameter set extension RBSP, the sequence parameter set extension RBSP shall be considered part of the preceding sequence parameter set RBSP with the same value of `seq_parameter_set_id`. When a sequence parameter set RBSP is present that is not followed by a sequence parameter set extension RBSP with the same value of `seq_parameter_set_id` prior to the activation of the sequence parameter set RBSP, the sequence parameter set extension RBSP and its syntax elements shall be considered not present for the active sequence parameter set RBSP.

All constraints that are expressed on the relationship between the values of the syntax elements (and the values of variables derived from those syntax elements) in sequence parameter sets and picture parameter sets and other syntax elements are expressions of constraints that apply only to the active sequence parameter set and the active picture parameter set. If any sequence parameter set RBSP is present that is not activated in the bitstream, its syntax elements shall have values that would conform to the specified constraints if it were activated by reference in an otherwise-conforming bitstream. If any picture parameter set RBSP is present that is not ever activated in the bitstream, its syntax elements shall have values that would conform to the specified constraints if it were activated by reference in an otherwise-conforming bitstream.

During operation of the decoding process (see clause 8), the values of parameters of the active picture parameter set and the active sequence parameter set shall be considered in effect. For interpretation of SEI messages, the values of the parameters of the picture parameter set and sequence parameter set that are active for the operation of the decoding process for the VCL NAL units of the primary coded picture in the same access unit shall be considered in effect unless otherwise specified in the SEI message semantics.

7.4.1.2.2 Order of access units and association to coded video sequences

A bitstream conforming to this Recommendation | International Standard consists of one or more coded video sequences.

A coded video sequence consists of one or more access units. The order of NAL units and coded pictures and their association to access units is described in subclause 7.4.1.2.3.

The first access unit of each coded video sequence is an IDR access unit. All subsequent access units in the coded video sequence are non-IDR access units.

The values of picture order count for the coded pictures in consecutive access units in decoding order containing non-reference pictures shall be non-decreasing.

When present, an access unit following an access unit that contains an end of sequence NAL unit shall be an IDR access unit.

When an SEI NAL unit contains data that pertain to more than one access unit (for example, when the SEI NAL unit has a coded video sequence as its scope), it shall be contained in the first access unit to which it applies.

When an end of stream NAL unit is present in an access unit, this access unit shall be the last access unit in the bitstream and the end of stream NAL unit shall be the last NAL unit in that access unit.

7.4.1.2.3 Order of NAL units and coded pictures and association to access units

An access unit consists of one primary coded picture, zero or more corresponding redundant coded pictures, and zero or more non-VCL NAL units. The association of VCL NAL units to primary or redundant coded pictures is described in subclause 7.4.1.2.5.

The first access unit in the bitstream starts with the first NAL unit of the bitstream.

The first of any of the following NAL units after the last VCL NAL unit of a primary coded picture specifies the start of a new access unit.

- access unit delimiter NAL unit (when present)
- sequence parameter set NAL unit (when present)
- picture parameter set NAL unit (when present)
- SEI NAL unit (when present)
- NAL units with `nal_unit_type` in the range of 14 to 18, inclusive
- first VCL NAL unit of a primary coded picture (always present)

The constraints for the detection of the first VCL NAL unit of a primary coded picture are specified in subclause 7.4.1.2.4.

The following constraints shall be obeyed by the order of the coded pictures and non-VCL NAL units within an access unit.

- When an access unit delimiter NAL unit is present, it shall be the first NAL unit. There shall be at most one access unit delimiter NAL unit in any access unit.
- When any SEI NAL units are present, they shall precede the primary coded picture.
- When an SEI NAL unit containing a buffering period SEI message is present, the buffering period SEI message shall be the first SEI message payload of the first SEI NAL unit in the access unit
- The primary coded picture shall precede the corresponding redundant coded pictures.
- When redundant coded pictures are present, they shall be ordered in ascending order of the value of `redundant_pic_cnt`.
- When a sequence parameter set extension NAL unit is present, it shall be the next NAL unit after a sequence parameter set NAL unit having the same value of `seq_parameter_set_id` as in the sequence parameter set extension NAL unit.
- When one or more coded slice of an auxiliary coded picture without partitioning NAL units is present, they shall follow the primary coded picture and all redundant coded pictures (if any).
- When an end of sequence NAL unit is present, it shall follow the primary coded picture and all redundant coded pictures (if any) and all coded slice of an auxiliary coded picture without partitioning NAL units (if any).
- When an end of stream NAL unit is present, it shall be the last NAL unit.
- NAL units having `nal_unit_type` equal to 0, 12, or in the range of 20 to 31, inclusive, shall not precede the first VCL NAL unit of the primary coded picture.

NOTE 1 – Sequence parameter set NAL units or picture parameter set NAL units may be present in an access unit, but cannot follow the last VCL NAL unit of the primary coded picture within the access unit, as this condition would specify the start of a new access unit.

NOTE 2 – When a NAL unit having `nal_unit_type` equal to 7 or 8 is present in an access unit, it may or may not be referred to in the coded pictures of the access unit in which it is present, and may be referred to in coded pictures of subsequent access units.

The structure of access units not containing any NAL units with `nal_unit_type` equal to 0, 7, 8, or in the range of 12 to 18, inclusive, or in the range of 20 to 31, inclusive, is shown in Figure 7-1.

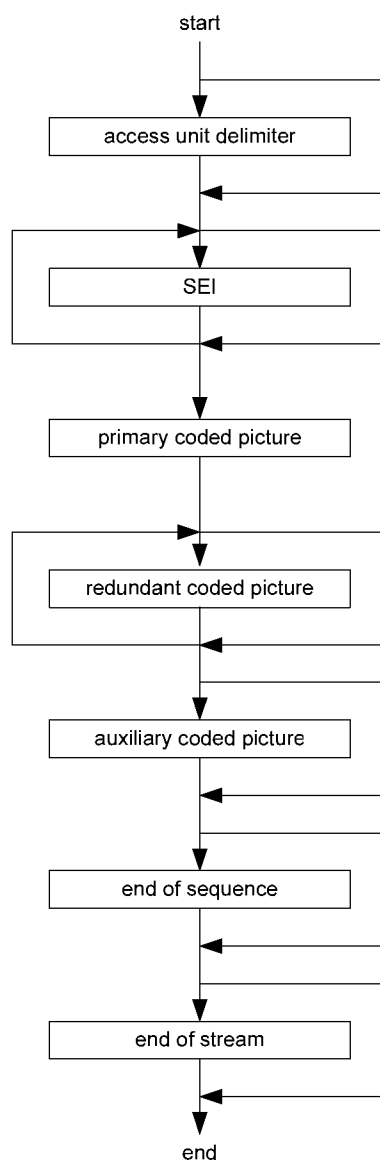

Figure 7-1 – Structure of an access unit not containing any NAL units with nal_unit_type equal to 0, 7, 8, or in the range of 12 to 18, inclusive, or in the range of 20 to 31, inclusive

7.4.1.2.4 Detection of the first VCL NAL unit of a primary coded picture

This subclause specifies constraints on VCL NAL unit syntax that are sufficient to enable the detection of the first VCL NAL unit of each primary coded picture.

Any coded slice NAL unit or coded slice data partition A NAL unit of the primary coded picture of the current access unit shall be different from any coded slice NAL unit or coded slice data partition A NAL unit of the primary coded picture of the previous access unit in one or more of the following ways.

- frame_num differs in value. The value of frame_num used to test this condition is the value of frame_num that appears in the syntax of the slice header, regardless of whether that value is inferred to have been equal to 0 for subsequent use in the decoding process due to the presence of memory_management_control_operation equal to 5.

NOTE 1 – A consequence of the above statement is that a primary coded picture having frame_num equal to 1 cannot contain a memory_management_control_operation equal to 5 unless some other condition listed below is fulfilled for the next primary coded picture that follows after it (if any).

- pic_parameter_set_id differs in value.
- field_pic_flag differs in value.

- `bottom_field_flag` is present in both and differs in value.
- `nal_ref_idc` differs in value with one of the `nal_ref_idc` values being equal to 0.
- `pic_order_cnt_type` is equal to 0 for both and either `pic_order_cnt_lsb` differs in value, or `delta_pic_order_cnt_bottom` differs in value.
- `pic_order_cnt_type` is equal to 1 for both and either `delta_pic_order_cnt[0]` differs in value, or `delta_pic_order_cnt[1]` differs in value.
- `nal_unit_type` differs in value with one of the `nal_unit_type` values being equal to 5.
- `nal_unit_type` is equal to 5 for both and `idr_pic_id` differs in value.

NOTE 2 – Some of the VCL NAL units in redundant coded pictures or some non-VCL NAL units (e.g. an access unit delimiter NAL unit) may also be used for the detection of the boundary between access units, and may therefore aid in the detection of the start of a new primary coded picture.

7.4.1.2.5 Order of VCL NAL units and association to coded pictures

Each VCL NAL unit is part of a coded picture.

The order of the VCL NAL units within a coded IDR picture is constrained as follows.

- If arbitrary slice order is allowed as specified in Annex A, coded slice of an IDR picture NAL units may have any order relative to each other.
- Otherwise (arbitrary slice order is not allowed), the order of coded slice of an IDR picture NAL units shall be in the order of increasing macroblock address for the first macroblock of each coded slice of an IDR picture NAL unit.

The order of the VCL NAL units within a coded non-IDR picture is constrained as follows.

- If arbitrary slice order is allowed as specified in Annex A, coded slice of a non-IDR picture NAL units or coded slice data partition A NAL units may have any order relative to each other. A coded slice data partition A NAL unit with a particular value of `slice_id` shall precede any present coded slice data partition B NAL unit with the same value of `slice_id`. A coded slice data partition A NAL unit with a particular value of `slice_id` shall precede any present coded slice data partition C NAL unit with the same value of `slice_id`. When a coded slice data partition B NAL unit with a particular value of `slice_id` is present, it shall precede any present coded slice data partition C NAL unit with the same value of `slice_id`.
- Otherwise (arbitrary slice order is not allowed), the order of coded slice of a non-IDR picture NAL units or coded slice data partition A NAL units shall be in the order of increasing macroblock address for the first macroblock of each coded slice of a non-IDR picture NAL unit or coded slice data partition A NAL unit. A coded slice data partition A NAL unit with a particular value of `slice_id` shall immediately precede any present coded slice data partition B NAL unit with the same value of `slice_id`. A coded slice data partition A NAL unit with a particular value of `slice_id` shall immediately precede any present coded slice data partition C NAL unit with the same value of `slice_id`, when a coded slice data partition B NAL unit with the same value of `slice_id` is not present. When a coded slice data partition B NAL unit with a particular value of `slice_id` is present, it shall immediately precede any present coded slice data partition C NAL unit with the same value of `slice_id`.

NAL units having `nal_unit_type` equal to 12 may be present in the access unit but shall not precede the first VCL NAL unit of the primary coded picture within the access unit.

NAL units having `nal_unit_type` equal to 0 or in the range of 24 to 31, inclusive, which are unspecified, may be present in the access unit but shall not precede the first VCL NAL unit of the primary coded picture within the access unit.

NAL units having `nal_unit_type` in the range of 20 to 23, inclusive, which are reserved, shall not precede the first VCL NAL unit of the primary coded picture within the access unit (when specified in the future by ITU-T | ISO/IEC).

7.4.2 Raw byte sequence payloads and RBSP trailing bits semantics

7.4.2.1 Sequence parameter set RBSP semantics

profile_idc and **level_idc** indicate the profile and level to which the bitstream conforms, as specified in Annex A.

constraint_set0_flag equal to 1 indicates that the bitstream obeys all constraints specified in subclause A.2.1. **constraint_set0_flag** equal to 0 indicates that the bitstream may or may not obey all constraints specified in subclause A.2.1.

constraint_set1_flag equal to 1 indicates that the bitstream obeys all constraints specified in subclause A.2.2. **constraint_set1_flag** equal to 0 indicates that the bitstream may or may not obey all constraints specified in subclause A.2.2.

constraint_set2_flag equal to 1 indicates that the bitstream obeys all constraints specified in subclause A.2.3. **constraint_set2_flag** equal to 0 indicates that the bitstream may or may not obey all constraints specified in subclause A.2.3.

NOTE 1 – When one or more than one of **constraint_set0_flag**, **constraint_set1_flag**, or **constraint_set2_flag** are equal to 1, the bitstream must obey the constraints of all of the indicated subclauses of subclause A.2. When **profile_idc** is equal to 100, 110, 122, or 144, the values of **constraint_set0_flag**, **constraint_set1_flag**, and **constraint_set2_flag** must all be equal to 0.

constraint_set3_flag indicates the following.

- If **profile_idc** is equal to 66, 77, or 88 and **level_idc** is equal to 11, **constraint_set3_flag** equal to 1 indicates that the bitstream obeys all constraints specified in Annex A for level 1b and **constraint_set3_flag** equal to 0 indicates that the bitstream may or may not obey all constraints specified in Annex A for level 1b.
- Otherwise (**profile_idc** is equal to 100, 110, 122, or 144 or **level_idc** is not equal to 11), the value of 1 for **constraint_set3_flag** is reserved for future use by ITU-T | ISO/IEC. **constraint_set3_flag** shall be equal to 0 in bitstreams conforming to this Recommendation | International Standard when **profile_idc** is equal to 100, 110, 122, or 144 or **level_idc** is not equal to 11. Decoders conforming to this Recommendation | International Standard shall ignore the value of **constraint_set3_flag** when **profile_idc** is equal to 100, 110, 122, or 144 or **level_idc** is not equal to 11.

reserved_zero_4bits shall be equal to 0. Other values of **reserved_zero_4bits** may be specified in the future by ITU-T | ISO/IEC. Decoders shall ignore the value of **reserved_zero_4bits**.

seq_parameter_set_id identifies the sequence parameter set that is referred to by the picture parameter set. The value of **seq_parameter_set_id** shall be in the range of 0 to 31, inclusive.

NOTE 2 – When feasible, encoders should use distinct values of **seq_parameter_set_id** when the values of other sequence parameter set syntax elements differ rather than changing the values of the syntax elements associated with a specific value of **seq_parameter_set_id**.

chroma_format_idc specifies the chroma sampling relative to the luma sampling as specified in subclause 6.2. The value of **chroma_format_idc** shall be in the range of 0 to 3, inclusive. When **chroma_format_idc** is not present, it shall be inferred to be equal to 1 (4:2:0 chroma format).

residual_colour_transform_flag equal to 1 specifies that the residual colour transform is applied as specified in subclause 8.5. **residual_colour_transform_flag** equal to 0 specifies that the residual colour transform is not applied. When **residual_colour_transform_flag** is not present, it shall be inferred to be equal to 0.

bit_depth_luma_minus8 specifies the bit depth of the samples of the luma array and the value of the luma quantisation parameter range offset $QpBdOffset_Y$, as specified by

$$BitDepth_Y = 8 + bit_depth_luma_minus8 \quad (7-1)$$

$$QpBdOffset_Y = 6 * bit_depth_luma_minus8 \quad (7-2)$$

When **bit_depth_luma_minus8** is not present, it shall be inferred to be equal to 0. **bit_depth_luma_minus8** shall be in the range of 0 to 4, inclusive.

bit_depth_chroma_minus8 specifies the bit depth of the samples of the chroma arrays and the value of the chroma quantisation parameter range offset $QpBdOffset_C$, as specified by

$$BitDepth_C = 8 + bit_depth_chroma_minus8 \quad (7-3)$$

$$QpBdOffset_C = 6 * (bit_depth_chroma_minus8 + residual_colour_transform_flag) \quad (7-4)$$

When **bit_depth_chroma_minus8** is not present, it shall be inferred to be equal to 0. **bit_depth_chroma_minus8** shall be in the range of 0 to 4, inclusive.

The variable **RawMbBits** is derived as

$$RawMbBits = 256 * BitDepth_Y + 2 * MbWidthC * MbHeightC * BitDepth_C \quad (7-5)$$

qpprime_y_zero_transform_bypass_flag equal to 1 specifies that, when QP'_Y is equal to 0, a transform bypass operation for the transform coefficient decoding process and picture construction process prior to deblocking filter process as specified in subclause 8.5 shall be applied. **qpprime_y_zero_transform_bypass_flag** equal to 0 specifies that the transform coefficient decoding process and picture construction process prior to deblocking filter process shall not use the transform bypass operation. When **qpprime_y_zero_transform_bypass_flag** is not present, it shall be inferred to be equal to 0.

seq_scaling_matrix_present_flag equal to 1 specifies that the flags **seq_scaling_list_present_flag[i]** for $i = 0..7$ are present. **seq_scaling_matrix_present_flag** equal to 0 specifies that these flags are not present and the sequence-level scaling list specified by **Flat_4x4_16** shall be inferred for $i = 0..5$ and the sequence-level scaling list specified by **Flat_8x8_16** shall be inferred for $i = 6..7$. When **seq_scaling_matrix_present_flag** is not present, it shall be inferred to be equal to 0.

The scaling lists **Flat_4x4_16** and **Flat_8x8_16** are specified as follows:

$$\text{Flat_4x4_16}[i] = 16, \quad \text{with } i = 0..15, \quad (7-6)$$

$$\text{Flat_8x8_16}[i] = 16, \quad \text{with } i = 0..63. \quad (7-7)$$

seq_scaling_list_present_flag[i] equal to 1 specifies that the syntax structure for scaling list i is present in the sequence parameter set. **seq_scaling_list_present_flag[i]** equal to 0 specifies that the syntax structure for scaling list i is not present in the sequence parameter set and the scaling list fall-back rule set A specified in Table 7-2 shall be used to infer the sequence-level scaling list for index i .

Table 7-2 – Assignment of mnemonic names to scaling list indices and specification of fall-back rule

Value of scaling list index	Mnemonic name	Block size	MB prediction type	Component	Scaling list fall-back rule set A	Scaling list fall-back rule set B	Default scaling list
0	SI_4x4_Intra_Y	4x4	Intra	Y	default scaling list	sequence-level scaling list	Default_4x4_Intra
1	SI_4x4_Intra_Cb	4x4	Intra	Cb	scaling list for $i = 0$	scaling list for $i = 0$	Default_4x4_Intra
2	SI_4x4_Intra_Cr	4x4	Intra	Cr	scaling list for $i = 1$	scaling list for $i = 1$	Default_4x4_Intra
3	SI_4x4_Inter_Y	4x4	Inter	Y	default scaling list	sequence-level scaling list	Default_4x4_Inter
4	SI_4x4_Inter_Cb	4x4	Inter	Cb	scaling list for $i = 3$	scaling list for $i = 3$	Default_4x4_Inter
5	SI_4x4_Inter_Cr	4x4	Inter	Cr	scaling list for $i = 4$	scaling list for $i = 4$	Default_4x4_Inter

log2_max_frame_num_minus4 specifies the value of the variable MaxFrameNum that is used in frame_num related derivations as follows:

$$\text{MaxFrameNum} = 2^{(\text{log2_max_frame_num_minus4} + 4)} \quad (7-8)$$

The value of log2_max_frame_num_minus4 shall be in the range of 0 to 12, inclusive.

pic_order_cnt_type specifies the method to decode picture order count (as specified in subclause 8.2.1). The value of pic_order_cnt_type shall be in the range of 0 to 2, inclusive.

pic_order_cnt_type shall not be equal to 2 in a coded video sequence that contains any of the following

- an access unit containing a non-reference frame followed immediately by an access unit containing a non-reference picture;
- two access units each containing a field with the two fields together forming a complementary non-reference field pair followed immediately by an access unit containing a non-reference picture;
- an access unit containing a non-reference field followed immediately by an access unit containing another non-reference picture that does not form a complementary non-reference field pair with the first of the two access units.

log2_max_pic_order_cnt_lsb_minus4 specifies the value of the variable `MaxPicOrderCntLsb` that is used in the decoding process for picture order count as specified in subclause 8.2.1 as follows:

$$\text{MaxPicOrderCntLsb} = 2^{(\text{log2_max_pic_order_cnt_lsb_minus4} + 4)} \quad (7-9)$$

The value of `log2_max_pic_order_cnt_lsb_minus4` shall be in the range of 0 to 12, inclusive.

delta_pic_order_always_zero_flag equal to 1 specifies that `delta_pic_order_cnt[0]` and `delta_pic_order_cnt[1]` are not present in the slice headers of the sequence and shall be inferred to be equal to 0. `delta_pic_order_always_zero_flag` equal to 0 specifies that `delta_pic_order_cnt[0]` is present in the slice headers of the sequence and `delta_pic_order_cnt[1]` may be present in the slice headers of the sequence.

offset_for_non_ref_pic is used to calculate the picture order count of a non-reference picture as specified in 8.2.1. The value of `offset_for_non_ref_pic` shall be in the range of -2^{31} to $2^{31} - 1$, inclusive.

offset_for_top_to_bottom_field is used to calculate the picture order count of a bottom field as specified in subclause 8.2.1. The value of `offset_for_top_to_bottom_field` shall be in the range of -2^{31} to $2^{31} - 1$, inclusive.

num_ref_frames_in_pic_order_cnt_cycle is used in the decoding process for picture order count as specified in subclause 8.2.1. The value of `num_ref_frames_in_pic_order_cnt_cycle` shall be in the range of 0 to 255, inclusive.

offset_for_ref_frame[i] is an element of a list of `num_ref_frames_in_pic_order_cnt_cycle` values used in the decoding process for picture order count as specified in subclause 8.2.1. The value of `offset_for_ref_frame[i]` shall be in the range of -2^{31} to $2^{31} - 1$, inclusive.

num_ref_frames specifies the maximum number of short-term and long-term reference frames, complementary reference field pairs, and non-paired reference fields that may be used by the decoding process for inter prediction of any picture in the sequence. `num_ref_frames` also determines the size of the sliding window operation as specified in subclause 8.2.5.3. The value of `num_ref_frames` shall be in the range of 0 to `MaxDpbSize` (as specified in subclause A.3.1 or A.3.2), inclusive.

gaps_in_frame_num_value_allowed_flag specifies the allowed values of `frame_num` as specified in subclause 7.4.3 and the decoding process in case of an inferred gap between values of `frame_num` as specified in subclause 8.2.5.2.

pic_width_in_mbs_minus1 plus 1 specifies the width of each decoded picture in units of macroblocks.

The variable for the picture width in units of macroblocks is derived as follows

$$\text{PicWidthInMbs} = \text{pic_width_in_mbs_minus1} + 1 \quad (7-10)$$

The variable for picture width for the luma component is derived as follows

$$\text{PicWidthInSamples}_L = \text{PicWidthInMbs} * 16 \quad (7-11)$$

The variable for picture width for the chroma components is derived as follows

$$\text{PicWidthInSamples}_C = \text{PicWidthInMbs} * \text{MbWidthC} \quad (7-12)$$

pic_height_in_map_units_minus1 plus 1 specifies the height in slice group map units of a decoded frame or field.

The variables `PicHeightInMapUnits` and `PicSizeInMapUnits` are derived as follows

$$\text{PicHeightInMapUnits} = \text{pic_height_in_map_units_minus1} + 1 \quad (7-13)$$

$$\text{PicSizeInMapUnits} = \text{PicWidthInMbs} * \text{PicHeightInMapUnits} \quad (7-14)$$

frame_mbs_only_flag equal to 0 specifies that coded pictures of the coded video sequence may either be coded fields or coded frames. `frame_mbs_only_flag` equal to 1 specifies that every coded picture of the coded video sequence is a coded frame containing only frame macroblocks.

The allowed range of values for `pic_width_in_mbs_minus1`, `pic_height_in_map_units_minus1`, and `frame_mbs_only_flag` is specified by constraints in Annex A.

Depending on `frame_mbs_only_flag`, semantics are assigned to `pic_height_in_map_units_minus1` as follows.

- If `frame_mbs_only_flag` is equal to 0, `pic_height_in_map_units_minus1` plus 1 is the height of a field in units of macroblocks.
- Otherwise (`frame_mbs_only_flag` is equal to 1), `pic_height_in_map_units_minus1` plus 1 is the height of a frame in units of macroblocks.

The variable `FrameHeightInMbs` is derived as follows

$$\text{FrameHeightInMbs} = (2 - \text{frame_mbs_only_flag}) * \text{PicHeightInMapUnits} \quad (7-15)$$

`mb_adaptive_frame_field_flag` equal to 0 specifies no switching between frame and field macroblocks within a picture. `mb_adaptive_frame_field_flag` equal to 1 specifies the possible use of switching between frame and field macroblocks within frames. When `mb_adaptive_frame_field_flag` is not present, it shall be inferred to be equal to 0.

`direct_8x8_inference_flag` specifies the method used in the derivation process for luma motion vectors for `B_Skip`, `B_Direct_16x16` and `B_Direct_8x8` as specified in subclause 8.4.1.2. When `frame_mbs_only_flag` is equal to 0, `direct_8x8_inference_flag` shall be equal to 1.

`frame_cropping_flag` equal to 1 specifies that the frame cropping offset parameters follow next in the sequence parameter set. `frame_cropping_flag` equal to 0 specifies that the frame cropping offset parameters are not present.

`frame_crop_left_offset`, `frame_crop_right_offset`, `frame_crop_top_offset`, `frame_crop_bottom_offset` specify the samples of the pictures in the coded video sequence that are output from the decoding process, in terms of a rectangular region specified in frame coordinates for output.

The variables `CropUnitX` and `CropUnitY` are derived as follows:

- If `chroma_format_idc` is equal to 0, `CropUnitX` and `CropUnitY` are derived as

$$\text{CropUnitX} = 1 \quad (7-16)$$

$$\text{CropUnitY} = 2 - \text{frame_mbs_only_flag} \quad (7-17)$$

- Otherwise (`chroma_format_idc` is equal to 1, 2, or 3), `CropUnitX` and `CropUnitY` are derived as

$$\text{CropUnitX} = \text{SubWidthC} \quad (7-18)$$

$$\text{CropUnitY} = \text{SubHeightC} * (2 - \text{frame_mbs_only_flag}) \quad (7-19)$$

The frame cropping rectangle contains luma samples with horizontal frame coordinates from `CropUnitX * frame_crop_left_offset` to `PicWidthInSamplesL - (CropUnitX * frame_crop_right_offset + 1)` and vertical frame coordinates from `CropUnitY * frame_crop_top_offset` to `(16 * FrameHeightInMbs) - (CropUnitY * frame_crop_bottom_offset + 1)`, inclusive. The value of `frame_crop_left_offset` shall be in the range of 0 to `(PicWidthInSamplesL / CropUnitX) - (frame_crop_right_offset + 1)`, inclusive; and the value of `frame_crop_top_offset` shall be in the range of 0 to `(16 * FrameHeightInMbs / CropUnitY) - (frame_crop_bottom_offset + 1)`, inclusive.

When `frame_cropping_flag` is equal to 0, the values of `frame_crop_left_offset`, `frame_crop_right_offset`, `frame_crop_top_offset`, and `frame_crop_bottom_offset` shall be inferred to be equal to 0.

When `chroma_format_idc` is not equal to 0, the corresponding specified samples of the two chroma arrays are the samples having frame coordinates `(x / SubWidthC, y / SubHeightC)`, where `(x, y)` are the frame coordinates of the specified luma samples.

For decoded fields, the specified samples of the decoded field are the samples that fall within the rectangle specified in frame coordinates.

`vui_parameters_present_flag` equal to 1 specifies that the `vui_parameters()` syntax structure as specified in Annex E is present. `vui_parameters_present_flag` equal to 0 specifies that the `vui_parameters()` syntax structure as specified in Annex E is not present.

7.4.2.1.1 Scaling list semantics

`delta_scale` is used to derive the `j`-th element of the scaling list for `j` in the range of 0 to `sizeOfScalingList - 1`, inclusive. The value of `delta_scale` shall be in the range of -128 to +127, inclusive.

When `useDefaultScalingMatrixFlag` is derived to be equal to 1, the scaling list shall be inferred to be equal to the default scaling list as specified in Table 7-2.

7.4.2.1.2 Sequence parameter set extension RBSP semantics

seq_parameter_set_id identifies the sequence parameter set associated with the sequence parameter set extension. The value of seq_parameter_set_id shall be in the range of 0 to 31, inclusive.

aux_format_idc equal to 0 indicates that there are no auxiliary coded pictures in the coded video sequence. aux_format_idc equal to 1 indicates that exactly one auxiliary coded picture is present in each access unit of the coded video sequence, and that for alpha blending purposes the decoded samples of the associated primary coded picture in each access unit should be multiplied by the interpretation sample values of the auxiliary coded picture in the access unit in the display process after output from the decoding process. aux_format_idc equal to 2 indicates that exactly one auxiliary coded picture exists in each access unit of the coded video sequence, and that for alpha blending purposes the decoded samples of the associated primary coded picture in each access unit should not be multiplied by the interpretation sample values of the auxiliary coded picture in the access unit in the display process after output from the decoding process. aux_format_idc equal to 3 indicates that exactly one auxiliary coded picture exists in each access unit of the coded video sequence, and that the usage of the auxiliary coded pictures is unspecified. The value of aux_format_idc shall be in the range of 0 to 3, inclusive. Values greater than 3 for aux_format_idc are reserved to indicate the presence of exactly one auxiliary coded picture in each access unit of the coded video sequence for purposes to be specified in the future by ITU-T | ISO/IEC. When aux_format_idc is not present, it shall be inferred to be equal to 0.

NOTE 1 – Decoders conforming to this Recommendation | International Standard are not required to decode auxiliary coded pictures.

bit_depth_aux_minus8 specifies the bit depth of the samples of the sample array of the auxiliary coded picture. bit_depth_aux_minus8 shall be in the range of 0 to 4, inclusive.

alpha_incr_flag equal to 0 indicates that the interpretation sample value for each decoded auxiliary coded picture sample value is equal to the decoded auxiliary coded picture sample value for purposes of alpha blending. alpha_incr_flag equal to 1 indicates that, for purposes of alpha blending, after decoding the auxiliary coded picture samples, any auxiliary coded picture sample value that is greater than $\text{Min}(\text{alpha_opaque_value}, \text{alpha_transparent_value})$ should be increased by one to obtain the interpretation sample value for the auxiliary coded picture sample, and any auxiliary coded picture sample value that is less than or equal to $\text{Min}(\text{alpha_opaque_value}, \text{alpha_transparent_value})$ should be used without alteration as the interpretation sample value for the decoded auxiliary coded picture sample value.

alpha_opaque_value specifies the interpretation sample value of an auxiliary coded picture sample for which the associated luma and chroma samples of the same access unit are considered opaque for purposes of alpha blending. The number of bits used for the representation of the alpha_opaque_value syntax element is bit_depth_aux_minus8 + 9 bits.

alpha_transparent_value specifies the interpretation sample value of an auxiliary coded picture sample for which the associated luma and chroma samples of the same access unit are considered transparent for purposes of alpha blending. The number of bits used for the representation of the alpha_transparent_value syntax element is bit_depth_aux_minus8 + 9 bits.

When alpha_incr_flag is equal to 1, alpha_transparent_value shall not be equal to alpha_opaque_value and $\text{Log2}(\text{Abs}(\text{alpha_opaque_value} - \text{alpha_transparent_value}))$ shall have an integer value. A value of alpha_transparent_value that is equal to alpha_opaque_value indicates that the auxiliary coded picture is not intended for alpha blending purposes.

NOTE 2 – For alpha blending purposes, alpha_opaque_value may be greater than alpha_transparent_value, or it may be less than alpha_transparent_value. Interpretation sample values should be clipped to the range of alpha_opaque_value to alpha_transparent_value, inclusive.

The decoding of the sequence parameter set extension and the decoding of auxiliary coded pictures is not required for conformance with this Recommendation | International Standard.

The syntax of each coded slice of an auxiliary coded picture shall obey the same constraints as a coded slice of a redundant picture, with the following differences of constraints.

- The following applies in regard to whether the primary coded picture is an IDR picture.
 - If the primary coded picture is an IDR picture, the auxiliary coded slice syntax shall correspond to that of a slice having nal_unit_type equal to 5 (a slice of an IDR picture);
 - Otherwise (the primary coded picture is not an IDR picture), the auxiliary coded slice syntax shall correspond to that of a slice having nal_unit_type equal to 1 (a slice of a non-IDR picture).
- The slices of an auxiliary coded picture (when present) shall contain all macroblocks corresponding to those of the primary coded picture.
- redundant_pic_cnt shall be equal to 0 in all auxiliary coded slices.

The (optional) decoding process for the decoding of auxiliary coded pictures is the same as if the auxiliary coded pictures were primary coded pictures in a separate coded video stream that differs from the primary coded pictures in the current coded video stream in the following ways.

- The IDR or non-IDR status of each auxiliary coded picture shall be inferred to be the same as the IDR or non-IDR status of the primary picture in the same access unit, rather than being inferred from the value of `nal_ref_idc`.
- The value of `chroma_format_idc` shall be inferred to be equal to 0 for the decoding of the auxiliary coded pictures.
- The value of `bit_depth_luma_minus8` shall be inferred to be equal to `bit_depth_aux_minus8` for the decoding of the auxiliary coded pictures.

NOTE 3 – Alpha blending composition is normally performed with a background picture B, a foreground picture F, and a decoded auxiliary coded picture A, all of the same size. Assume for purposes of example illustration that the chroma resolution of B and F have been upsampled to the same resolution as the luma. Denote corresponding samples of B, F and A by b , f and a , respectively. Denote luma and chroma samples by subscripts Y, Cb and Cr.

Define the variables `alphaRange`, `alphaFwt` and `alphaBwt` as follows:

$$\text{alphaRange} = \text{Abs}(\text{alpha_opaque_value} - \text{alpha_transparent_value})$$

$$\text{alphaFwt} = \text{Abs}(a - \text{alpha_transparent_value})$$

$$\text{alphaBwt} = \text{Abs}(a - \text{alpha_opaque_value})$$

Then, in alpha blending composition, samples d of the displayed picture D may be calculated as

$$d_Y = (\text{alphaFwt} * f_Y + \text{alphaBwt} * b_Y + \text{alphaRange}/2) / \text{alphaRange}$$

$$d_{CB} = (\text{alphaFwt} * f_{CB} + \text{alphaBwt} * b_{CB} + \text{alphaRange}/2) / \text{alphaRange}$$

$$d_{CR} = (\text{alphaFwt} * f_{CR} + \text{alphaBwt} * b_{CR} + \text{alphaRange}/2) / \text{alphaRange}$$

The samples of pictures D, F and B could also represent red, green, and blue component values (see subclause E.2.1). Here we have assumed Y, Cb and Cr component values. Each component, e.g. Y, is assumed for purposes of example illustration above to have the same bit depth in each of the pictures D, F and B. However, different components, e.g. Y and Cb, need not have the same bit depth in this example.

When `aux_format_idc` is equal to 1, F would be the decoded picture obtained from the decoded luma and chroma, and A would be the decoded picture obtained from the decoded auxiliary coded picture. In this case, the indicated example alpha blending composition involves multiplying the samples of F by factors obtained from the samples of A.

A picture format that is useful for editing or direct viewing, and that is commonly used, is called pre-multiplied-black video. If the foreground picture was F, then the pre-multiplied-black video S is given by

$$s_Y = (\text{alphaFwt} * f_Y) / \text{alphaRange}$$

$$s_{CB} = (\text{alphaFwt} * f_{CB}) / \text{alphaRange}$$

$$s_{CR} = (\text{alphaFwt} * f_{CR}) / \text{alphaRange}$$

Pre-multiplied-black video has the characteristic that the picture S will appear correct if displayed against a black background. For a non-black background B, the composition of the displayed picture D may be calculated as

$$d_Y = s_Y + (\text{alphaBwt} * b_Y + \text{alphaRange}/2) / \text{alphaRange}$$

$$d_{CB} = s_{CB} + (\text{alphaBwt} * b_{CB} + \text{alphaRange}/2) / \text{alphaRange}$$

$$d_{CR} = s_{CR} + (\text{alphaBwt} * b_{CR} + \text{alphaRange}/2) / \text{alphaRange}$$

When `aux_format_idc` is equal to 2, S would be the decoded picture obtained from the decoded luma and chroma, and A would again be the decoded picture obtained from the decoded auxiliary coded picture. In this case, alpha blending composition does not involve multiplication of the samples of S by factors obtained from the samples of A.

additional_extension_flag equal to 0 indicates that no additional data follows within the sequence parameter set extension syntax structure prior to the Rbsp trailing bits. The value of `additional_extension_flag` shall be equal to 0. The value of 1 for `additional_extension_flag` is reserved for future use by ITU-T | ISO/IEC. Decoders that conform to this Recommendation | International Standard shall ignore all data that follows the value of 1 for `additional_extension_flag` in a sequence parameter set extension NAL unit.

7.4.2.2 Picture parameter set Rbsp semantics

pic_parameter_set_id identifies the picture parameter set that is referred to in the slice header. The value of `pic_parameter_set_id` shall be in the range of 0 to 255, inclusive.

seq_parameter_set_id refers to the active sequence parameter set. The value of `seq_parameter_set_id` shall be in the range of 0 to 31, inclusive.

entropy_coding_mode_flag selects the entropy decoding method to be applied for the syntax elements for which two descriptors appear in the syntax tables as follows.

- If `entropy_coding_mode_flag` is equal to 0, the method specified by the left descriptor in the syntax table is applied (Exp-Golomb coded, see subclause 9.1 or CAVLC, see subclause 9.2).
- Otherwise (`entropy_coding_mode_flag` is equal to 1), the method specified by the right descriptor in the syntax table is applied (CABAC, see subclause 9.3).

pic_order_present_flag equal to 1 specifies that the picture order count related syntax elements are present in the slice headers as specified in subclause 7.3.3. **pic_order_present_flag** equal to 0 specifies that the picture order count related syntax elements are not present in the slice headers.

num_slice_groups_minus1 plus 1 specifies the number of slice groups for a picture. When **num_slice_groups_minus1** is equal to 0, all slices of the picture belong to the same slice group. The allowed range of **num_slice_groups_minus1** is specified in Annex A.

slice_group_map_type specifies how the mapping of slice group map units to slice groups is coded. The value of **slice_group_map_type** shall be in the range of 0 to 6, inclusive.

slice_group_map_type equal to 0 specifies interleaved slice groups.

slice_group_map_type equal to 1 specifies a dispersed slice group mapping.

slice_group_map_type equal to 2 specifies one or more “foreground” slice groups and a “leftover” slice group.

slice_group_map_type values equal to 3, 4, and 5 specify changing slice groups. When **num_slice_groups_minus1** is not equal to 1, **slice_group_map_type** shall not be equal to 3, 4, or 5.

slice_group_map_type equal to 6 specifies an explicit assignment of a slice group to each slice group map unit.

Slice group map units are specified as follows.

- If **frame_mbs_only_flag** is equal to 0 and **mb_adaptive_frame_field_flag** is equal to 1 and the coded picture is a frame, the slice group map units are macroblock pair units.
- Otherwise, if **frame_mbs_only_flag** is equal to 1 or a coded picture is a field, the slice group map units are units of macroblocks.
- Otherwise (**frame_mbs_only_flag** is equal to 0 and **mb_adaptive_frame_field_flag** is equal to 0 and the coded picture is a frame), the slice group map units are units of two macroblocks that are vertically contiguous as in a frame macroblock pair of an MBAFF frame.

run_length_minus1[i] is used to specify the number of consecutive slice group map units to be assigned to the *i*-th slice group in raster scan order of slice group map units. The value of **run_length_minus1[i]** shall be in the range of 0 to **PicSizeInMapUnits** - 1, inclusive.

top_left[i] and **bottom_right[i]** specify the top-left and bottom-right corners of a rectangle, respectively. **top_left[i]** and **bottom_right[i]** are slice group map unit positions in a raster scan of the picture for the slice group map units. For each rectangle *i*, all of the following constraints shall be obeyed by the values of the syntax elements **top_left[i]** and **bottom_right[i]**

- **top_left[i]** shall be less than or equal to **bottom_right[i]** and **bottom_right[i]** shall be less than **PicSizeInMapUnits**.
- (**top_left[i]** % **PicWidthInMbs**) shall be less than or equal to the value of (**bottom_right[i]** % **PicWidthInMbs**).

slice_group_change_direction_flag is used with **slice_group_map_type** to specify the refined map type when **slice_group_map_type** is 3, 4, or 5.

slice_group_change_rate_minus1 is used to specify the variable **SliceGroupChangeRate**. **SliceGroupChangeRate** specifies the multiple in number of slice group map units by which the size of a slice group can change from one picture to the next. The value of **slice_group_change_rate_minus1** shall be in the range of 0 to **PicSizeInMapUnits** - 1, inclusive. The **SliceGroupChangeRate** variable is specified as follows:

$$\text{SliceGroupChangeRate} = \text{slice_group_change_rate_minus1} + 1 \quad (7-20)$$

pic_size_in_map_units_minus1 is used to specify the number of slice group map units in the picture. **pic_size_in_map_units_minus1** shall be equal to **PicSizeInMapUnits** - 1.

slice_group_id[i] identifies a slice group of the *i*-th slice group map unit in raster scan order. The size of the **slice_group_id[i]** syntax element is $\text{Ceil}(\text{Log2}(\text{num_slice_groups_minus1} + 1))$ bits. The value of **slice_group_id[i]** shall be in the range of 0 to **num_slice_groups_minus1**, inclusive.

num_ref_idx_l0_active_minus1 specifies the maximum reference index for reference picture list 0 that shall be used to decode each slice of the picture in which list 0 prediction is used when **num_ref_idx_active_override_flag** is equal to 0 for the slice. When **MbaffFrameFlag** is equal to 1, **num_ref_idx_l0_active_minus1** is the maximum index value for the decoding of frame macroblocks and $2 * \text{num_ref_idx_l0_active_minus1} + 1$ is the maximum index value for the decoding of field macroblocks. The value of **num_ref_idx_l0_active_minus1** shall be in the range of 0 to 31, inclusive.

num_ref_idx_l1_active_minus1 has the same semantics as num_ref_idx_l0_active_minus1 with l0 and list 0 replaced by l1 and list 1, respectively.

weighted_pred_flag equal to 0 specifies that weighted prediction shall not be applied to P and SP slices. weighted_pred_flag equal to 1 specifies that weighted prediction shall be applied to P and SP slices.

weighted_bipred_idc equal to 0 specifies that the default weighted prediction shall be applied to B slices. weighted_bipred_idc equal to 1 specifies that explicit weighted prediction shall be applied to B slices. weighted_bipred_idc equal to 2 specifies that implicit weighted prediction shall be applied to B slices. The value of weighted_bipred_idc shall be in the range of 0 to 2, inclusive.

pic_init_qp_minus26 specifies the initial value minus 26 of SliceQP_Y for each slice. The initial value is modified at the slice layer when a non-zero value of slice_qp_delta is decoded, and is modified further when a non-zero value of mb_qp_delta is decoded at the macroblock layer. The value of pic_init_qp_minus26 shall be in the range of $-(26 + QpBdOffset_Y)$ to +25, inclusive.

pic_init_qs_minus26 specifies the initial value minus 26 of SliceQS_Y for all macroblocks in SP or SI slices. The initial value is modified at the slice layer when a non-zero value of slice_qs_delta is decoded. The value of pic_init_qs_minus26 shall be in the range of -26 to +25, inclusive.

chroma_qp_index_offset specifies the offset that shall be added to QP_Y and QS_Y for addressing the table of QP_C values for the Cb chroma component. The value of chroma_qp_index_offset shall be in the range of -12 to +12, inclusive.

deblocking_filter_control_present_flag equal to 1 specifies that a set of syntax elements controlling the characteristics of the deblocking filter is present in the slice header. deblocking_filter_control_present_flag equal to 0 specifies that the set of syntax elements controlling the characteristics of the deblocking filter is not present in the slice headers and their inferred values are in effect.

constrained_intra_pred_flag equal to 0 specifies that intra prediction allows usage of residual data and decoded samples of neighbouring macroblocks coded using Inter macroblock prediction modes for the prediction of macroblocks coded using Intra macroblock prediction modes. constrained_intra_pred_flag equal to 1 specifies constrained intra prediction, in which case prediction of macroblocks coded using Intra macroblock prediction modes only uses residual data and decoded samples from I or SI macroblock types.

redundant_pic_cnt_present_flag equal to 0 specifies that the redundant_pic_cnt syntax element is not present in slice headers, data partitions B, and data partitions C that refer (either directly or by association with a corresponding data partition A) to the picture parameter set. redundant_pic_cnt_present_flag equal to 1 specifies that the redundant_pic_cnt syntax element is present in all slice headers, data partitions B, and data partitions C that refer (either directly or by association with a corresponding data partition A) to the picture parameter set.

transform_8x8_mode_flag equal to 1 specifies that the 8x8 transform decoding process may be in use (see subclause 8.5). transform_8x8_mode_flag equal to 0 specifies that the 8x8 transform decoding process is not in use. When transform_8x8_mode_flag is not present, it shall be inferred to be 0.

pic_scaling_matrix_present_flag equal to 1 specifies that parameters are present to modify the scaling lists specified in the sequence parameter set. pic_scaling_matrix_present_flag equal to 0 specifies that the scaling lists used for the picture shall be inferred to be equal to those specified by the sequence parameter set. When pic_scaling_matrix_present_flag is not present, it shall be inferred to be equal to 0.

pic_scaling_list_present_flag[i] equal to 1 specifies that the scaling list syntax structure is present to specify the scaling list for index i. pic_scaling_list_present_flag[i] equal to 0 specifies that the syntax structure for scaling list i is not present in the picture parameter set and that depending on the value of seq_scaling_matrix_present_flag, the following applies.

- If seq_scaling_matrix_present_flag is equal to 0, the scaling list fall-back rule set A as specified in Table 7-2 shall be used to derive the picture-level scaling list for index i.
- Otherwise (seq_scaling_matrix_present_flag is equal to 1), the scaling list fall-back rule set B as specified in Table 7-2 shall be used to derive the picture-level scaling list for index i.

second_chroma_qp_index_offset specifies the offset that shall be added to QP_Y and QS_Y for addressing the table of QP_C values for the Cr chroma component. The value of second_chroma_qp_index_offset shall be in the range of -12 to +12, inclusive.

When second_chroma_qp_index_offset is not present, it shall be inferred to be equal to chroma_qp_index_offset.

7.4.2.3 Supplemental enhancement information RBSP semantics

Supplemental Enhancement Information (SEI) contains information that is not necessary to decode the samples of coded pictures from VCL NAL units.

7.4.2.3.1 Supplemental enhancement information message semantics

An SEI NAL unit contains one or more SEI messages. Each SEI message consists of the variables specifying the type payloadType and size payloadSize of the SEI payload. SEI payloads are specified in Annex D. The derived SEI payload size payloadSize is specified in bytes and shall be equal to the number of bytes in the SEI payload.

ff_byte is a byte equal to 0xFF identifying a need for a longer representation of the syntax structure that it is used within.

last_payload_type_byte is the last byte of the payload type of an SEI message.

last_payload_size_byte is the last byte of the size of an SEI message.

7.4.2.4 Access unit delimiter RBSP semantics

The access unit delimiter may be used to indicate the type of slices present in a primary coded picture and to simplify the detection of the boundary between access units. There is no normative decoding process associated with the access unit delimiter.

primary_pic_type indicates that the slice_type values for all slices of the primary coded picture are members of the set listed in Table 7-5 for the given value of primary_pic_type.

Table 7-5 – Meaning of primary_pic_type

primary_pic_type	slice_type values that may be present in the primary coded picture
0	I
1	I, P
2	I, P, B
3	SI
4	SI, SP
5	I, SI
6	I, SI, P, SP
7	I, SI, P, SP, B

7.4.2.5 End of sequence RBSP semantics

The end of sequence RBSP specifies that the next subsequent access unit in the bitstream in decoding order (if any) shall be an IDR access unit. The syntax content of the SODB and RBSP for the end of sequence RBSP are empty. No normative decoding process is specified for an end of sequence RBSP.

7.4.2.6 End of stream RBSP semantics

The end of stream RBSP indicates that no additional NAL units shall be present in the bitstream that are subsequent to the end of stream RBSP in decoding order. The syntax content of the SODB and RBSP for the end of stream RBSP are empty. No normative decoding process is specified for an end of stream RBSP.

7.4.2.7 Filler data RBSP semantics

The filler data RBSP contains bytes whose value shall be equal to 0xFF. No normative decoding process is specified for a filler data RBSP.

ff_byte is a byte equal to 0xFF.

7.4.2.8 Slice layer without partitioning RBSP semantics

The slice layer without partitioning RBSP consists of a slice header and slice data.

7.4.2.9 Slice data partition RBSP semantics

7.4.2.9.1 Slice data partition A RBSP semantics

When slice data partitioning is in use, the coded data for a single slice is divided into three separate partitions. Partition A contains all syntax elements of category 2.

Category 2 syntax elements include all syntax elements in the slice header and slice data syntax structures other than the syntax elements in the residual() syntax structure.

slice_id identifies the slice associated with the data partition. Each slice shall have a unique slice_id value within the coded picture that contains the slice. When arbitrary slice order is not allowed as specified in Annex A, the first slice of a coded picture, in decoding order, shall have slice_id equal to 0 and the value of slice_id shall be incremented by one for each subsequent slice of the coded picture in decoding order.

The range of slice_id is specified as follows.

- If MbaffFrameFlag is equal to 0, slice_id shall be in the range of 0 to PicSizeInMbs - 1, inclusive.
- Otherwise (MbaffFrameFlag is equal to 1), slice_id shall be in the range of 0 to PicSizeInMbs / 2 - 1, inclusive.

7.4.2.9.2 Slice data partition B RBSP semantics

When slice data partitioning is in use, the coded data for a single slice is divided into one to three separate partitions. Slice data partition B contains all syntax elements of category 3.

Category 3 syntax elements include all syntax elements in the residual() syntax structure and in syntax structures used within that syntax structure for collective macroblock types I and SI as specified in Table 7-10.

slice_id has the same semantics as specified in subclause 7.4.2.9.1.

redundant_pic_cnt shall be equal to 0 for slices and slice data partitions belonging to the primary coded picture. The redundant_pic_cnt shall be greater than 0 for coded slices and coded slice data partitions in redundant coded pictures. When redundant_pic_cnt is not present, its value shall be inferred to be equal to 0. The value of redundant_pic_cnt shall be in the range of 0 to 127, inclusive.

The presence of a slice data partition B RBSP is specified as follows.

- If the syntax elements of a slice data partition A RBSP indicate the presence of any syntax elements of category 3 in the slice data for a slice, a slice data partition B RBSP shall be present having the same value of slice_id and redundant_pic_cnt as in the slice data partition A RBSP.
- Otherwise (the syntax elements of a slice data partition A RBSP do not indicate the presence of any syntax elements of category 3 in the slice data for a slice), no slice data partition B RBSP shall be present having the same value of slice_id and redundant_pic_cnt as in the slice data partition A RBSP.

7.4.2.9.3 Slice data partition C RBSP semantics

When slice data partitioning is in use, the coded data for a single slice is divided into three separate partitions. Slice data partition C contains all syntax elements of category 4.

Category 4 syntax elements include all syntax elements in the residual() syntax structure and in syntax structures used within that syntax structure for collective macroblock types P and B as specified in Table 7-10.

slice_id has the same semantics as specified in subclause 7.4.2.9.1.

redundant_pic_cnt has the same semantics as specified in subclause 7.4.2.9.2.

The presence of a slice data partition C RBSP is specified as follows.

- If the syntax elements of a slice data partition A RBSP indicate the presence of any syntax elements of category 4 in the slice data for a slice, a slice data partition C RBSP shall be present having the same value of slice_id and redundant_pic_cnt as in the slice data partition A RBSP.
- Otherwise (the syntax elements of a slice data partition A RBSP do not indicate the presence of any syntax elements of category 4 in the slice data for a slice), no slice data partition C RBSP shall be present having the same value of slice_id and redundant_pic_cnt as in the slice data partition A RBSP.

7.4.2.10 RBSP slice trailing bits semantics

cabac_zero_word is a byte-aligned sequence of two bytes equal to 0x0000.

Let NumBytesInVclNALunits be the sum of the values of NumBytesInNALunit for all VCL NAL units of a coded picture.

Let BinCountsInNALunits be the number of times that the parsing process function DecodeBin(), specified in subclause 9.3.3.2, is invoked to decode the contents of all VCL NAL units of a coded picture. When entropy_coding_mode_flag is equal to 1, BinCountsInNALunits shall not exceed $(32 \div 3) * \text{NumBytesInVclNALunits} + (\text{RawMbBits} * \text{PicSizeInMbs}) \div 32$.

NOTE – The constraint on the maximum number of bins resulting from decoding the contents of the slice layer NAL units can be met by inserting a number of cabac_zero_word syntax elements to increase the value of NumBytesInVclNALunits. Each cabac_zero_word is represented in a NAL unit by the three-byte sequence 0x000003 (as a result of the constraints on NAL unit contents that result in requiring inclusion of an emulation_prevention_three_byte for each cabac_zero_word).

7.4.2.11 RBSP trailing bits semantics

rbsp_stop_one_bit shall be equal to 1.

rbsp_alignment_zero_bit shall be equal to 0.

7.4.3 Slice header semantics

When present, the value of the slice header syntax elements pic_parameter_set_id, frame_num, field_pic_flag, bottom_field_flag, idr_pic_id, pic_order_cnt_lsb, delta_pic_order_cnt_bottom, delta_pic_order_cnt[0], delta_pic_order_cnt[1], sp_for_switch_flag, and slice_group_change_cycle shall be the same in all slice headers of a coded picture.

first_mb_in_slice specifies the address of the first macroblock in the slice. When arbitrary slice order is not allowed as specified in Annex A, the value of first_mb_in_slice shall not be less than the value of first_mb_in_slice for any other slice of the current picture that precedes the current slice in decoding order.

The first macroblock address of the slice is derived as follows.

- If MbaffFrameFlag is equal to 0, first_mb_in_slice is the macroblock address of the first macroblock in the slice, and first_mb_in_slice shall be in the range of 0 to PicSizeInMbs - 1, inclusive.
- Otherwise (MbaffFrameFlag is equal to 1), first_mb_in_slice * 2 is the macroblock address of the first macroblock in the slice, which is the top macroblock of the first macroblock pair in the slice, and first_mb_in_slice shall be in the range of 0 to PicSizeInMbs / 2 - 1, inclusive.

slice_type specifies the coding type of the slice according to Table 7-6.

Table 7-6 – Name association to slice_type

slice_type	Name of slice_type
0	P (P slice)
1	B (B slice)
2	I (I slice)
3	SP (SP slice)
4	SI (SI slice)
5	P (P slice)
6	B (B slice)
7	I (I slice)
8	SP (SP slice)
9	SI (SI slice)

slice_type values in the range 5..9 specify, in addition to the coding type of the current slice, that all other slices of the current coded picture shall have a value of slice_type equal to the current value of slice_type or equal to the current value of slice_type - 5.

When nal_unit_type is equal to 5 (IDR picture), slice_type shall be equal to 2, 4, 7, or 9.

When num_ref_frames is equal to 0, slice_type shall be equal to 2, 4, 7, or 9.

pic_parameter_set_id specifies the picture parameter set in use. The value of pic_parameter_set_id shall be in the range of 0 to 255, inclusive.

frame_num is used as an identifier for pictures and shall be represented by $\log_2 \text{max_frame_num_minus4} + 4$ bits in the bitstream. **frame_num** is constrained as follows:

The variable **PrevRefFrameNum** is derived as follows.

- If the current picture is an IDR picture, **PrevRefFrameNum** is set equal to 0.
- Otherwise (the current picture is not an IDR picture), **PrevRefFrameNum** is set as follows.
 - If the decoding process for gaps in **frame_num** specified in subclause 8.2.5.2 was invoked by the decoding process for an access unit that contained a non-reference picture that followed the previous access unit in decoding order that contained a reference picture, **PrevRefFrameNum** is set equal to the value of **frame_num** for the last of the "non-existing" reference frames inferred by the decoding process for gaps in **frame_num** specified in subclause 8.2.5.2.
 - Otherwise, **PrevRefFrameNum** is set equal to the value of **frame_num** for the previous access unit in decoding order that contained a reference picture.

The value of **frame_num** is constrained as follows.

- If the current picture is an IDR picture, **frame_num** shall be equal to 0.
- Otherwise (the current picture is not an IDR picture), referring to the primary coded picture in the previous access unit in decoding order that contains a reference picture as the preceding reference picture, the value of **frame_num** for the current picture shall not be equal to **PrevRefFrameNum** unless all of the following three conditions are true.
 - the current picture and the preceding reference picture belong to consecutive access units in decoding order
 - the current picture and the preceding reference picture are reference fields having opposite parity
 - one or more of the following conditions is true
 - the preceding reference picture is an IDR picture
 - the preceding reference picture includes a **memory_management_control_operation** syntax element equal to 5
NOTE 1 – When the preceding reference picture includes a **memory_management_control_operation** syntax element equal to 5, **PrevRefFrameNum** is equal to 0.
 - there is a primary coded picture that precedes the preceding reference picture and the primary coded picture that precedes the preceding reference picture does not have **frame_num** equal to **PrevRefFrameNum**
 - there is a primary coded picture that precedes the preceding reference picture and the primary coded picture that precedes the preceding reference picture is not a reference picture

When the value of **frame_num** is not equal to **PrevRefFrameNum**, the following applies.

- There shall not be any previous field or frame in decoding order that is currently marked as "used for short-term reference" that has a value of **frame_num** equal to any value taken on by the variable **UnusedShortTermFrameNum** in the following:

```
UnusedShortTermFrameNum = ( PrevRefFrameNum + 1 ) % MaxFrameNum
while( UnusedShortTermFrameNum != frame_num )
    UnusedShortTermFrameNum = ( UnusedShortTermFrameNum + 1 ) % MaxFrameNum
```

(7-21)

- The value of **frame_num** is constrained as follows.
 - If **gaps_in_frame_num_value_allowed_flag** is equal to 0, the value of **frame_num** for the current picture shall be equal to $(\text{PrevRefFrameNum} + 1) \% \text{MaxFrameNum}$.
 - Otherwise (**gaps_in_frame_num_value_allowed_flag** is equal to 1), the following applies.
 - If **frame_num** is greater than **PrevRefFrameNum**, there shall not be any non-reference pictures in the bitstream that follow the previous reference picture and precede the current picture in decoding order in which either of the following conditions is true.
 - The value of **frame_num** for the non-reference picture is less than **PrevRefFrameNum**.
 - The value of **frame_num** for the non-reference picture is greater than the value of **frame_num** for the current picture.

- Otherwise (frame_num is less than PrevRefFrameNum), there shall not be any non-reference pictures in the bitstream that follow the previous reference picture and precede the current picture in decoding order in which both of the following conditions are true.
 - The value of frame_num for the non-reference picture is less than PrevRefFrameNum.
 - The value of frame_num for the non-reference picture is greater than the value of frame_num for the current picture.

A picture including a memory_management_control_operation equal to 5 shall have frame_num constraints as described above and, after the decoding of the current picture and the processing of the memory management control operations, the picture shall be inferred to have had frame_num equal to 0 for all subsequent use in the decoding process, except as specified in subclause 7.4.1.2.4.

NOTE 2 – When the primary coded picture is not an IDR picture and does not contain memory_management_control_operation syntax element equal to 5, the value of frame_num of a corresponding redundant coded picture is the same as the value of frame_num in the primary coded picture. Alternatively, the redundant coded picture includes a memory_management_control_operation syntax element equal to 5 and the corresponding primary coded picture is an IDR picture.

field_pic_flag equal to 1 specifies that the slice is a slice of a coded field. field_pic_flag equal to 0 specifies that the slice is a slice of a coded frame. When field_pic_flag is not present it shall be inferred to be equal to 0.

The variable MbaffFrameFlag is derived as follows.

$$\text{MbaffFrameFlag} = (\text{mb_adaptive_frame_field_flag} \ \&\& \ !\text{field_pic_flag}) \quad (7-22)$$

The variable for the picture height in units of macroblocks is derived as follows

$$\text{PicHeightInMbs} = \text{FrameHeightInMbs} / (1 + \text{field_pic_flag}) \quad (7-23)$$

The variable for picture height for the luma component is derived as follows

$$\text{PicHeightInSamples}_L = \text{PicHeightInMbs} * 16 \quad (7-24)$$

The variable for picture height for the chroma component is derived as follows

$$\text{PicHeightInSamples}_C = \text{PicHeightInMbs} * \text{MbHeightC} \quad (7-25)$$

The variable PicSizeInMbs for the current picture is derived according to:

$$\text{PicSizeInMbs} = \text{PicWidthInMbs} * \text{PicHeightInMbs} \quad (7-26)$$

The variable MaxPicNum is derived as follows.

- If field_pic_flag is equal to 0, MaxPicNum is set equal to MaxFrameNum.
- Otherwise (field_pic_flag is equal to 1), MaxPicNum is set equal to 2*MaxFrameNum.

The variable CurrPicNum is derived as follows.

- If field_pic_flag is equal to 0, CurrPicNum is set equal to frame_num.
- Otherwise (field_pic_flag is equal to 1), CurrPicNum is set equal to 2 * frame_num + 1.

bottom_field_flag equal to 1 specifies that the slice is part of a coded bottom field. bottom_field_flag equal to 0 specifies that the picture is a coded top field. When this syntax element is not present for the current slice, it shall be inferred to be equal to 0.

idr_pic_id identifies an IDR picture. The values of idr_pic_id in all the slices of an IDR picture shall remain unchanged. When two consecutive access units in decoding order are both IDR access units, the value of idr_pic_id in the slices of the first such IDR access unit shall differ from the idr_pic_id in the second such IDR access unit. The value of idr_pic_id shall be in the range of 0 to 65535, inclusive.

pic_order_cnt_lsb specifies the picture order count modulo MaxPicOrderCntLsb for the top field of a coded frame or for a coded field. The size of the pic_order_cnt_lsb syntax element is log2_max_pic_order_cnt_lsb_minus4 + 4 bits. The value of the pic_order_cnt_lsb shall be in the range of 0 to MaxPicOrderCntLsb – 1, inclusive.

delta_pic_order_cnt_bottom specifies the picture order count difference between the bottom field and the top field of a coded frame as follows.

- If the current picture includes a `memory_management_control_operation` equal to 5, the value of `delta_pic_order_cnt_bottom` shall be in the range of $(1 - \text{MaxPicOrderCntLsb})$ to $2^{31} - 1$, inclusive.
- Otherwise (the current picture does not include a `memory_management_control_operation` equal to 5), the value of `delta_pic_order_cnt_bottom` shall be in the range of -2^{31} to $2^{31} - 1$, inclusive.

When this syntax element is not present in the bitstream for the current slice, it shall be inferred to be equal to 0.

delta_pic_order_cnt[0] specifies the picture order count difference from the expected picture order count for the top field of a coded frame or for a coded field as specified in subclause 8.2.1. The value of `delta_pic_order_cnt[0]` shall be in the range of -2^{31} to $2^{31} - 1$, inclusive. When this syntax element is not present in the bitstream for the current slice, it shall be inferred to be equal to 0.

delta_pic_order_cnt[1] specifies the picture order count difference from the expected picture order count for the bottom field of a coded frame specified in subclause 8.2.1. The value of `delta_pic_order_cnt[1]` shall be in the range of -2^{31} to $2^{31} - 1$, inclusive. When this syntax element is not present in the bitstream for the current slice, it shall be inferred to be equal to 0.

redundant_pic_cnt shall be equal to 0 for slices and slice data partitions belonging to the primary coded picture. The value of `redundant_pic_cnt` shall be greater than 0 for coded slices or coded slice data partitions of a redundant coded picture. When `redundant_pic_cnt` is not present in the bitstream, its value shall be inferred to be equal to 0. The value of `redundant_pic_cnt` shall be in the range of 0 to 127, inclusive.

NOTE 3 – Any area of the decoded primary picture and the corresponding area that would result from application of the decoding process specified in clause 8 for any redundant picture in the same access unit should be visually similar in appearance.

The value of `pic_parameter_set_id` in a coded slice or coded slice data partition of a redundant coded picture shall be such that the value of `pic_order_present_flag` in the picture parameter set in use in a redundant coded picture is equal to the value of `pic_order_present_flag` in the picture parameter set in use in the corresponding primary coded picture.

When present in the primary coded picture and any redundant coded picture, the following syntax elements shall have the same value: `field_pic_flag`, `bottom_field_flag`, and `idr_pic_id`.

When the value of `nal_ref_idc` in one VCL NAL unit of an access unit is equal to 0, the value of `nal_ref_idc` in all other VCL NAL units of the same access unit shall be equal to 0.

NOTE 4 – The above constraint also has the following implications. If the value of `nal_ref_idc` for the VCL NAL units of the primary coded picture is equal to 0, the value of `nal_ref_idc` for the VCL NAL units of any corresponding redundant coded picture are equal to 0; otherwise (the value of `nal_ref_idc` for the VCL NAL units of the primary coded picture is greater than 0), the value of `nal_ref_idc` for the VCL NAL units of any corresponding redundant coded picture are also greater than 0.

The marking status of reference pictures and the value of `frame_num` after the decoded reference picture marking process as specified in subclause 8.2.5 is invoked for the primary coded picture or any redundant coded picture of the same access unit shall be identical regardless whether the primary coded picture or any redundant coded picture (instead of the primary coded picture) of the access unit would be decoded.

NOTE 5 – The above constraint also has the following implications.

If a primary coded picture is not an IDR picture, the contents of the `dec_ref_pic_marking()` syntax structure must be identical in all slice headers of the primary coded picture and all redundant coded pictures corresponding to the primary coded picture.

Otherwise (a primary coded picture is an IDR picture), the following applies.

If a redundant coded picture corresponding to the primary coded picture is an IDR picture, the contents of the `dec_ref_pic_marking()` syntax structure must be identical in all slice headers of the primary coded picture and the redundant coded picture corresponding to the primary coded picture.

Otherwise (a redundant picture corresponding to the primary coded picture is not an IDR picture), all slice headers of the redundant picture must contain a `dec_ref_pic_marking` syntax() structure including a `memory_management_control_operation` syntax element equal to 5, and the following applies.

If the value of `long_term_reference_flag` in the primary coded picture is equal to 0, the `dec_ref_pic_marking` syntax structure of the redundant coded picture must not include a `memory_management_control_operation` syntax element equal to 6.

Otherwise (the value of `long_term_reference_flag` in the primary coded picture is equal to 1), the `dec_ref_pic_marking` syntax structure of the redundant coded picture must include `memory_management_control_operation` syntax elements equal to 5, 4, and 6 in decoding order, and the value of `max_long_term_frame_idx_plus1` must be equal to 1, and the value of `long_term_frame_idx` must be equal to 0.

The values of `TopFieldOrderCnt` and `BottomFieldOrderCnt` (if applicable) that result after completion of the decoding process for any redundant coded picture or the primary coded picture of the same access unit shall be identical regardless whether the primary coded picture or any redundant coded picture (instead of the primary coded picture) of the access unit would be decoded.

There is no required decoding process for a coded slice or coded slice data partition of a redundant coded picture. When the `redundant_pic_cnt` in the slice header of a coded slice is greater than 0, the decoder may discard the coded slice. However, a coded slice or coded slice data partition of any redundant coded picture shall obey the same constraints as a coded slice or coded slice data partition of a primary picture.

NOTE 6 – When some of the samples in the decoded primary picture cannot be correctly decoded due to errors or losses in transmission of the sequence and a coded redundant slice can be correctly decoded, the decoder should replace the samples of the decoded primary picture with the corresponding samples of the decoded redundant slice. When more than one redundant slice covers the relevant region of the primary picture, the redundant slice having the lowest value of `redundant_pic_cnt` should be used.

Redundant slices and slice data partitions having the same value of `redundant_pic_cnt` belong to the same redundant picture. Decoded slices within the same redundant picture need not cover the entire picture area and shall not overlap.

direct_spatial_mv_pred_flag specifies the method used in the decoding process to derive motion vectors and reference indices for inter prediction as follows.

- If `direct_spatial_mv_pred_flag` is equal to 1, the derivation process for luma motion vectors for `B_Skip`, `B_Direct_16x16`, and `B_Direct_8x8` in subclause 8.4.1.2 shall use spatial direct mode prediction as specified in subclause 8.4.1.2.2.
- Otherwise (`direct_spatial_mv_pred_flag` is equal to 0), the derivation process for luma motion vectors for `B_Skip`, `B_Direct_16x16`, and `B_Direct_8x8` in subclause 8.4.1.2 shall use temporal direct mode prediction as specified in subclause 8.4.1.2.3.

num_ref_idx_active_override_flag equal to 0 specifies that the values of the syntax elements `num_ref_idx_l0_active_minus1` and `num_ref_idx_l1_active_minus1` specified in the referred picture parameter set are in effect. `num_ref_idx_active_override_flag` equal to 1 specifies that the `num_ref_idx_l0_active_minus1` and `num_ref_idx_l1_active_minus1` specified in the referred picture parameter set are overridden for the current slice (and only for the current slice) by the following values in the slice header.

When the current slice is a P, SP, or B slice and `field_pic_flag` is equal to 0 and the value of `num_ref_idx_l0_active_minus1` in the picture parameter set exceeds 15, `num_ref_idx_active_override_flag` shall be equal to 1.

When the current slice is a B slice and `field_pic_flag` is equal to 0 and the value of `num_ref_idx_l1_active_minus1` in the picture parameter set exceeds 15, `num_ref_idx_active_override_flag` shall be equal to 1.

num_ref_idx_l0_active_minus1 specifies the maximum reference index for reference picture list 0 that shall be used to decode the slice.

The range of `num_ref_idx_l0_active_minus1` is specified as follows.

- If `field_pic_flag` is equal to 0, `num_ref_idx_l0_active_minus1` shall be in the range of 0 to 15, inclusive. When `MbaffFrameFlag` is equal to 1, `num_ref_idx_l0_active_minus1` is the maximum index value for the decoding of frame macroblocks and $2 * \text{num_ref_idx_l0_active_minus1} + 1$ is the maximum index value for the decoding of field macroblocks.
- Otherwise (`field_pic_flag` is equal to 1), `num_ref_idx_l0_active_minus1` shall be in the range of 0 to 31, inclusive.

num_ref_idx_l1_active_minus1 has the same semantics as `num_ref_idx_l0_active_minus1` with l0 and list 0 replaced by l1 and list 1, respectively.

cabac_init_idc specifies the index for determining the initialisation table used in the initialisation process for context variables. The value of `cabac_init_idc` shall be in the range of 0 to 2, inclusive.

slice_qp_delta specifies the initial value of QP_Y to be used for all the macroblocks in the slice until modified by the value of `mb_qp_delta` in the macroblock layer. The initial QP_Y quantisation parameter for the slice is computed as:

$$\text{SliceQP}_Y = 26 + \text{pic_init_qp_minus26} + \text{slice_qp_delta} \quad (7-27)$$

The value of `slice_qp_delta` shall be limited such that SliceQP_Y is in the range of $-\text{QpBdOffset}_Y$ to +51, inclusive.

sp_for_switch_flag specifies the decoding process to be used to decode P macroblocks in an SP slice as follows.

- If `sp_for_switch_flag` is equal to 0, the P macroblocks in the SP slice shall be decoded using the SP decoding process for non-switching pictures as specified in subclause 8.6.1.
- Otherwise (`sp_for_switch_flag` is equal to 1), the P macroblocks in the SP slice shall be decoded using the SP and SI decoding process for switching pictures as specified in subclause 8.6.2.

slice_qs_delta specifies the value of QS_Y for all the macroblocks in SP and SI slices. The QS_Y quantisation parameter for the slice is computed as:

$$QS_Y = 26 + \text{pic_init_qs_minus26} + \text{slice_qs_delta} \quad (7-28)$$

The value of `slice_qs_delta` shall be limited such that QS_Y is in the range of 0 to 51, inclusive. This value of QS_Y is used for the decoding of all macroblocks in SI slices with `mb_type` equal to SI and all macroblocks in SP slices with prediction mode equal to inter.

disable_deblocking_filter_idc specifies whether the operation of the deblocking filter shall be disabled across some block edges of the slice and specifies for which edges the filtering is disabled. When `disable_deblocking_filter_idc` is not present in the slice header, the value of `disable_deblocking_filter_idc` shall be inferred to be equal to 0.

The value of `disable_deblocking_filter_idc` shall be in the range of 0 to 2, inclusive.

slice_alpha_c0_offset_div2 specifies the offset used in accessing the α and t_{c0} deblocking filter tables for filtering operations controlled by the macroblocks within the slice. From this value, the offset that shall be applied when addressing these tables shall be computed as:

$$\text{FilterOffsetA} = \text{slice_alpha_c0_offset_div2} \ll 1 \quad (7-29)$$

The value of `slice_alpha_c0_offset_div2` shall be in the range of -6 to +6, inclusive. When `slice_alpha_c0_offset_div2` is not present in the slice header, the value of `slice_alpha_c0_offset_div2` shall be inferred to be equal to 0.

slice_beta_offset_div2 specifies the offset used in accessing the β deblocking filter table for filtering operations controlled by the macroblocks within the slice. From this value, the offset that is applied when addressing the β table of the deblocking filter shall be computed as:

$$\text{FilterOffsetB} = \text{slice_beta_offset_div2} \ll 1 \quad (7-30)$$

The value of `slice_beta_offset_div2` shall be in the range of -6 to +6, inclusive. When `slice_beta_offset_div2` is not present in the slice header the value of `slice_beta_offset_div2` shall be inferred to be equal to 0.

slice_group_change_cycle is used to derive the number of slice group map units in slice group 0 when `slice_group_map_type` is equal to 3, 4, or 5, as specified by

$$\text{MapUnitsInSliceGroup0} = \text{Min}(\text{slice_group_change_cycle} * \text{SliceGroupChangeRate}, \text{PicSizeInMapUnits}) \quad (7-31)$$

The value of `slice_group_change_cycle` is represented in the bitstream by the following number of bits

$$\text{Ceil}(\text{Log2}(\text{PicSizeInMapUnits} \div \text{SliceGroupChangeRate} + 1)) \quad (7-32)$$

The value of `slice_group_change_cycle` shall be in the range of 0 to $\text{Ceil}(\text{PicSizeInMapUnits} \div \text{SliceGroupChangeRate})$, inclusive.

7.4.3.1 Reference picture list reordering semantics

The syntax elements `reordering_of_pic_nums_idc`, `abs_diff_pic_num_minus1`, and `long_term_pic_num` specify the change from the initial reference picture lists to the reference picture lists to be used for decoding the slice.

ref_pic_list_reordering_flag_l0 equal to 1 specifies that the syntax element `reordering_of_pic_nums_idc` is present for specifying reference picture list 0. `ref_pic_list_reordering_flag_l0` equal to 0 specifies that this syntax element is not present.

When `ref_pic_list_reordering_flag_l0` is equal to 1, the number of times that `reordering_of_pic_nums_idc` is not equal to 3 following `ref_pic_list_reordering_flag_l0` shall not exceed `num_ref_idx_l0_active_minus1 + 1`.

When `RefPicList0[num_ref_idx_l0_active_minus1]` in the initial reference picture list produced as specified in subclause 8.2.4.2 is equal to "no reference picture", `ref_pic_list_reordering_flag_l0` shall be equal to 1 and `reordering_of_pic_nums_idc` shall not be equal to 3 until `RefPicList0[num_ref_idx_l0_active_minus1]` in the reordered list produced as specified in subclause 8.2.4.3 is not equal to "no reference picture".

ref_pic_list_reordering_flag_l1 equal to 1 specifies that the syntax element **reordering_of_pic_nums_idc** is present for specifying reference picture list 1. **ref_pic_list_reordering_flag_l1** equal to 0 specifies that this syntax element is not present.

When **ref_pic_list_reordering_flag_l1** is equal to 1, the number of times that **reordering_of_pic_nums_idc** is not equal to 3 following **ref_pic_list_reordering_flag_l1** shall not exceed **num_ref_idx_l1_active_minus1** + 1.

When decoding a B slice and **RefPicList1[num_ref_idx_l1_active_minus1]** in the initial reference picture list produced as specified in subclause 8.2.4.2 is equal to "no reference picture", **ref_pic_list_reordering_flag_l1** shall be equal to 1 and **reordering_of_pic_nums_idc** shall not be equal to 3 until **RefPicList1[num_ref_idx_l1_active_minus1]** in the reordered list produced as specified in subclause 8.2.4.3 is not equal to "no reference picture".

reordering_of_pic_nums_idc together with **abs_diff_pic_num_minus1** or **long_term_pic_num** specifies which of the reference pictures are re-mapped. The values of **reordering_of_pic_nums_idc** are specified in Table 7-7. The value of the first **reordering_of_pic_nums_idc** that follows immediately after **ref_pic_list_reordering_flag_l0** or **ref_pic_list_reordering_flag_l1** shall not be equal to 3.

Table 7-7 – reordering_of_pic_nums_idc operations for reordering of reference picture lists

reordering_of_pic_nums_idc	Reordering specified
0	abs_diff_pic_num_minus1 is present and corresponds to a difference to subtract from a picture number prediction value
1	abs_diff_pic_num_minus1 is present and corresponds to a difference to add to a picture number prediction value
2	long_term_pic_num is present and specifies the long-term picture number for a reference picture
3	End loop for reordering of the initial reference picture list

abs_diff_pic_num_minus1 plus 1 specifies the absolute difference between the picture number of the picture being moved to the current index in the list and the picture number prediction value. **abs_diff_pic_num_minus1** shall be in the range of 0 to **MaxPicNum** – 1. The allowed values of **abs_diff_pic_num_minus1** are further restricted as specified in subclause 8.2.4.3.1.

long_term_pic_num specifies the long-term picture number of the picture being moved to the current index in the list. When decoding a coded frame, **long_term_pic_num** shall be equal to a **LongTermPicNum** assigned to one of the reference frames or complementary reference field pairs marked as "used for long-term reference". When decoding a coded field, **long_term_pic_num** shall be equal to a **LongTermPicNum** assigned to one of the reference fields marked as "used for long-term reference".

7.4.3.2 Prediction weight table semantics

luma_log2_weight_denom is the base 2 logarithm of the denominator for all luma weighting factors. The value of **luma_log2_weight_denom** shall be in the range of 0 to 7, inclusive.

chroma_log2_weight_denom is the base 2 logarithm of the denominator for all chroma weighting factors. The value of **chroma_log2_weight_denom** shall be in the range of 0 to 7, inclusive.

luma_weight_l0_flag equal to 1 specifies that weighting factors for the luma component of list 0 prediction are present. **luma_weight_l0_flag** equal to 0 specifies that these weighting factors are not present.

luma_weight_l0[i] is the weighting factor applied to the luma prediction value for list 0 prediction using **RefPicList0[i]**. When **luma_weight_l0_flag** is equal to 1, the value of **luma_weight_l0[i]** shall be in the range of –128 to 127, inclusive. When **luma_weight_l0_flag** is equal to 0, **luma_weight_l0[i]** shall be inferred to be equal to $2^{\text{luma_log2_weight_denom}}$ for **RefPicList0[i]**.

luma_offset_l0[i] is the additive offset applied to the luma prediction value for list 0 prediction using **RefPicList0[i]**. The value of **luma_offset_l0[i]** shall be in the range of –128 to 127, inclusive. When **luma_weight_l0_flag** is equal to 0, **luma_offset_l0[i]** shall be inferred as equal to 0 for **RefPicList0[i]**.

chroma_weight_l0_flag equal to 1 specifies that weighting factors for the chroma prediction values of list 0 prediction are present. **chroma_weight_l0_flag** equal to 0 specifies that these weighting factors are not present.

chroma_weight_l0[i][j] is the weighting factor applied to the chroma prediction values for list 0 prediction using RefPicList0[i] with j equal to 0 for Cb and j equal to 1 for Cr. When chroma_weight_l0_flag is equal to 1, the value of chroma_weight_l0[i][j] shall be in the range of -128 to 127, inclusive. When chroma_weight_l0_flag is equal to 0, chroma_weight_l0[i][j] shall be inferred to be equal to $2^{\text{chroma_log2_weight_denom}}$ for RefPicList0[i].

chroma_offset_l0[i][j] is the additive offset applied to the chroma prediction values for list 0 prediction using RefPicList0[i] with j equal to 0 for Cb and j equal to 1 for Cr. The value of chroma_offset_l0[i][j] shall be in the range of -128 to 127, inclusive. When chroma_weight_l0_flag is equal to 0, chroma_offset_l0[i][j] shall be inferred to be equal to 0 for RefPicList0[i].

luma_weight_l1_flag, luma_weight_l1, luma_offset_l1, chroma_weight_l1_flag, chroma_weight_l1, chroma_offset_l1 have the same semantics as luma_weight_l0_flag, luma_weight_l0, luma_offset_l0, chroma_weight_l0_flag, chroma_weight_l0, chroma_offset_l0, respectively, with l0, list 0, and List0 replaced by l1, list 1, and List1, respectively.

7.4.3.3 Decoded reference picture marking semantics

The syntax elements no_output_of_prior_pics_flag, long_term_reference_flag, adaptive_ref_pic_marking_mode_flag, memory_management_control_operation, difference_of_pic_nums_minus1, long_term_frame_idx, long_term_pic_num, and max_long_term_frame_idx_plus1 specify marking of the reference pictures.

The marking of a reference picture can be "unused for reference", "used for short-term reference", or "used for long-term reference", but only one among these three. When a reference picture is referred to as being marked as "used for reference", this collectively refers to the picture being marked as "used for short-term reference" or "used for long-term reference" (but not both). A reference picture that is marked as "used for short-term reference" is referred to as a short-term reference picture. A reference picture that is marked as "used for long-term reference" is referred to as a long-term reference picture.

The syntax element adaptive_ref_pic_marking_mode_flag and the content of the decoded reference picture marking syntax structure shall be identical for all coded slices of a coded picture.

The syntax category of the decoded reference picture marking syntax structure shall be inferred as follows.

- If the decoded reference picture marking syntax structure is in a slice header, the syntax category of the decoded reference picture marking syntax structure shall be inferred to be equal to 2.
- Otherwise (the decoded reference picture marking syntax structure is in a decoded reference picture marking repetition SEI message as specified in Annex D), the syntax category of the decoded reference picture marking syntax structure shall be inferred to be equal to 5.

no_output_of_prior_pics_flag specifies how the previously-decoded pictures in the decoded picture buffer are treated after decoding of an IDR picture. See Annex C. When the IDR picture is the first IDR picture in the bitstream, the value of no_output_of_prior_pics_flag has no effect on the decoding process. When the IDR picture is not the first IDR picture in the bitstream and the value of PicWidthInMbs, FrameHeightInMbs, or max_dec_frame_buffering derived from the active sequence parameter set is different from the value of PicWidthInMbs, FrameHeightInMbs, or max_dec_frame_buffering derived from the sequence parameter set active for the preceding sequence, no_output_of_prior_pics_flag equal to 1 may be inferred by the decoder, regardless of the actual value of no_output_of_prior_pics_flag.

long_term_reference_flag equal to 0 specifies that the MaxLongTermFrameIdx variable is set equal to "no long-term frame indices" and that the IDR picture is marked as "used for short-term reference". long_term_reference_flag equal to 1 specifies that the MaxLongTermFrameIdx variable is set equal to 0 and that the current IDR picture is marked "used for long-term reference" and is assigned LongTermFrameIdx equal to 0. When num_ref_frames is equal to 0, long_term_reference_flag shall be equal to 0.

adaptive_ref_pic_marking_mode_flag selects the reference picture marking mode of the currently decoded picture as specified in Table 7-8. adaptive_ref_pic_marking_mode_flag shall be equal to 1 when the number of frames, complementary field pairs, and non-paired fields that are currently marked as "used for long-term reference" is equal to Max(num_ref_frames, 1).

Table 7-8 – Interpretation of adaptive_ref_pic_marking_mode_flag

adaptive_ref_pic_marking_mode_flag	Reference picture marking mode specified
0	Sliding window reference picture marking mode: A marking mode providing a first-in first-out mechanism for short-term reference pictures.
1	Adaptive reference picture marking mode: A reference picture marking mode providing syntax elements to specify marking of reference pictures as “unused for reference” and to assign long-term frame indices.

memory_management_control_operation specifies a control operation to be applied to affect the reference picture marking. The `memory_management_control_operation` syntax element is followed by data necessary for the operation specified by the value of `memory_management_control_operation`. The values and control operations associated with `memory_management_control_operation` are specified in Table 7-9. The `memory_management_control_operation` syntax elements are processed by the decoding process in the order in which they appear in the slice header, and the semantics constraints expressed for each `memory_management_control_operation` apply at the specific position in that order at which that individual `memory_management_control_operation` is processed.

For interpretation of `memory_management_control_operation`, the term reference picture is interpreted as follows.

- If the current picture is a frame, the term reference picture refers either to a reference frame or a complementary reference field pair.
- Otherwise (the current picture is a field), the term reference picture refers either to a reference field or a field of a reference frame.

`memory_management_control_operation` shall not be equal to 1 in a slice header unless the specified reference picture is marked as "used for short-term reference" when the `memory_management_control_operation` is processed by the decoding process.

`memory_management_control_operation` shall not be equal to 2 in a slice header unless the specified long-term picture number refers to a reference picture that is marked as "used for long-term reference" when the `memory_management_control_operation` is processed by the decoding process.

`memory_management_control_operation` shall not be equal to 3 in a slice header unless the specified reference picture is marked as "used for short-term reference" when the `memory_management_control_operation` is processed by the decoding process.

`memory_management_control_operation` shall not be equal to 3 or 6 if the value of the variable `MaxLongTermFrameIdx` is equal to "no long-term frame indices" when the `memory_management_control_operation` is processed by the decoding process.

Not more than one `memory_management_control_operation` equal to 4 shall be present in a slice header.

Not more than one `memory_management_control_operation` equal to 5 shall be present in a slice header.

Not more than one `memory_management_control_operation` equal to 6 shall be present in a slice header.

`memory_management_control_operation` shall not be equal to 5 in a slice header unless no `memory_management_control_operation` in the range of 1 to 3 is present in the same decoded reference picture marking syntax structure.

A `memory_management_control_operation` equal to 5 shall not follow a `memory_management_control_operation` equal to 6 in the same slice header.

When a `memory_management_control_operation` equal to 6 is present, any `memory_management_control_operation` equal to 2, 3, or 4 that follows the `memory_management_control_operation` equal to 6 within the same slice header shall not specify the current picture to be marked as "unused for reference".

NOTE 1 – These constraints prohibit any combination of multiple `memory_management_control_operation` syntax elements that would specify the current picture to be marked as "unused for reference". However, some other combinations of `memory_management_control_operation` syntax elements are permitted that may affect the marking status of other reference pictures more than once in the same slice header. In particular, it is permitted for a `memory_management_control_operation` equal to 3 that specifies a long-term frame index to be assigned to a particular short-term reference picture to be followed in the same slice header by a `memory_management_control_operation` equal to 2, 3, 4 or 6 that specifies the same reference picture to subsequently be marked as "unused for reference".

Table 7-9 – Memory management control operation (memory_management_control_operation) values

memory_management_control_operation	Memory Management Control Operation
0	End memory_management_control_operation syntax element loop
1	Mark a short-term reference picture as "unused for reference"
2	Mark a long-term reference picture as "unused for reference"
3	Mark a short-term reference picture as "used for long-term reference" and assign a long-term frame index to it
4	Specify the maximum long-term frame index and mark all long-term reference pictures having long-term frame indices greater than the maximum value as "unused for reference"
5	Mark all reference pictures as "unused for reference" and set the MaxLongTermFrameIdx variable to "no long-term frame indices"
6	Mark the current picture as "used for long-term reference" and assign a long-term frame index to it

When decoding a field and a memory_management_control_operation command equal to 3 is present that assigns a long-term frame index to a field that is part of a short-term reference frame or part of a short-term complementary reference field pair, another memory_management_control_operation command to assign the same long-term frame index to the other field of the same frame or complementary reference field pair shall be present in the same decoded reference picture marking syntax structure.

NOTE 2 – The above requirement must be fulfilled even when the field referred to by the memory_management_control_operation equal to 3 is subsequently marked as "unused for reference" (for example when a memory_management_control_operation equal to 2 is present in the same slice header that causes the field to be marked as "unused for reference").

When the first field (in decoding order) of a complementary reference field pair includes a long_term_reference_flag equal to 1 or a memory_management_control_operation command equal to 6, the decoded reference picture marking syntax structure for the other field of the complementary reference field pair shall contain a memory_management_control_operation command equal to 6 that assigns the same long-term frame index to the other field.

NOTE 3 – The above requirement must be fulfilled even when the first field of the complementary reference field pair is subsequently marked as "unused for reference" (for example, when a memory_management_control_operation equal to 2 is present in the slice header of the second field that causes the first field to be marked as "unused for reference").

difference_of_pic_nums_minus1 is used (with memory_management_control_operation equal to 3 or 1) to assign a long-term frame index to a short-term reference picture or to mark a short-term reference picture as "unused for reference". When the associated memory_management_control_operation is processed by the decoding process, the resulting picture number derived from difference_of_pic_nums_minus1 shall be a picture number assigned to one of the reference pictures marked as "used for reference" and not previously assigned to a long-term frame index.

The resulting picture number is constrained as follows.

- If field_pic_flag is equal to 0, the resulting picture number shall be one of the set of picture numbers assigned to reference frames or complementary reference field pairs.

NOTE 4 – When field_pic_flag is equal to 0, the resulting picture number must be a picture number assigned to a complementary reference field pair in which both fields are marked as "used for reference" or a frame in which both fields are marked as "used for reference". In particular, when field_pic_flag is equal to 0, the marking of a non-paired field or a frame in which a single field is marked as "used for reference" cannot be affected by a memory_management_control_operation equal to 1.

- Otherwise (field_pic_flag is equal to 1), the resulting picture number shall be one of the set of picture numbers assigned to reference fields.

long_term_pic_num is used (with `memory_management_control_operation` equal to 2) to mark a long-term reference picture as "unused for reference". When the associated `memory_management_control_operation` is processed by the decoding process, `long_term_pic_num` shall be equal to a long-term picture number assigned to one of the reference pictures that is currently marked as "used for long-term reference".

The resulting long-term picture number is constrained as follows.

- If `field_pic_flag` is equal to 0, the resulting long-term picture number shall be one of the set of long-term picture numbers assigned to reference frames or complementary reference field pairs.

NOTE 5 – When `field_pic_flag` is equal to 0, the resulting long-term picture number must be a long-term picture number assigned to a complementary reference field pair in which both fields are marked as "used for reference" or a frame in which both fields are marked as "used for reference". In particular, when `field_pic_flag` is equal to 0, the marking of a non-paired field or a frame in which a single field is marked as "used for reference" cannot be affected by a `memory_management_control_operation` equal to 2.

- Otherwise (`field_pic_flag` is equal to 1), the resulting long-term picture number shall be one of the set of long-term picture numbers assigned to reference fields.

long_term_frame_idx is used (with `memory_management_control_operation` equal to 3 or 6) to assign a long-term frame index to a picture. When the associated `memory_management_control_operation` is processed by the decoding process, the value of `long_term_frame_idx` shall be in the range of 0 to `MaxLongTermFrameIdx`, inclusive.

max_long_term_frame_idx_plus1 minus 1 specifies the maximum value of long-term frame index allowed for long-term reference pictures (until receipt of another value of `max_long_term_frame_idx_plus1`). The value of `max_long_term_frame_idx_plus1` shall be in the range of 0 to `num_ref_frames`, inclusive.

7.4.4 Slice data semantics

cabac_alignment_one_bit is a bit equal to 1.

mb_skip_run specifies the number of consecutive skipped macroblocks for which, when decoding a P or SP slice, `mb_type` shall be inferred to be `P_Skip` and the macroblock type is collectively referred to as a P macroblock type, or for which, when decoding a B slice, `mb_type` shall be inferred to be `B_Skip` and the macroblock type is collectively referred to as a B macroblock type. The value of `mb_skip_run` shall be in the range of 0 to `PicSizeInMbs – CurrMbAddr`, inclusive.

mb_skip_flag equal to 1 specifies that for the current macroblock, when decoding a P or SP slice, `mb_type` shall be inferred to be `P_Skip` and the macroblock type is collectively referred to as P macroblock type, or for which, when decoding a B slice, `mb_type` shall be inferred to be `B_Skip` and the macroblock type is collectively referred to as B macroblock type. `mb_skip_flag` equal to 0 specifies that the current macroblock is not skipped.

mb_field_decoding_flag equal to 0 specifies that the current macroblock pair is a frame macroblock pair. `mb_field_decoding_flag` equal to 1 specifies that the macroblock pair is a field macroblock pair. Both macroblocks of a frame macroblock pair are referred to in the text as frame macroblocks, whereas both macroblocks of a field macroblock pair are referred to in the text as field macroblocks.

When `mb_field_decoding_flag` is not present for either macroblock of a macroblock pair, the value of `mb_field_decoding_flag` is derived as follows.

- If there is a neighbouring macroblock pair immediately to the left of the current macroblock pair in the same slice, the value of `mb_field_decoding_flag` shall be inferred to be equal to the value of `mb_field_decoding_flag` for the neighbouring macroblock pair immediately to the left of the current macroblock pair,
- Otherwise, if there is no neighbouring macroblock pair immediately to the left of the current macroblock pair in the same slice and there is a neighbouring macroblock pair immediately above the current macroblock pair in the same slice, the value of `mb_field_decoding_flag` shall be inferred to be equal to the value of `mb_field_decoding_flag` for the neighbouring macroblock pair immediately above the current macroblock pair,
- Otherwise (there is no neighbouring macroblock pair either immediately to the left or immediately above the current macroblock pair in the same slice), the value of `mb_field_decoding_flag` shall be inferred to be equal to 0.

end_of_slice_flag equal to 0 specifies that another macroblock is following in the slice. `end_of_slice_flag` equal to 1 specifies the end of the slice and that no further macroblock follows.

The function `NextMbAddress()` used in the slice data syntax table is specified in subclause 8.2.2.

7.4.5 Macroblock layer semantics

mb_type specifies the macroblock type. The semantics of `mb_type` depend on the slice type.

Tables and semantics are specified for the various macroblock types for I, SI, P, SP, and B slices. Each table presents the value of mb_type, the name of mb_type, the number of macroblock partitions used (given by the NumMbPart(mb_type) function), the prediction mode of the macroblock (when it is not partitioned) or the first partition (given by the MbPartPredMode(mb_type, 0) function) and the prediction mode of the second partition (given by the MbPartPredMode(mb_type, 1) function). When a value is not applicable it is designated by “na”. In the text, the value of mb_type may be referred to as the macroblock type and a value X of MbPartPredMode() may be referred to in the text by “X macroblock (partition) prediction mode” or as “X prediction macroblocks”.

Table 7-10 shows the allowed collective macroblock types for each slice_type.

NOTE 1 – There are some macroblock types with Pred_L0 prediction mode that are classified as B macroblock types.

Table 7-10 – Allowed collective macroblock types for slice_type

slice_type	allowed collective macroblock types
I (slice)	I (see Table 7-11) (macroblock types)
P (slice)	P (see Table 7-13) and I (see Table 7-11) (macroblock types)
B (slice)	B (see Table 7-14) and I (see Table 7-11) (macroblock types)
SI (slice)	SI (see Table 7-12) and I (see Table 7-11) (macroblock types)
SP (slice)	P (see Table 7-13) and I (see Table 7-11) (macroblock types)

transform_size_8x8_flag equal to 1 specifies that for the current macroblock the transform coefficient decoding process and picture construction process prior to deblocking filter process for residual 8x8 blocks shall be invoked for luma samples. transform_size_8x8_flag equal to 0 specifies that for the current macroblock the transform coefficient decoding process and picture construction process prior to deblocking filter process for residual 4x4 blocks shall be invoked for luma samples. When transform_size_8x8_flag is not present in the bitstream, it shall be inferred to be equal to 0.

NOTE 2 – When the current macroblock prediction mode MbPartPredMode(mb_type, 0) is equal to Intra_16x16, transform_size_8x8_flag is not present in the bitstream and then inferred to be equal to 0.

When sub_mb_type[mbPartIdx] (see subclause 7.4.5.2) is present in the bitstream for all 8x8 blocks indexed by mbPartIdx = 0..3, the variable noSubMbPartSizeLessThan8x8Flag indicates whether for each of the four 8x8 blocks the corresponding SubMbPartWidth(sub_mb_type[mbPartIdx]) and SubMbPartHeight(sub_mb_type[mbPartIdx]) are both equal to 8.

NOTE 3 – When noSubMbPartSizeLessThan8x8Flag is equal to 0 and the current macroblock type is not equal to I_NxN, transform_size_8x8_flag is not present in the bitstream and then inferred to be equal to 0.

Macroblock types that may be collectively referred to as I macroblock types are specified in Table 7-11.

The macroblock types for I slices are all I macroblock types.

Table 7-11 – Macroblock types for I slices

mb_type	Name of mb_type	transform_size_8x8_flag	MbPartPredMode (mb_type, 0)	Intra16x16PredMode	CodedBlockPatternChroma	CodedBlockPatternLuma
0	I_NxN	0	Intra_4x4	na	Equation 7-33	Equation 7-33
0	I_NxN	1	Intra_8x8	na	Equation 7-33	Equation 7-33
1	I_16x16_0_0_0	na	Intra_16x16	0	0	0
2	I_16x16_1_0_0	na	Intra_16x16	1	0	0
3	I_16x16_2_0_0	na	Intra_16x16	2	0	0
4	I_16x16_3_0_0	na	Intra_16x16	3	0	0
5	I_16x16_0_1_0	na	Intra_16x16	0	1	0
6	I_16x16_1_1_0	na	Intra_16x16	1	1	0
7	I_16x16_2_1_0	na	Intra_16x16	2	1	0
8	I_16x16_3_1_0	na	Intra_16x16	3	1	0
9	I_16x16_0_2_0	na	Intra_16x16	0	2	0
10	I_16x16_1_2_0	na	Intra_16x16	1	2	0
11	I_16x16_2_2_0	na	Intra_16x16	2	2	0
12	I_16x16_3_2_0	na	Intra_16x16	3	2	0
13	I_16x16_0_0_1	na	Intra_16x16	0	0	15
14	I_16x16_1_0_1	na	Intra_16x16	1	0	15
15	I_16x16_2_0_1	na	Intra_16x16	2	0	15
16	I_16x16_3_0_1	na	Intra_16x16	3	0	15
17	I_16x16_0_1_1	na	Intra_16x16	0	1	15
18	I_16x16_1_1_1	na	Intra_16x16	1	1	15
19	I_16x16_2_1_1	na	Intra_16x16	2	1	15
20	I_16x16_3_1_1	na	Intra_16x16	3	1	15
21	I_16x16_0_2_1	na	Intra_16x16	0	2	15
22	I_16x16_1_2_1	na	Intra_16x16	1	2	15
23	I_16x16_2_2_1	na	Intra_16x16	2	2	15
24	I_16x16_3_2_1	na	Intra_16x16	3	2	15
25	I_PCM	na	na	na	na	na

The following semantics are assigned to the macroblock types in Table 7-11.

I_NxN: A mnemonic name for mb_type equal to 0 with MbPartPredMode(mb_type, 0) equal to Intra_4x4 or Intra_8x8.

I_16x16_0_0_0, I_16x16_1_0_0, I_16x16_2_0_0, I_16x16_3_0_0, I_16x16_0_1_0, I_16x16_1_1_0, I_16x16_2_1_0, I_16x16_3_1_0, I_16x16_0_2_0, I_16x16_1_2_0, I_16x16_2_2_0, I_16x16_3_2_0, I_16x16_0_0_1, I_16x16_1_0_1, I_16x16_2_0_1, I_16x16_3_0_1, I_16x16_0_1_1, I_16x16_1_1_1, I_16x16_2_1_1, I_16x16_3_1_1, I_16x16_0_2_1, I_16x16_1_2_1, I_16x16_2_2_1, I_16x16_3_2_1: the macroblock is coded as an Intra_16x16 prediction mode macroblock.

To each Intra_16x16 prediction macroblock, an Intra16x16PredMode is assigned, which specifies the Intra_16x16 prediction mode. CodedBlockPatternChroma contains the coded block pattern value for chroma as specified in Table 7-15. When chroma_format_idc is equal to 0, CodedBlockPatternChroma shall be equal to 0. CodedBlockPatternLuma specifies whether, for the luma component, non-zero AC transform coefficient levels are present. CodedBlockPatternLuma equal to 0 specifies that all AC transform coefficient levels in the luma component of the macroblock are equal to 0. CodedBlockPatternLuma equal to 15 specifies that at least one of the AC transform coefficient levels in the luma component of the macroblock is non-zero, requiring scanning of AC transform coefficient levels for all 16 of the 4x4 blocks in the 16x16 block.

Intra_4x4 specifies the macroblock prediction mode and specifies that the Intra_4x4 prediction process is invoked as specified in subclause 8.3.1. Intra_4x4 is an Intra macroblock prediction mode.

Intra_8x8 specifies the macroblock prediction mode and specifies that the Intra_8x8 prediction process is invoked as specified in subclause 8.3.2. Intra_8x8 is an Intra macroblock prediction mode.

Intra_16x16 specifies the macroblock prediction mode and specifies that the Intra_16x16 prediction process is invoked as specified in subclause 8.3.3. Intra_16x16 is an Intra macroblock prediction mode.

For a macroblock coded with mb_type equal to I_PCM, the Intra macroblock prediction mode shall be inferred.

A macroblock type that may be referred to as SI macroblock type is specified in Table 7-12.

The macroblock types for SI slices are specified in Tables 7-12 and 7-11. The mb_type value 0 is specified in Table 7-12 and the mb_type values 1 to 26 are specified in Table 7-11, indexed by subtracting 1 from the value of mb_type.

Table 7-12 – Macroblock type with value 0 for SI slices

mb_type	Name of mb_type	MbPartPredMode (mb_type, 0)	Intra16x16PredMode	CodedBlockPatternChroma	CodedBlockPatternLuma
0	SI	Intra_4x4	na	Equation 7-33	Equation 7-33

The following semantics are assigned to the macroblock type in Table 7-12. The SI macroblock is coded as Intra_4x4 prediction macroblock.

Macroblock types that may be collectively referred to as P macroblock types are specified in Table 7-13.

The macroblock types for P and SP slices are specified in Tables 7-13 and 7-11. mb_type values 0 to 4 are specified in Table 7-13 and mb_type values 5 to 30 are specified in Table 7-11, indexed by subtracting 5 from the value of mb_type.

Table 7-13 – Macroblock type values 0 to 4 for P and SP slices

mb_type	Name of mb_type	NumMbPart (mb_type)	MbPartPredMode (mb_type, 0)	MbPartPredMode (mb_type, 1)	MbPartWidth (mb_type)	MbPartHeight (mb_type)
0	P_L0_16x16	1	Pred_L0	na	16	16
1	P_L0_L0_16x8	2	Pred_L0	Pred_L0	16	8
2	P_L0_L0_8x16	2	Pred_L0	Pred_L0	8	16
3	P_8x8	4	na	na	8	8
4	P_8x8ref0	4	na	na	8	8
inferred	P_Skip	1	Pred_L0	na	16	16

The following semantics are assigned to the macroblock types in Table 7-13.

- P_L0_16x16: the samples of the macroblock are predicted with one luma macroblock partition of size 16x16 luma samples and associated chroma samples.
- P_L0_L0_MxN, with MxN being replaced by 16x8 or 8x16: the samples of the macroblock are predicted using two luma partitions of size MxN equal to 16x8, or two luma partitions of size MxN equal to 8x16, and associated chroma samples, respectively.
- P_8x8: for each sub-macroblock an additional syntax element (sub_mb_type) is present in the bitstream that specifies the type of the corresponding sub-macroblock (see subclause 7.4.5.2).
- P_8x8ref0: has the same semantics as P_8x8 but no syntax element for the reference index (ref_idx_l0) is present in the bitstream and ref_idx_l0[mbPartIdx] shall be inferred to be equal to 0 for all sub-macroblocks of the macroblock (with indices mbPartIdx equal to 0..3).
- P_Skip: no further data is present for the macroblock in the bitstream.

The following semantics are assigned to the macroblock prediction modes (MbPartPredMode()) in Table 7-13.

- Pred_L0: specifies that the inter prediction process is invoked using list 0 prediction. Pred_L0 is an Inter macroblock prediction mode.

Macroblock types that may be collectively referred to as B macroblock types are specified in Table 7-14.

The macroblock types for B slices are specified in Tables 7-14 and 7-11. The mb_type values 0 to 22 are specified in Table 7-14 and the mb_type values 23 to 48 are specified in Table 7-11, indexed by subtracting 23 from the value of mb_type.

Table 7-14 – Macroblock type values 0 to 22 for B slices

mb_type	Name of mb_type	NumMbPart (mb_type)	MbPartPredMode (mb_type, 0)	MbPartPredMode (mb_type, 1)	MbPartWidth (mb_type)	MbPartHeight (mb_type)
0	B_Direct_16x16	na	Direct	na	8	8
1	B_L0_16x16	1	Pred_L0	na	16	16
2	B_L1_16x16	1	Pred_L1	na	16	16
3	B_Bi_16x16	1	BiPred	na	16	16
4	B_L0_L0_16x8	2	Pred_L0	Pred_L0	16	8
5	B_L0_L0_8x16	2	Pred_L0	Pred_L0	8	16
6	B_L1_L1_16x8	2	Pred_L1	Pred_L1	16	8
7	B_L1_L1_8x16	2	Pred_L1	Pred_L1	8	16
8	B_L0_L1_16x8	2	Pred_L0	Pred_L1	16	8
9	B_L0_L1_8x16	2	Pred_L0	Pred_L1	8	16
10	B_L1_L0_16x8	2	Pred_L1	Pred_L0	16	8
11	B_L1_L0_8x16	2	Pred_L1	Pred_L0	8	16
12	B_L0_Bi_16x8	2	Pred_L0	BiPred	16	8
13	B_L0_Bi_8x16	2	Pred_L0	BiPred	8	16
14	B_L1_Bi_16x8	2	Pred_L1	BiPred	16	8
15	B_L1_Bi_8x16	2	Pred_L1	BiPred	8	16
16	B_Bi_L0_16x8	2	BiPred	Pred_L0	16	8
17	B_Bi_L0_8x16	2	BiPred	Pred_L0	8	16
18	B_Bi_L1_16x8	2	BiPred	Pred_L1	16	8
19	B_Bi_L1_8x16	2	BiPred	Pred_L1	8	16
20	B_Bi_Bi_16x8	2	BiPred	BiPred	16	8
21	B_Bi_Bi_8x16	2	BiPred	BiPred	8	16
22	B_8x8	4	na	na	8	8
inferred	B_Skip	na	Direct	na	8	8

The following semantics are assigned to the macroblock types in Table 7-14:

- B_Direct_16x16: no motion vector differences or reference indices are present for the macroblock in the bitstream. The functions MbPartWidth(B_Direct_16x16), and MbPartHeight(B_Direct_16x16) are used in the derivation process for motion vectors and reference frame indices in subclause 8.4.1 for direct mode prediction.
- B_X_16x16 with X being replaced by L0, L1, or Bi: the samples of the macroblock are predicted with one luma macroblock partition of size 16x16 luma samples and associated chroma samples. For a macroblock with type B_X_16x16 with X being replaced by either L0 or L1, one motion vector difference and one reference index is

present in the bitstream for the macroblock. For a macroblock with type B_X_16x16 with X being replaced by Bi, two motion vector differences and two reference indices are present in the bitstream for the macroblock.

- B_X0_X1_MxN, with X0, X1 referring to the first and second macroblock partition and being replaced by L0, L1, or Bi, and MxN being replaced by 16x8 or 8x16: the samples of the macroblock are predicted using two luma partitions of size MxN equal to 16x8, or two luma partitions of size MxN equal to 8x16, and associated chroma samples, respectively. For a macroblock partition X0 or X1 with X0 or X1 being replaced by either L0 or L1, one motion vector difference and one reference index is present in the bitstream. For a macroblock partition X0 or X1 with X0 or X1 being replaced by Bi, two motion vector differences and two reference indices are present in the bitstream for the macroblock partition.
- B_8x8: for each sub-macroblock an additional syntax element (sub_mb_type) is present in the bitstream that specifies the type of the corresponding sub-macroblock (see subclause 7.4.5.2).
- B_Skip: no further data is present for the macroblock in the bitstream. The functions MbPartWidth(B_Skip), and MbPartHeight(B_Skip) are used in the derivation process for motion vectors and reference frame indices in subclause 8.4.1 for direct mode prediction.

The following semantics are assigned to the macroblock prediction modes (MbPartPredMode()) in Table 7-14.

- Direct: no motion vector differences or reference indices are present for the macroblock (in case of B_Skip or B_Direct_16x16) in the bitstream. Direct is an Inter macroblock prediction mode.
- Pred_L0: see semantics for Table 7-13.
- Pred_L1: specifies that the Inter prediction process is invoked using list 1 prediction. Pred_L1 is an Inter macroblock prediction mode.
- BiPred: specifies that the Inter prediction process is invoked using list 0 and list 1 prediction. BiPred is an Inter macroblock prediction mode.

pcm_alignment_zero_bit is a bit equal to 0.

pcm_sample_luma[i] is a sample value. The first pcm_sample_luma[i] values represent luma sample values in the raster scan within the macroblock. The number of bits used to represent each of these samples is BitDepth_Y. When profile_idc is not equal to 100, 110, 122, or 144, pcm_sample_luma[i] shall not be equal to 0.

pcm_sample_chroma[i] is a sample value. The first MbWidthC * MbHeightC pcm_sample_chroma[i] values represent Cb sample values in the raster scan within the macroblock and the remaining MbWidthC * MbHeightC pcm_sample_chroma[i] values represent Cr sample values in the raster scan within the macroblock. The number of bits used to represent each of these samples is BitDepth_C. When profile_idc is not equal to 100, 110, 122, or 144, pcm_sample_chroma[i] shall not be equal to 0.

coded_block_pattern specifies which of the four 8x8 luma blocks and associated chroma blocks of a macroblock may contain non-zero transform coefficient levels. For macroblocks with prediction mode not equal to Intra_16x16, coded_block_pattern is present in the bitstream and the variables CodedBlockPatternLuma and CodedBlockPatternChroma are derived as follows.

$$\begin{aligned} \text{CodedBlockPatternLuma} &= \text{coded_block_pattern} \% 16 \\ \text{CodedBlockPatternChroma} &= \text{coded_block_pattern} / 16 \end{aligned} \quad (7-33)$$

When coded_block_pattern is present, CodedBlockPatternLuma specifies, for each of the four 8x8 luma blocks of the macroblock, one of the following cases.

- All transform coefficient levels of the four 4x4 luma blocks in the 8x8 luma block are equal to zero
- One or more transform coefficient levels of one or more of the 4x4 luma blocks in the 8x8 luma block shall be non-zero valued.

The meaning of CodedBlockPatternChroma is specified in Table 7-15.

Table 7-15 – Specification of CodedBlockPatternChroma values

CodedBlockPatternChroma	Description
0	All chroma transform coefficient levels are equal to 0.
1	One or more chroma DC transform coefficient levels shall be non-zero valued. All chroma AC transform coefficient levels are equal to 0.
2	Zero or more chroma DC transform coefficient levels are non-zero valued. One or more chroma AC transform coefficient levels shall be non-zero valued.

mb_qp_delta can change the value of QP_Y in the macroblock layer. The decoded value of **mb_qp_delta** shall be in the range of $-(26 + QpBdOffset_Y / 2)$ to $+(25 + QpBdOffset_Y / 2)$, inclusive. **mb_qp_delta** shall be inferred to be equal to 0 when it is not present for any macroblock (including P_Skip and B_Skip macroblock types).

The value of QP_Y is derived as

$$QP_Y = ((QP_{Y,PREV} + mb_qp_delta + 52 + 2 * QpBdOffset_Y) \% (52 + QpBdOffset_Y)) - QpBdOffset_Y \quad (7-34)$$

where $QP_{Y,PREV}$ is the luma quantisation parameter, QP_Y , of the previous macroblock in decoding order in the current slice. For the first macroblock in the slice $QP_{Y,PREV}$ is initially set equal to $SliceQP_Y$ derived in Equation 7-27 at the start of each slice.

The value of QP'_Y is derived as

$$QP'_Y = QP_Y + QpBdOffset_Y \quad (7-35)$$

7.4.5.1 Macroblock prediction semantics

All samples of the macroblock are predicted. The prediction modes are derived using the following syntax elements.

prev_intra4x4_pred_mode_flag[luma4x4BlkIdx] and **rem_intra4x4_pred_mode**[luma4x4BlkIdx] specify the Intra_4x4 prediction of the 4x4 luma block with index luma4x4BlkIdx = 0..15.

prev_intra8x8_pred_mode_flag[luma8x8BlkIdx] and **rem_intra8x8_pred_mode**[luma8x8BlkIdx] specify the Intra_8x8 prediction of the 8x8 luma block with index luma8x8BlkIdx = 0..3.

intra_chroma_pred_mode specifies the type of spatial prediction used for chroma in macroblocks using Intra_4x4 or Intra_16x16 prediction, as shown in Table 7-16. The value of **intra_chroma_pred_mode** shall be in the range of 0 to 3, inclusive.

Table 7-16 – Relationship between intra_chroma_pred_mode and spatial prediction modes

intra_chroma_pred_mode	Intra Chroma Prediction Mode
0	DC
1	Horizontal
2	Vertical
3	Plane

ref_idx_l0[mbPartIdx] when present, specifies the index in reference picture list 0 of the reference picture to be used for prediction.

The range of **ref_idx_l0**[mbPartIdx], the index in list 0 of the reference picture, and, if applicable, the parity of the field within the reference picture used for prediction are specified as follows.

- If MbaffFrameFlag is equal to 0 or mb_field_decoding_flag is equal to 0, the value of **ref_idx_l0**[mbPartIdx] shall be in the range of 0 to num_ref_idx_l0_active_minus1, inclusive.

- Otherwise (MbaffFrameFlag is equal to 1 and mb_field_decoding_flag is equal to 1), the value of ref_idx_l0[mbPartIdx] shall be in the range of 0 to 2 * num_ref_idx_l0_active_minus1 + 1, inclusive.

When only one reference picture is used for inter prediction, the values of ref_idx_l0[mbPartIdx] shall be inferred to be equal to 0.

ref_idx_l1[mbPartIdx] has the same semantics as ref_idx_l0, with l0 and list 0 replaced by l1 and list 1, respectively.

mvd_l0[mbPartIdx][0][compIdx] specifies the difference between a vector component to be used and its prediction. The index mbPartIdx specifies to which macroblock partition mvd_l0 is assigned. The partitioning of the macroblock is specified by mb_type. The horizontal motion vector component difference is decoded first in decoding order and is assigned CompIdx = 0. The vertical motion vector component is decoded second in decoding order and is assigned CompIdx = 1. The range of the components of mvd_l0[mbPartIdx][0][compIdx] is specified by constraints on the motion vector variable values derived from it as specified in Annex A.

mvd_l1[mbPartIdx][0][compIdx] has the same semantics as mvd_l0, with l0 and L0 replaced by l1 and L1, respectively.

7.4.5.2 Sub-macroblock prediction semantics

sub_mb_type[mbPartIdx] specifies the sub-macroblock types.

Tables and semantics are specified for the various sub-macroblock types for P, and B macroblock types. Each table presents the value of sub_mb_type, the name of sub_mb_type, the number of sub-macroblock partitions used (given by the NumSubMbPart(sub_mb_type) function), and the prediction mode of the sub-macroblock (given by the SubMbPredMode(sub_mb_type) function). In the text, the value of sub_mb_type may be referred to by “sub-macroblock type”. In the text, the value of SubMbPredMode() may be referred to by “sub-macroblock prediction mode”.

The interpretation of sub_mb_type[mbPartIdx] for P macroblock types is specified in Table 7-17, where the row for “inferred” specifies values inferred when sub_mb_type[mbPartIdx] is not present.

Table 7-17 – Sub-macroblock types in P macroblocks

sub_mb_type[mbPartIdx]	Name of sub_mb_type[mbPartIdx]	NumSubMbPart (sub_mb_type[mbPartIdx])	SubMbPredMode (sub_mb_type[mbPartIdx])	SubMbPartWidth (sub_mb_type[mbPartIdx])	SubMbPartHeight (sub_mb_type[mbPartIdx])
inferred	na	na	na	na	na
0	P_L0_8x8	1	Pred_L0	8	8
1	P_L0_8x4	2	Pred_L0	8	4
2	P_L0_4x8	2	Pred_L0	4	8
3	P_L0_4x4	4	Pred_L0	4	4

The following semantics are assigned to the sub-macroblock types in Table 7-17.

- P_L0_MxN, with MxN being replaced by 8x8, 8x4, 4x8, or 4x4: the samples of the sub-macroblock are predicted using one luma partition of size MxN equal to 8x8, two luma partitions of size MxN equal to 8x4, or two luma partitions of size MxN equal to 4x8, or four luma partitions of size MxN equal to 4x4, and associated chroma samples, respectively.

The following semantics are assigned to the sub-macroblock prediction modes (SubMbPredMode()) in Table 7-17.

- Pred_L0: see semantics for Table 7-13.

The interpretation of `sub_mb_type[mbPartIdx]` for B macroblock types is specified in Table 7-18, where the row for "inferred" specifies values inferred when `sub_mb_type[mbPartIdx]` is not present, and the inferred value "mb_type" specifies that the name of `sub_mb_type[mbPartIdx]` is the same as the name of `mb_type` for this case.

Table 7-18 – Sub-macroblock types in B macroblocks

<code>sub_mb_type[mbPartIdx]</code>	Name of <code>sub_mb_type[mbPartIdx]</code>	NumSubMbPart (<code>sub_mb_type[mbPartIdx]</code>)	SubMbPredMode (<code>sub_mb_type[mbPartIdx]</code>)	SubMbPartWidth (<code>sub_mb_type[mbPartIdx]</code>)	SubMbPartHeight (<code>sub_mb_type[mbPartIdx]</code>)
inferred	mb_type	4	Direct	4	4
0	B_Direct_8x8	4	Direct	4	4
1	B_L0_8x8	1	Pred_L0	8	8
2	B_L1_8x8	1	Pred_L1	8	8
3	B_Bi_8x8	1	BiPred	8	8
4	B_L0_8x4	2	Pred_L0	8	4
5	B_L0_4x8	2	Pred_L0	4	8
6	B_L1_8x4	2	Pred_L1	8	4
7	B_L1_4x8	2	Pred_L1	4	8
8	B_Bi_8x4	2	BiPred	8	4
9	B_Bi_4x8	2	BiPred	4	8
10	B_L0_4x4	4	Pred_L0	4	4
11	B_L1_4x4	4	Pred_L1	4	4
12	B_Bi_4x4	4	BiPred	4	4

The following semantics are assigned to the sub-macroblock types in Table 7-18:

- B_Skip and B_Direct_16x16: no motion vector differences or reference indices are present for the sub-macroblock in the bitstream. The functions `SubMbPartWidth()` and `SubMbPartHeight()` are used in the derivation process for motion vectors and reference frame indices in subclause 8.4.1 for direct mode prediction.
- B_Direct_8x8: no motion vector differences or reference indices are present for the sub-macroblock in the bitstream. The functions `SubMbPartWidth(B_Direct_8x8)` and `SubMbPartHeight(B_Direct_8x8)` are used in the derivation process for motion vectors and reference frame indices in subclause 8.4.1 for direct mode prediction.
- B_X_MxN, with X being replaced by L0, L1, or Bi, and MxN being replaced by 8x8, 8x4, 4x8 or 4x4: the samples of the sub-macroblock are predicted using one luma partition of size MxN equal to 8x8, or the samples of the sub-macroblock are predicted using two luma partitions of size MxN equal to 8x4, or the samples of the sub-macroblock are predicted using two luma partitions of size MxN equal to 4x8, or the samples of the sub-macroblock are predicted using four luma partitions of size MxN equal to 4x4, and associated chroma samples, respectively. All sub-macroblock partitions share the same reference index. For an MxN sub-macroblock partition in a sub-macroblock with `sub_mb_type` being B_X_MxN with X being replaced by either L0 or L1, one motion vector difference is present in the bitstream. For an MxN sub-macroblock partition in a sub-macroblock with `sub_mb_type` being B_Bi_MxN, two motion vector difference are present in the bitstream.

The following semantics are assigned to the sub-macroblock prediction modes (SubMbPredMode()) in Table 7-18.

- Direct: see semantics for Table 7-14.
- Pred_L0: see semantics for Table 7-13.
- Pred_L1: see semantics for Table 7-14.
- BiPred: see semantics for Table 7-14.

ref_idx_l0[mbPartIdx] has the same semantics as ref_idx_l0 in subclause 7.4.5.1.

ref_idx_l1[mbPartIdx] has the same semantics as ref_idx_l1 in subclause 7.4.5.1.

mvd_l0[mbPartIdx][subMbPartIdx][compIdx] has the same semantics as mvd_l0 in subclause 7.4.5.1, except that it is applied to the sub-macroblock partition index with subMbPartIdx. The indices mbPartIdx and subMbPartIdx specify to which macroblock partition and sub-macroblock partition mvd_l0 is assigned.

mvd_l1[mbPartIdx][subMbPartIdx][compIdx] has the same semantics as mvd_l1 in subclause 7.4.5.1.

7.4.5.3 Residual data semantics

The syntax structure residual_block(), which is used for parsing the transform coefficient levels, is assigned as follows.

- If entropy_coding_mode_flag is equal to 0, residual_block is set equal to residual_block_cavlc, which is used for parsing the syntax elements for transform coefficient levels.
- Otherwise (entropy_coding_mode_flag is equal to 1), residual_block is set equal to residual_block_cabac, which is used for parsing the syntax elements for transform coefficient levels.

Depending on mb_type, luma or chroma, and chroma format, the syntax structure residual_block(coeffLevel, maxNumCoeff) is used with the arguments coeffLevel, which is a list containing the maxNumCoeff transform coefficient levels that are parsed in residual_block() and maxNumCoeff as follows.

- Depending on MbPartPredMode(mb_type, 0), the following applies.
 - If MbPartPredMode(mb_type, 0) is equal to Intra_16x16, the transform coefficient levels are parsed into the list Intra16x16DCLevel and into the 16 lists Intra16x16ACLevel[i]. Intra16x16DCLevel contains the 16 transform coefficient levels of the DC transform coefficient levels for each 4x4 luma block. For each of the 16 4x4 luma blocks indexed by i = 0..15, the 15 AC transform coefficients levels of the i-th block are parsed into the i-th list Intra16x16ACLevel[i].
 - Otherwise (MbPartPredMode(mb_type, 0) is not equal to Intra_16x16), the following applies.
 - If transform_size_8x8_flag is equal to 0, for each of the 16 4x4 luma blocks indexed by i = 0..15, the 16 transform coefficient levels of the i-th block are parsed into the i-th list LumaLevel[i].
 - Otherwise (transform_size_8x8_flag is equal to 1), for each of the 4 8x8 luma blocks indexed by i8x8 = 0..3, the following applies.
 - If entropy_coding_mode_flag is equal to 0, first for each of the 4 4x4 luma blocks indexed by i4x4 = 0..3, the 16 transform coefficient levels of the i4x4-th block are parsed into the (i8x8 * 4 + i4x4)-th list LumaLevel[i8x8 * 4 + i4x4]. Then, the 64 transform coefficient levels of the i8x8-th 8x8 luma block which are indexed by 4 * i + i4x4, where i = 0..15 and i4x4 = 0..3, are derived as LumaLevel8x8[i8x8][4 * i + i4x4] = LumaLevel[i8x8 * 4 + i4x4][i].
- NOTE – The 4x4 luma blocks with luma4x4BlkIdx = i8x8 * 4 + i4x4 containing every fourth transform coefficient level of the corresponding i8x8-th 8x8 luma block with offset i4x4 are assumed to represent spatial locations given by the inverse 4x4 luma block scanning process in subclause 6.4.3.
- Otherwise (entropy_coding_mode_flag is equal to 1), the 64 transform coefficient levels of the i8x8-th block are parsed into the i8x8-th list LumaLevel8x8[i8x8].
 - For each chroma component, indexed by iCbCr = 0..1, the DC transform coefficient levels of the 4 * NumC8x8 4x4 chroma blocks are parsed into the iCbCr-th list ChromaDCLevel[iCbCr].
 - For each of the 4x4 chroma blocks, indexed by i4x4 = 0..3 and i8x8 = 0..NumC8x8 – 1, of each chroma component, indexed by iCbCr = 0..1, the 15 AC transform coefficient levels are parsed into the (i8x8*4 + i4x4)-th list of the iCbCr-th chroma component ChromaACLevel[iCbCr][i8x8*4 + i4x4].

7.4.5.3.1 Residual block CAVLC semantics

The function `TotalCoeff(coeff_token)` that is used in subclause 7.3.5.3.1 returns the number of non-zero transform coefficient levels derived from `coeff_token`.

The function `TrailingOnes(coeff_token)` that is used in subclause 7.3.5.3.1 returns the trailing ones derived from `coeff_token`.

coeff_token specifies the total number of non-zero transform coefficient levels and the number of trailing one transform coefficient levels in a transform coefficient level scan. A trailing one transform coefficient level is one of up to three consecutive non-zero transform coefficient levels having an absolute value equal to 1 at the end of a scan of non-zero transform coefficient levels. The range of `coeff_token` is specified in subclause 9.2.1.

trailing_ones_sign_flag specifies the sign of a trailing one transform coefficient level as follows.

- If `trailing_ones_sign_flag` is equal to 0, the corresponding transform coefficient level is decoded as +1.
- Otherwise (`trailing_ones_sign_flag` equal to 1), the corresponding transform coefficient level is decoded as -1.

level_prefix and **level_suffix** specify the value of a non-zero transform coefficient level. The range of `level_prefix` and `level_suffix` is specified in subclause 9.2.2.

total_zeros specifies the total number of zero-valued transform coefficient levels that are located before the position of the last non-zero transform coefficient level in a scan of transform coefficient levels. The range of `total_zeros` is specified in subclause 9.2.3.

run_before specifies the number of consecutive transform coefficient levels in the scan with zero value before a non-zero valued transform coefficient level. The range of `run_before` is specified in subclause 9.2.3.

`coeffLevel` contains `maxNumCoeff` transform coefficient levels for the current list of transform coefficient levels.

7.4.5.3.2 Residual block CABAC semantics

coded_block_flag specifies whether the block contains non-zero transform coefficient levels as follows.

- If `coded_block_flag` is equal to 0, the block contains no non-zero transform coefficient levels.
- Otherwise (`coded_block_flag` is equal to 1), the block contains at least one non-zero transform coefficient level.

significant_coeff_flag[i] specifies whether the transform coefficient level at scanning position `i` is non-zero as follows.

- If `significant_coeff_flag[i]` is equal to 0, the transform coefficient level at scanning position `i` is set equal to 0;
- Otherwise (`significant_coeff_flag[i]` is equal to 1), the transform coefficient level at scanning position `i` has a non-zero value.

last_significant_coeff_flag[i] specifies for the scanning position `i` whether there are non-zero transform coefficient levels for subsequent scanning positions `i + 1` to `maxNumCoeff - 1` as follows.

- If `last_significant_coeff_flag[i]` is equal to 1, all following transform coefficient levels (in scanning order) of the block have value equal to 0.
- Otherwise (`last_significant_coeff_flag[i]` is equal to 0), there are further non-zero transform coefficient levels along the scanning path.

coeff_abs_level_minus1[i] is the absolute value of a transform coefficient level minus 1. The value of `coeff_abs_level_minus1` is constrained by the limits in subclause 8.5.

coeff_sign_flag[i] specifies the sign of a transform coefficient level as follows.

- If `coeff_sign_flag` is equal to 0, the corresponding transform coefficient level has a positive value.
- Otherwise (`coeff_sign_flag` is equal to 1), the corresponding transform coefficient level has a negative value.

`coeffLevel` contains `maxNumCoeff` transform coefficient levels for the current list of transform coefficient levels.

8 Decoding process

Outputs of this process are decoded samples of the current picture (sometimes referred to by the variable `CurrPic`).

This clause describes the decoding process, given syntax elements and upper-case variables from clause 7.

The decoding process is specified such that all decoders shall produce numerically identical results. Any decoding process that produces identical results to the process described here conforms to the decoding process requirements of this Recommendation | International Standard.

Each picture referred to in this clause is a primary picture. Each slice referred to in this clause is a slice of a primary picture. Each slice data partition referred to in this clause is a slice data partition of a primary picture.

An overview of the decoding process is given as follows.

- The decoding of NAL units is specified in subclause 8.1.
- The processes in subclause 8.2 specify decoding processes using syntax elements in the slice layer and above.
 - Variables and functions relating to picture order count are derived in subclause 8.2.1. (only needed to be invoked for one slice of a picture)
 - Variables and functions relating to the macroblock to slice group map are derived in subclause 8.2.2. (only needed to be invoked for one slice of a picture)
 - The method of combining the various partitions when slice data partitioning is used is described in subclause 8.2.3.
 - When the frame_num of the current picture is not equal to PrevRefFrameNum and is not equal to $(\text{PrevRefFrameNum} + 1) \% \text{MaxFrameNum}$, the decoding process for gaps in frame_num is performed according to subclause 8.2.5.2 prior to the decoding of any slices of the current picture.
 - At the beginning of the decoding process for each P, SP, or B slice, the decoding process for reference picture lists construction specified in 8.2.4 performed for derivation of reference picture list 0 (RefPicList0), and when decoding a B slice, reference picture list 1 (RefPicList1).
 - When the current picture is a reference picture and after all slices of the current picture have been decoded, the decoded reference picture marking process in subclause 8.2.5 specifies how the current picture is used in the decoding process of inter prediction in later decoded pictures.
- The processes in subclauses 8.3, 8.4, 8.5, 8.6, and 8.7 specify decoding processes using syntax elements in the macroblock layer and above.
 - The intra prediction process for I and SI macroblocks, except for I_PCM macroblocks as specified in subclause 8.3, has intra prediction samples as its output. For I_PCM macroblocks subclause 8.3 directly specifies a picture construction process. The output are the constructed samples prior to the deblocking filter process.
 - The inter prediction process for P and B macroblocks is specified in subclause 8.4 with inter prediction samples being the output.
 - The transform coefficient decoding process and picture construction process prior to deblocking filter process are specified in subclause 8.5. That process derives samples for I and B macroblocks and for P macroblocks in P slices. The output are constructed samples prior to the deblocking filter process.
 - The decoding process for P macroblocks in SP slices or SI macroblocks is specified in subclause 8.6. That process derives samples for P macroblocks in SP slices and for SI macroblocks. The output are constructed samples prior to the deblocking filter process.
 - The constructed samples prior to the deblocking filter process that are next to the edges of blocks and macroblocks are processed by a deblocking filter as specified in subclause 8.7 with the output being the decoded samples.

8.1 NAL unit decoding process

Inputs to this process are NAL units.

Outputs of this process are the RBSP syntax structures encapsulated within the NAL units.

The decoding process for each NAL unit extracts the RBSP syntax structure from the NAL unit and then operates the decoding processes specified for the RBSP syntax structure in the NAL unit as follows.

Subclause 8.2 describes the decoding process for NAL units with nal_unit_type equal to 1 through 5.

Subclauses 8.3 describes the decoding process for a macroblock or part of a macroblock coded in NAL units with nal_unit_type equal to 1, 2, and 5.

Subclause 8.4 describes the decoding process for a macroblock or part of a macroblock coded in NAL units with nal_unit_type equal to 1 and 2.

Subclause 8.5 describes the decoding process for a macroblock or part of a macroblock coded in NAL units with nal_unit_type equal to 1 and 3 to 5.

Subclause 8.6 describes the decoding process for a macroblock or part of a macroblock coded in NAL units with nal_unit_type equal to 1 and 3 to 5.

Subclause 8.7 describes the decoding process for a macroblock or part of a macroblock coded in NAL units with nal_unit_type equal to 1 to 5.

NAL units with nal_unit_type equal to 7 and 8 contain sequence parameter sets and picture parameter sets, respectively. Picture parameter sets are used in the decoding processes of other NAL units as determined by reference to a picture parameter set within the slice headers of each picture. Sequence parameter sets are used in the decoding processes of other NAL units as determined by reference to a sequence parameter set within the picture parameter sets of each sequence.

No normative decoding process is specified for NAL units with nal_unit_type equal to 6, 9, 10, 11, and 12.

8.2 Slice decoding process

8.2.1 Decoding process for picture order count

Outputs of this process are TopFieldOrderCnt (if applicable) and BottomFieldOrderCnt (if applicable).

Picture order counts are used to determine initial picture orderings for reference pictures in the decoding of B slices (see subclauses 8.2.4.2.3 and 8.2.4.2.4), to represent picture order differences between frames or fields for motion vector derivation in temporal direct mode (see subclause 8.4.1.2.3), for implicit mode weighted prediction in B slices (see subclause 8.4.2.3.2), and for decoder conformance checking (see subclause C.4).

Picture order count information is derived for every frame, field (whether decoded from a coded field or as a part of a decoded frame), or complementary field pair as follows:

- Each coded frame is associated with two picture order counts, called TopFieldOrderCnt and BottomFieldOrderCnt for its top field and bottom field, respectively.
- Each coded field is associated with a picture order count, called TopFieldOrderCnt for a coded top field and BottomFieldOrderCnt for a bottom field.
- Each complementary field pair is associated with two picture order counts, which are the TopFieldOrderCnt for its coded top field and the BottomFieldOrderCnt for its coded bottom field, respectively.

TopFieldOrderCnt and BottomFieldOrderCnt indicate the picture order of the corresponding top field or bottom field relative to the first output field of the previous IDR picture or the previous reference picture including a memory_management_control_operation equal to 5 in decoding order.

TopFieldOrderCnt and BottomFieldOrderCnt are derived by invoking one of the decoding processes for picture order count type 0, 1, and 2 in subclauses 8.2.1.1, 8.2.1.2, and 8.2.1.3, respectively. When the current picture includes a memory management control operation equal to 5, after the decoding of the current picture, tempPicOrderCnt is set equal to PicOrderCnt(CurrPic), TopFieldOrderCnt of the current picture (if any) is set equal to TopFieldOrderCnt - tempPicOrderCnt, and BottomFieldOrderCnt of the current picture (if any) is set equal to BottomFieldOrderCnt - tempPicOrderCnt.

The bitstream shall not contain data that results in $\text{Min}(\text{TopFieldOrderCnt}, \text{BottomFieldOrderCnt})$ not equal to 0 for a coded IDR frame, TopFieldOrderCnt not equal to 0 for a coded IDR top field, or BottomFieldOrderCnt not equal to 0 for a coded IDR bottom field. Thus, at least one of TopFieldOrderCnt and BottomFieldOrderCnt shall be equal to 0 for the fields of a coded IDR frame.

When the current picture is not an IDR picture, the following applies.

- Consider the list variable listD containing as elements the TopFieldOrderCnt and BottomFieldOrderCnt values associated with the list of pictures including all of the following
 - the first picture in the list is the previous picture of any of the following types
 - an IDR picture
 - a picture containing a memory_management_control_operation equal to 5
 - the following additional pictures.

- If `pic_order_cnt_type` is equal to 0, all other pictures that follow in decoding order after the first picture in the list and are not "non-existing" frames inferred by the decoding process for gaps in `frame_num` specified in subclause 8.2.5.2 and either precede the current picture in decoding order or are the current picture. When `pic_order_cnt_type` is equal to 0 and the current picture is not a "non-existing" frame inferred by the decoding process for gaps in `frame_num` specified in subclause 8.2.5.2, the current picture is included in `listD` prior to the invoking of the decoded reference picture marking process.

Otherwise (`pic_order_cnt_type` is not equal to 0), all other pictures that follow in decoding order after the first picture in the list and either precede the current picture in decoding order or are the current picture. When `pic_order_cnt_type` is not equal to 0, the current picture is included in `listD` prior to the invoking of the decoded reference picture marking process.

- Consider the list variable `listO` which contains the elements of `listD` sorted in ascending order. `listO` shall not contain any of the following.
 - a pair of `TopFieldOrderCnt` and `BottomFieldOrderCnt` for a frame or complementary field pair that are not at consecutive positions in `listO`.
 - a `TopFieldOrderCnt` that has a value equal to another `TopFieldOrderCnt`.
 - a `BottomFieldOrderCnt` that has a value equal to another `BottomFieldOrderCnt`.
 - a `BottomFieldOrderCnt` that has a value equal to a `TopFieldOrderCnt` unless the `BottomFieldOrderCnt` and `TopFieldOrderCnt` belong to the same coded frame or complementary field pair.

The bitstream shall not contain data that results in values of `TopFieldOrderCnt`, `BottomFieldOrderCnt`, `PicOrderCntMsb`, or `FrameNumOffset` used in the decoding process as specified in subclauses 8.2.1.1 to 8.2.1.3 that exceed the range of values from -2^{31} to $2^{31}-1$, inclusive.

The function `PicOrderCnt(picX)` is specified as follows:

```

if( picX is a frame or a complementary field pair )
    PicOrderCnt( picX ) = Min( TopFieldOrderCnt, BottomFieldOrderCnt ) of the frame or complementary field
    pair picX
else if( picX is a top field )
    PicOrderCnt( picX ) = TopFieldOrderCnt of field picX
else if( picX is a bottom field )
    PicOrderCnt( picX ) = BottomFieldOrderCnt of field picX

```

(8-1)

Then `DiffPicOrderCnt(picA, picB)` is specified as follows:

$$\text{DiffPicOrderCnt}(\text{picA}, \text{picB}) = \text{PicOrderCnt}(\text{picA}) - \text{PicOrderCnt}(\text{picB})$$

(8-2)

The bitstream shall not contain data that results in values of `DiffPicOrderCnt(picA, picB)` used in the decoding process that exceed the range of -2^{15} to $2^{15} - 1$, inclusive.

NOTE 1 – Let *X* be the current picture and *Y* and *Z* be two other pictures in the same sequence, *Y* and *Z* are considered to be in the same output order direction from *X* when both `DiffPicOrderCnt(X, Y)` and `DiffPicOrderCnt(X, Z)` are positive or both are negative.

NOTE 2 – Many applications assign `PicOrderCnt(X)` proportional to the sampling time of the picture *X* relative to the sampling time of an IDR picture.

When the current picture includes a `memory_management_control_operation` equal to 5, `PicOrderCnt(CurrPic)` shall be greater than `PicOrderCnt(any other picture in listD)`.

8.2.1.1 Decoding process for picture order count type 0

This process is invoked when `pic_order_cnt_type` is equal to 0.

Input to this process is `PicOrderCntMsb` of the previous reference picture in decoding order as specified in this subclause.

Outputs of this process are either or both `TopFieldOrderCnt` or `BottomFieldOrderCnt`.

The variables `prevPicOrderCntMsb` and `prevPicOrderCntLsb` are derived as follows.

- If the current picture is an IDR picture, `prevPicOrderCntMsb` is set equal to 0 and `prevPicOrderCntLsb` is set equal to 0.
- Otherwise (the current picture is not an IDR picture), the following applies.

- If the previous reference picture in decoding order included a memory_management_control_operation equal to 5, the following applies.
 - If the previous reference picture in decoding order is not a bottom field, prevPicOrderCntMsb is set equal to 0 and prevPicOrderCntLsb is set equal to the value of TopFieldOrderCnt for the previous reference picture in decoding order.
 - Otherwise (the previous reference picture in decoding order is a bottom field), prevPicOrderCntMsb is set equal to 0 and prevPicOrderCntLsb is set equal to 0.
- Otherwise (the previous reference picture in decoding order did not include a memory_management_control_operation equal to 5), prevPicOrderCntMsb is set equal to PicOrderCntMsb of the previous reference picture in decoding order and prevPicOrderCntLsb is set equal to the value of pic_order_cnt_lsb of the previous reference picture in decoding order.

PicOrderCntMsb of the current picture is derived as follows:

```

if( ( pic_order_cnt_lsb < prevPicOrderCntLsb ) &&
    ( ( prevPicOrderCntLsb - pic_order_cnt_lsb ) >= ( MaxPicOrderCntLsb / 2 ) ) )
    PicOrderCntMsb = prevPicOrderCntMsb + MaxPicOrderCntLsb
else if( ( pic_order_cnt_lsb > prevPicOrderCntLsb ) &&
    ( ( pic_order_cnt_lsb - prevPicOrderCntLsb ) > ( MaxPicOrderCntLsb / 2 ) ) )
    PicOrderCntMsb = prevPicOrderCntMsb - MaxPicOrderCntLsb
else
    PicOrderCntMsb = prevPicOrderCntMsb

```

(8-3)

When the current picture is not a bottom field, TopFieldOrderCnt is derived as follows:

```

if( !field_pic_flag || !bottom_field_flag )
    TopFieldOrderCnt = PicOrderCntMsb + pic_order_cnt_lsb

```

(8-4)

When the current picture is not a top field, BottomFieldOrderCnt is derived as follows:

```

if( !field_pic_flag )
    BottomFieldOrderCnt = TopFieldOrderCnt + delta_pic_order_cnt_bottom
else if( bottom_field_flag )
    BottomFieldOrderCnt = PicOrderCntMsb + pic_order_cnt_lsb

```

(8-5)

8.2.1.2 Decoding process for picture order count type 1

This process is invoked when pic_order_cnt_type is equal to 1.

Input to this process is FrameNumOffset of the previous picture in decoding order as specified in this subclause.

Outputs of this process are either or both TopFieldOrderCnt or BottomFieldOrderCnt.

The values of TopFieldOrderCnt and BottomFieldOrderCnt are derived as specified in this subclause. Let prevFrameNum be equal to the frame_num of the previous picture in decoding order.

When the current picture is not an IDR picture, the variable prevFrameNumOffset is derived as follows.

- If the previous picture in decoding order included a memory_management_control_operation equal to 5, prevFrameNumOffset is set equal to 0.
 - Otherwise (the previous picture in decoding order did not include a memory_management_control_operation equal to 5), prevFrameNumOffset is set equal to the value of FrameNumOffset of the previous picture in decoding order.
- NOTE – When gaps_in_frame_num_value_allowed_flag is equal to 1, the previous picture in decoding order may be a "non-existing" frame inferred by the decoding process for gaps in frame_num specified in subclause 8.2.5.2.

The derivation proceeds in the following ordered steps.

1. The variable FrameNumOffset is derived as follows:

```

if( nal_unit_type == 5 )
    FrameNumOffset = 0
else if( prevFrameNum > frame_num )
    FrameNumOffset = prevFrameNumOffset + MaxFrameNum

```

(8-6)

```

else
    FrameNumOffset = prevFrameNumOffset

```

2. The variable `absFrameNum` is derived as follows:

```

if( num_ref_frames_in_pic_order_cnt_cycle != 0 )
    absFrameNum = FrameNumOffset + frame_num
else
    absFrameNum = 0
if( nal_ref_idc == 0 && absFrameNum > 0 )
    absFrameNum = absFrameNum - 1

```

(8-7)

3. When `absFrameNum > 0`, `picOrderCntCycleCnt` and `frameNumInPicOrderCntCycle` are derived as follows:

```

if( absFrameNum > 0 ) {
    picOrderCntCycleCnt = ( absFrameNum - 1 ) / num_ref_frames_in_pic_order_cnt_cycle
    frameNumInPicOrderCntCycle = ( absFrameNum - 1 ) % num_ref_frames_in_pic_order_cnt_cycle
}

```

(8-8)

4. The variable `expectedDeltaPerPicOrderCntCycle` is derived as follows:

```

expectedDeltaPerPicOrderCntCycle = 0
for( i = 0; i < num_ref_frames_in_pic_order_cnt_cycle; i++ )
    expectedDeltaPerPicOrderCntCycle += offset_for_ref_frame[ i ]

```

(8-9)

5. The variable `expectedPicOrderCnt` is derived as follows:

```

if( absFrameNum > 0 ){
    expectedPicOrderCnt = picOrderCntCycleCnt * expectedDeltaPerPicOrderCntCycle
    for( i = 0; i <= frameNumInPicOrderCntCycle; i++ )
        expectedPicOrderCnt = expectedPicOrderCnt + offset_for_ref_frame[ i ]
} else
    expectedPicOrderCnt = 0
if( nal_ref_idc == 0 )
    expectedPicOrderCnt = expectedPicOrderCnt + offset_for_non_ref_pic

```

(8-10)

6. The variables `TopFieldOrderCnt` or `BottomFieldOrderCnt` are derived as follows:

```

if( !field_pic_flag ) {
    TopFieldOrderCnt = expectedPicOrderCnt + delta_pic_order_cnt[ 0 ]
    BottomFieldOrderCnt = TopFieldOrderCnt +
        offset_for_top_to_bottom_field + delta_pic_order_cnt[ 1 ]
} else if( !bottom_field_flag )
    TopFieldOrderCnt = expectedPicOrderCnt + delta_pic_order_cnt[ 0 ]
else
    BottomFieldOrderCnt = expectedPicOrderCnt + offset_for_top_to_bottom_field + delta_pic_order_cnt[ 0 ]

```

(8-11)

8.2.1.3 Decoding process for picture order count type 2

This process is invoked when `pic_order_cnt_type` is equal to 2.

Outputs of this process are either or both `TopFieldOrderCnt` or `BottomFieldOrderCnt`.

Let `prevFrameNum` be equal to the `frame_num` of the previous picture in decoding order.

When the current picture is not an IDR picture, the variable `prevFrameNumOffset` is derived as follows.

- If the previous picture in decoding order included a `memory_management_control_operation` equal to 5, `prevFrameNumOffset` is set equal to 0.
- Otherwise (the previous picture in decoding order did not include a `memory_management_control_operation` equal to 5), `prevFrameNumOffset` is set equal to the value of `FrameNumOffset` of the previous picture in decoding order.

NOTE 1 – When `gaps_in_frame_num_value_allowed_flag` is equal to 1, the previous picture in decoding order may be a "non-existing" frame inferred by the decoding process for gaps in `frame_num` specified in subclause 8.2.5.2.

The variable `FrameNumOffset` is derived as follows.

```

if( nal_unit_type == 5 )
    FrameNumOffset = 0
else if( prevFrameNum > frame_num )
    FrameNumOffset = prevFrameNumOffset + MaxFrameNum
else
    FrameNumOffset = prevFrameNumOffset

```

(8-12)

The variable `tempPicOrderCnt` is derived as follows:

```

if( nal_unit_type == 5 )
    tempPicOrderCnt = 0
else if( nal_ref_idc == 0 )
    tempPicOrderCnt = 2 * ( FrameNumOffset + frame_num ) - 1
else
    tempPicOrderCnt = 2 * ( FrameNumOffset + frame_num )

```

(8-13)

The variables `TopFieldOrderCnt` or `BottomFieldOrderCnt` are derived as follows:

```

if( !field_pic_flag ) {
    TopFieldOrderCnt = tempPicOrderCnt
    BottomFieldOrderCnt = tempPicOrderCnt
} else if( bottom_field_flag )
    BottomFieldOrderCnt = tempPicOrderCnt
else
    TopFieldOrderCnt = tempPicOrderCnt

```

(8-14)

NOTE 2 – Picture order count type 2 cannot be used in a coded video sequence that contains consecutive non-reference pictures that would result in more than one of these pictures having the same value of `TopFieldOrderCnt` or more than one of these pictures having the same value of `BottomFieldOrderCnt`.

NOTE 3 – Picture order count type 2 results in an output order that is the same as the decoding order.

8.2.2 Decoding process for macroblock to slice group map

Inputs to this process are the active picture parameter set and the slice header of the slice to be decoded.

Output of this process is a macroblock to slice group map `MbToSliceGroupMap`.

This process is invoked at the start of every slice.

NOTE – The output of this process is equal for all slices of a picture.

When `num_slice_groups_minus1` is equal to 1 and `slice_group_map_type` is equal to 3, 4, or 5, slice groups 0 and 1 have a size and shape determined by `slice_group_change_direction_flag` as shown in Table 8-1 and specified in subclauses 8.2.2.4 to 8.2.2.6.

Table 8-1 – Refined slice group map type

slice_group_map_type	slice_group_change_direction_flag	refined slice group map type
3	0	Box-out clockwise
3	1	Box-out counter-clockwise
4	0	Raster scan
4	1	Reverse raster scan
5	0	Wipe right
5	1	Wipe left

In such a case, MapUnitsInSliceGroup0 slice group map units in the specified growth order are allocated for slice group 0 and the remaining PicSizeInMapUnits – MapUnitsInSliceGroup0 slice group map units of the picture are allocated for slice group 1.

When num_slice_groups_minus1 is equal to 1 and slice_group_map_type is equal to 4 or 5, the variable sizeOfUpperLeftGroup is defined as follows:

$$\text{sizeOfUpperLeftGroup} = (\text{slice_group_change_direction_flag} ? (\text{PicSizeInMapUnits} - \text{MapUnitsInSliceGroup0}) : \text{MapUnitsInSliceGroup0}) \quad (8-15)$$

The variable mapUnitToSliceGroupMap is derived as follows.

- If num_slice_groups_minus1 is equal to 0, the map unit to slice group map is generated for all i ranging from 0 to PicSizeInMapUnits – 1, inclusive, as specified by:

$$\text{mapUnitToSliceGroupMap}[i] = 0 \quad (8-16)$$

- Otherwise (num_slice_groups_minus1 is not equal to 0), mapUnitToSliceGroupMap is derived as follows.
 - If slice_group_map_type is equal to 0, the derivation of mapUnitToSliceGroupMap as specified in subclause 8.2.2.1 applies.
 - Otherwise, if slice_group_map_type is equal to 1, the derivation of mapUnitToSliceGroupMap as specified in subclause 8.2.2.2 applies.
 - Otherwise, if slice_group_map_type is equal to 2, the derivation of mapUnitToSliceGroupMap as specified in subclause 8.2.2.3 applies.
 - Otherwise, if slice_group_map_type is equal to 3, the derivation of mapUnitToSliceGroupMap as specified in subclause 8.2.2.4 applies.
 - Otherwise, if slice_group_map_type is equal to 4, the derivation of mapUnitToSliceGroupMap as specified in subclause 8.2.2.5 applies.
 - Otherwise, if slice_group_map_type is equal to 5, the derivation of mapUnitToSliceGroupMap as specified in subclause 8.2.2.6 applies.
 - Otherwise (slice_group_map_type is equal to 6), the derivation of mapUnitToSliceGroupMap as specified in subclause 8.2.2.7 applies.

After derivation of the mapUnitToSliceGroupMap, the process specified in subclause 8.2.2.8 is invoked to convert the map unit to slice group map mapUnitToSliceGroupMap to the macroblock to slice group map MbToSliceGroupMap. After derivation of the macroblock to slice group map as specified in subclause 8.2.2.8, the function NextMbAddress(n) is defined as the value of the variable nextMbAddress derived as specified by:

$$\begin{aligned} i &= n + 1 \\ \text{while}(i < \text{PicSizeInMbs} \ \&\& \ \text{MbToSliceGroupMap}[i] \neq \text{MbToSliceGroupMap}[n]) \\ &\quad i++; \\ \text{nextMbAddress} &= i \end{aligned} \quad (8-17)$$

8.2.2.1 Specification for interleaved slice group map type

The specifications in this subclause apply when slice_group_map_type is equal to 0.

The map unit to slice group map is generated as specified by:

$$\begin{aligned} i &= 0 \\ \text{do} \\ &\quad \text{for}(iGroup = 0; iGroup \leq \text{num_slice_groups_minus1} \ \&\& \ i < \text{PicSizeInMapUnits}; \\ &\quad \quad i += \text{run_length_minus1}[iGroup++] + 1) \\ &\quad \quad \text{for}(j = 0; j \leq \text{run_length_minus1}[iGroup] \ \&\& \ i + j < \text{PicSizeInMapUnits}; j++) \\ &\quad \quad \quad \text{mapUnitToSliceGroupMap}[i + j] = iGroup \\ \text{while}(i < \text{PicSizeInMapUnits}) \end{aligned} \quad (8-18)$$

8.2.2.2 Specification for dispersed slice group map type

The specifications in this subclause apply when slice_group_map_type is equal to 1.

The map unit to slice group map is generated as specified by:

```
for( i = 0; i < PicSizeInMapUnits; i++ )
    mapUnitToSliceGroupMap[ i ] = ( ( i % PicWidthInMbs ) +
        ( ( i / PicWidthInMbs ) * ( num_slice_groups_minus1 + 1 ) ) / 2 )
        % ( num_slice_groups_minus1 + 1 )
```

(8-19)

8.2.2.3 Specification for foreground with left-over slice group map type

The specifications in this subclause apply when slice_group_map_type is equal to 2.

The map unit to slice group map is generated as specified by:

```
for( i = 0; i < PicSizeInMapUnits; i++ )
    mapUnitToSliceGroupMap[ i ] = num_slice_groups_minus1
for( iGroup = num_slice_groups_minus1 - 1; iGroup >= 0; iGroup-- ) {
    yTopLeft = top_left[ iGroup ] / PicWidthInMbs
    xTopLeft = top_left[ iGroup ] % PicWidthInMbs
    yBottomRight = bottom_right[ iGroup ] / PicWidthInMbs
    xBottomRight = bottom_right[ iGroup ] % PicWidthInMbs
    for( y = yTopLeft; y <= yBottomRight; y++ )
        for( x = xTopLeft; x <= xBottomRight; x++ )
            mapUnitToSliceGroupMap[ y * PicWidthInMbs + x ] = iGroup
}
```

(8-20)

NOTE – The rectangles may overlap. Slice group 0 contains the macroblocks that are within the rectangle specified by top_left[0] and bottom_right[0]. A slice group having slice group ID greater than 0 and less than num_slice_groups_minus1 contains the macroblocks that are within the specified rectangle for that slice group that are not within the rectangle specified for any slice group having a smaller slice group ID. The slice group with slice group ID equal to num_slice_groups_minus1 contains the macroblocks that are not in the other slice groups.

8.2.2.4 Specification for box-out slice group map types

The specifications in this subclause apply when slice_group_map_type is equal to 3.

The map unit to slice group map is generated as specified by:

```
for( i = 0; i < PicSizeInMapUnits; i++ )
    mapUnitToSliceGroupMap[ i ] = 1
x = ( PicWidthInMbs - slice_group_change_direction_flag ) / 2
y = ( PicHeightInMapUnits - slice_group_change_direction_flag ) / 2
( leftBound, topBound ) = ( x, y )
( rightBound, bottomBound ) = ( x, y )
( xDir, yDir ) = ( slice_group_change_direction_flag - 1, slice_group_change_direction_flag )
for( k = 0; k < MapUnitsInSliceGroup0; k += mapUnitVacant ) {
    mapUnitVacant = ( mapUnitToSliceGroupMap[ y * PicWidthInMbs + x ] == 1 )
    if( mapUnitVacant )
        mapUnitToSliceGroupMap[ y * PicWidthInMbs + x ] = 0
    if( xDir == -1 && x == leftBound ) {
        leftBound = Max( leftBound - 1, 0 )
        x = leftBound
        ( xDir, yDir ) = ( 0, 2 * slice_group_change_direction_flag - 1 )
    } else if( xDir == 1 && x == rightBound ) {
        rightBound = Min( rightBound + 1, PicWidthInMbs - 1 )
        x = rightBound
        ( xDir, yDir ) = ( 0, 1 - 2 * slice_group_change_direction_flag )
    } else if( yDir == -1 && y == topBound ) {
        topBound = Max( topBound - 1, 0 )
        y = topBound
        ( xDir, yDir ) = ( 1 - 2 * slice_group_change_direction_flag, 0 )
    } else if( yDir == 1 && y == bottomBound ) {
        bottomBound = Min( bottomBound + 1, PicHeightInMapUnits - 1 )
        y = bottomBound
        ( xDir, yDir ) = ( 2 * slice_group_change_direction_flag - 1, 0 )
    } else
```

(8-21)

```

        ( x, y ) = ( x + xDir, y + yDir )
    }

```

8.2.2.5 Specification for raster scan slice group map types

The specifications in this subclause apply when slice_group_map_type is equal to 4.

The map unit to slice group map is generated as specified by:

```

for( i = 0; i < PicSizeInMapUnits; i++ )
    if( i < sizeOfUpperLeftGroup )
        mapUnitToSliceGroupMap[ i ] = slice_group_change_direction_flag
    else
        mapUnitToSliceGroupMap[ i ] = 1 - slice_group_change_direction_flag

```

(8-22)

8.2.2.6 Specification for wipe slice group map types

The specifications in this subclause apply when slice_group_map_type is equal to 5.

The map unit to slice group map is generated as specified by:

```

k = 0;
for( j = 0; j < PicWidthInMbs; j++ )
    for( i = 0; i < PicHeightInMapUnits; i++ )
        if( k++ < sizeOfUpperLeftGroup )
            mapUnitToSliceGroupMap[ i * PicWidthInMbs + j ] = slice_group_change_direction_flag
        else
            mapUnitToSliceGroupMap[ i * PicWidthInMbs + j ] = 1 - slice_group_change_direction_flag

```

(8-23)

8.2.2.7 Specification for explicit slice group map type

The specifications in this subclause apply when slice_group_map_type is equal to 6.

The map unit to slice group map is generated as specified by:

$$\text{mapUnitToSliceGroupMap}[i] = \text{slice_group_id}[i] \quad (8-24)$$

for all i ranging from 0 to PicSizeInMapUnits – 1, inclusive.

8.2.2.8 Specification for conversion of map unit to slice group map to macroblock to slice group map

For each value of i ranging from 0 to PicSizeInMbs – 1, inclusive, the macroblock to slice group map is specified as follows.

- If frame_mbs_only_flag is equal to 1 or field_pic_flag is equal to 1, the macroblock to slice group map is specified by:

$$\text{MbToSliceGroupMap}[i] = \text{mapUnitToSliceGroupMap}[i] \quad (8-25)$$

- Otherwise, if MbaffFrameFlag is equal to 1, the macroblock to slice group map is specified by:

$$\text{MbToSliceGroupMap}[i] = \text{mapUnitToSliceGroupMap}[i / 2] \quad (8-26)$$

- Otherwise (frame_mbs_only_flag is equal to 0 and mb_adaptive_frame_field_flag is equal to 0 and field_pic_flag is equal to 0), the macroblock to slice group map is specified by:

$$\begin{aligned} \text{MbToSliceGroupMap}[i] = \text{mapUnitToSliceGroupMap}[(i / (2 * \text{PicWidthInMbs})) * \text{PicWidthInMbs} \\ + (i \% \text{PicWidthInMbs})] \end{aligned} \quad (8-27)$$

8.2.3 Decoding process for slice data partitioning

Inputs to this process are

- a slice data partition A layer RBSP,

- when syntax elements of category 3 are present in the slice data, a slice data partition B layer RBSP having the same slice_id as in the slice data partition A layer RBSP, and
- when syntax elements of category 4 are present in the slice data, a slice data partition C layer RBSP having the same slice_id as in the slice data partition A layer RBSP.

NOTE 1 – The slice data partition B layer RBSP and slice data partition C layer RBSP need not be present.

Output of this process is a coded slice.

When slice data partitioning is not used, coded slices are represented by a slice layer without partitioning RBSP that contains a slice header followed by a slice data syntax structure that contains all the syntax elements of categories 2, 3, and 4 (see category column in subclause 7.3) of the macroblock data for the macroblocks of the slice.

When slice data partitioning is used, the macroblock data of a slice is partitioned into one to three partitions contained in separate NAL units. Partition A contains a slice data partition A header, and all syntax elements of category 2. Partition B, when present, contains a slice data partition B header and all syntax elements of category 3. Partition C, when present, contains a slice data partition C header and all syntax elements of category 4.

When slice data partitioning is used, the syntax elements of each category are parsed from a separate NAL unit, which need not be present when no symbols of the respective category exist. The decoding process shall process the slice data partitions of a coded slice in a manner equivalent to processing a corresponding slice layer without partitioning RBSP by extracting each syntax element from the slice data partition in which the syntax element appears depending on the slice data partition assignment in the syntax tables in subclause 7.3.

NOTE 2 – Syntax elements of category 3 are relevant to the decoding of residual data of I and SI macroblock types. Syntax elements of category 4 are relevant to the decoding of residual data of P and B macroblock types. Category 2 encompasses all other syntax elements related to the decoding of macroblocks, and their information is often denoted as header information. The slice data partition A header contains all the syntax elements of the slice header, and additionally a slice_id that are used to associate the slice data partitions B and C with the slice data partition A. The slice data partition B and C headers contain the slice_id syntax element that establishes their association with the slice data partition A of the slice.

8.2.4 Decoding process for reference picture lists construction

This process is invoked at the beginning of decoding of each P, SP, or B slice.

Decoded reference pictures are marked as "used for short-term reference" or "used for long-term reference" as specified by the bitstream and specified in subclause 8.2.5. Short-term reference pictures are identified by the value of frame_num. Long-term reference pictures are assigned a long-term frame index as specified by the bitstream and specified in subclause 8.2.5.

Subclause 8.2.4.1 is invoked to specify

- the assignment of variables FrameNum, FrameNumWrap, and PicNum to each of the short-term reference pictures, and
- the assignment of variable LongTermPicNum to each of the long-term reference pictures.

Reference pictures are addressed through reference indices as specified in subclause 8.4.2.1. A reference index is an index into a reference picture list. When decoding a P or SP slice, there is a single reference picture list RefPicList0. When decoding a B slice, there is a second independent reference picture list RefPicList1 in addition to RefPicList0.

At the beginning of decoding of each slice, reference picture list RefPicList0, and for B slices RefPicList1, are derived as follows.

- An initial reference picture list RefPicList0 and for B slices RefPicList1 are derived as specified in subclause 8.2.4.2.
- The initial reference picture list RefPicList0 and for B slices RefPicList1 are modified as specified in subclause 8.2.4.3.

NOTE – The reordering process for reference picture lists specified in subclause 8.2.4.3 allows the contents of RefPicList0 and for B slices RefPicList1 to be modified in a flexible fashion. In particular, it is possible for a picture that is currently marked "used for reference" to be inserted into RefPicList0 and for B slices RefPicList1 even when the picture is not in the initial reference picture list derived as specified in subclause 8.2.4.2.

The number of entries in the modified reference picture list RefPicList0 is num_ref_idx_l0_active_minus1 + 1, and for B slices the number of entries in the modified reference picture list RefPicList1 is num_ref_idx_l1_active_minus1 + 1. A reference picture may appear at more than one index in the modified reference picture lists RefPicList0 or RefPicList1.

8.2.4.1 Decoding process for picture numbers

This process is invoked when the decoding process for reference picture lists construction specified in subclause 8.2.4 or the decoded reference picture marking process specified in subclause 8.2.5 is invoked.

The variables `FrameNum`, `FrameNumWrap`, `PicNum`, `LongTermFrameIdx`, and `LongTermPicNum` are used for the initialisation process for reference picture lists in subclause 8.2.4.2, the modification process for reference picture lists in subclause 8.2.4.3, and for the decoded reference picture marking process in subclause 8.2.5.

To each short-term reference picture the variables `FrameNum` and `FrameNumWrap` are assigned as follows. First, `FrameNum` is set equal to the syntax element `frame_num` that has been decoded in the slice header(s) of the corresponding short-term reference picture. Then the variable `FrameNumWrap` is derived as

$$\begin{aligned} &\text{if(FrameNum > frame_num)} \\ &\quad \text{FrameNumWrap} = \text{FrameNum} - \text{MaxFrameNum} \\ &\text{else} \\ &\quad \text{FrameNumWrap} = \text{FrameNum} \end{aligned} \tag{8-28}$$

where the value of `frame_num` used in Equation 8-28 is the `frame_num` in the slice header(s) for the current picture.

Each long-term reference picture has an associated value of `LongTermFrameIdx` (that was assigned to it as specified in subclause 8.2.5).

To each short-term reference picture a variable `PicNum` is assigned, and to each long-term reference picture a variable `LongTermPicNum` is assigned. The values of these variables depend on the value of `field_pic_flag` and `bottom_field_flag` for the current picture and they are set as follows.

- If `field_pic_flag` is equal to 0, the following applies.

- For each short-term reference frame or complementary reference field pair:

$$\text{PicNum} = \text{FrameNumWrap} \tag{8-29}$$

- For each long-term reference frame or long-term complementary reference field pair:

$$\text{LongTermPicNum} = \text{LongTermFrameIdx} \tag{8-30}$$

NOTE – When decoding a frame the value of `MbaffFrameFlag` has no influence on the derivations in subclauses 8.2.4.2, 8.2.4.3, and 8.2.5.

- Otherwise (`field_pic_flag` is equal to 1), the following applies.

- For each short-term reference field the following applies.

- If the reference field has the same parity as the current field

$$\text{PicNum} = 2 * \text{FrameNumWrap} + 1 \tag{8-31}$$

- Otherwise (the reference field has the opposite parity of the current field),

$$\text{PicNum} = 2 * \text{FrameNumWrap} \tag{8-32}$$

- For each long-term reference field the following applies.

- If the reference field has the same parity as the current field

$$\text{LongTermPicNum} = 2 * \text{LongTermFrameIdx} + 1 \tag{8-33}$$

- Otherwise (the reference field has the opposite parity of the current field),

$$\text{LongTermPicNum} = 2 * \text{LongTermFrameIdx} \tag{8-34}$$

8.2.4.2 Initialisation process for reference picture lists

This initialisation process is invoked when decoding a P, SP, or B slice header.

RefPicList0 and RefPicList1 have initial entries as specified in subclauses 8.2.4.2.1 through 8.2.4.2.5.

When the number of entries in the initial RefPicList0 or RefPicList1 produced as specified in subclauses 8.2.4.2.1 through 8.2.4.2.5 is greater than $\text{num_ref_idx_l0_active_minus1} + 1$ or $\text{num_ref_idx_l1_active_minus1} + 1$, respectively, the extra entries past position $\text{num_ref_idx_l0_active_minus1}$ or $\text{num_ref_idx_l1_active_minus1}$ are discarded from the initial reference picture list.

When the number of entries in the initial RefPicList0 or RefPicList1 produced as specified in subclauses 8.2.4.2.1 through 8.2.4.2.5 is less than $\text{num_ref_idx_l0_active_minus1} + 1$ or $\text{num_ref_idx_l1_active_minus1} + 1$, respectively, the remaining entries in the initial reference picture list are set equal to "no reference picture".

8.2.4.2.1 Initialisation process for the reference picture list for P and SP slices in frames

This initialisation process is invoked when decoding a P or SP slice in a coded frame.

When this process is invoked, there shall be at least one reference frame or complementary reference field pair that is currently marked as "used for short-term reference" or "used for long-term reference".

The reference picture list RefPicList0 is ordered so that short-term reference frames and short-term complementary reference field pairs have lower indices than long-term reference frames and long-term complementary reference field pairs.

The short-term reference frames and complementary reference field pairs are ordered starting with the frame or complementary field pair with the highest PicNum value and proceeding through in descending order to the frame or complementary field pair with the lowest PicNum value.

The long-term reference frames and complementary reference field pairs are ordered starting with the frame or complementary field pair with the lowest LongTermPicNum value and proceeding through in ascending order to the frame or complementary field pair with the highest LongTermPicNum value.

NOTE – A non-paired reference field is not used for inter prediction for decoding a frame, regardless of the value of MbaffFrameFlag.

For example, when three reference frames are marked as "used for short-term reference" with PicNum equal to 300, 302, and 303 and two reference frames are marked as "used for long-term reference" with LongTermPicNum equal to 0 and 3, the initial index order is:

- RefPicList0[0] is set equal to the short-term reference picture with PicNum = 303,
- RefPicList0[1] is set equal to the short-term reference picture with PicNum = 302,
- RefPicList0[2] is set equal to the short-term reference picture with PicNum = 300,
- RefPicList0[3] is set equal to the long-term reference picture with LongTermPicNum = 0, and
- RefPicList0[4] is set equal to the long-term reference picture with LongTermPicNum = 3.

8.2.4.2.2 Initialisation process for the reference picture list for P and SP slices in fields

This initialisation process is invoked when decoding a P or SP slice in a coded field.

Each field included in the reference picture list RefPicList0 has a separate index in the reference picture list RefPicList0.

NOTE – When decoding a field, there are effectively at least twice as many pictures available for referencing as there would be when decoding a frame at the same position in decoding order.

Two ordered lists of reference frames, refFrameList0ShortTerm and refFrameList0LongTerm, are derived as follows. For purposes of the formation of this list of frames, decoded reference frames, complementary reference field pairs, non-paired reference fields and reference frames in which a single field is marked "used for short-term reference" or "used for long-term reference" are all considered reference frames.

- All frames having one or more fields marked "used for short-term reference" are included in the list of short-term reference frames refFrameList0ShortTerm. When the current field is the second field (in decoding order) of a complementary reference field pair and the first field is marked as "used for short-term reference", the first field is included in the list of short-term reference frames refFrameList0ShortTerm. refFrameList0ShortTerm is ordered starting with the reference frame with the highest FrameNumWrap value and proceeding through in descending order to the reference frame with the lowest FrameNumWrap value.
- All frames having one or more fields marked "used for long-term reference" are included in the list of long-term reference frames refFrameList0LongTerm. When the current field is the second field (in decoding order) of a complementary reference field pair and the first field is marked as "used for long-term reference", the first field is included in the list of long-term reference frames refFrameList0LongTerm. refFrameList0LongTerm is ordered

starting with the reference frame with the lowest LongTermFrameIdx value and proceeding through in ascending order to the reference frame with the highest LongTermFrameIdx value.

The process specified in subclause 8.2.4.2.5 is invoked with refFrameList0ShortTerm and refFrameList0LongTerm given as input and the output is assigned to RefPicList0.

8.2.4.2.3 Initialisation process for reference picture lists for B slices in frames

This initialisation process is invoked when decoding a B slice in a coded frame.

For purposes of the formation of the reference picture lists RefPicList0 and RefPicList1 the term reference entry refers in the following to decoded reference frames or complementary reference field pairs.

When this process is invoked, there shall be at least one reference entry that is currently marked as "used for short-term reference" or "used for long-term reference".

For B slices, the order of short-term reference entries in the reference picture lists RefPicList0 and RefPicList1 depends on output order, as given by PicOrderCnt(). When pic_order_cnt_type is equal to 0, reference pictures that are marked as "non-existing" as specified in subclause 8.2.5.2 are not included in either RefPicList0 or RefPicList1.

NOTE 1 – When gaps_in_frame_num_value_allowed_flag is equal to 1, encoders should use reference picture list reordering to ensure proper operation of the decoding process (particularly when pic_order_cnt_type is equal to 0, in which case PicOrderCnt() is not inferred for "non-existing" frames).

The reference picture list RefPicList0 is ordered such that short-term reference entries have lower indices than long-term reference entries. It is ordered as follows.

- Let entryShortTerm be a variable ranging over all reference entries that are currently marked as "used for short-term reference". When some values of entryShortTerm are present having PicOrderCnt(entryShortTerm) less than PicOrderCnt(CurrPic), these values of entryShortTerm are placed at the beginning of refPicList0 in descending order of PicOrderCnt(entryShortTerm). All of the remaining values of entryShortTerm (when present) are then appended to refPicList0 in ascending order of PicOrderCnt(entryShortTerm).
- The long-term reference entries are ordered starting with the long-term reference entry that has the lowest LongTermPicNum value and proceeding through in ascending order to the long-term reference entry that has the highest LongTermPicNum value.

The reference picture list RefPicList1 is ordered so that short-term reference entries have lower indices than long-term reference entries. It is ordered as follows.

- Let entryShortTerm be a variable ranging over all reference entries that are currently marked as "used for short-term reference". When some values of entryShortTerm are present having PicOrderCnt(entryShortTerm) greater than PicOrderCnt(CurrPic), these values of entryShortTerm are placed at the beginning of refPicList1 in ascending order of PicOrderCnt(entryShortTerm). All of the remaining values of entryShortTerm (when present) are then appended to refPicList1 in descending order of PicOrderCnt(entryShortTerm).
- Long-term reference entries are ordered starting with the long-term reference frame or complementary reference field pair that has the lowest LongTermPicNum value and proceeding through in ascending order to the long-term reference entry that has the highest LongTermPicNum value.
- When the reference picture list RefPicList1 has more than one entry and RefPicList1 is identical to the reference picture list RefPicList0, the first two entries RefPicList1[0] and RefPicList1[1] are switched.

NOTE 2 – A non-paired reference field is not used for inter prediction of frames (independent of the value of MbaffFrameFlag).

8.2.4.2.4 Initialisation process for reference picture lists for B slices in fields

This initialisation process is invoked when decoding a B slice in a coded field.

When decoding a field, each field of a stored reference frame is identified as a separate reference picture with a unique index. The order of short-term reference pictures in the reference picture lists RefPicList0 and RefPicList1 depend on output order, as given by PicOrderCnt(). When pic_order_cnt_type is equal to 0, reference pictures that are marked as "non-existing" as specified in subclause 8.2.5.2 are not included in either RefPicList0 or RefPicList1.

NOTE 1 – When gaps_in_frame_num_value_allowed_flag is equal to 1, encoders should use reference picture list reordering to ensure proper operation of the decoding process (particularly when pic_order_cnt_type is equal to 0, in which case PicOrderCnt() is not inferred for "non-existing" frames).

NOTE 2 – When decoding a field, there are effectively at least twice as many pictures available for referencing as there would be when decoding a frame at the same position in decoding order.

Three ordered lists of reference frames, refFrameList0ShortTerm, refFrameList1ShortTerm and refFrameListLongTerm, are derived as follows. For purposes of the formation of these lists of frames the term reference entry refers in the following to decoded reference frames, complementary reference field pairs, or non-paired reference

fields. When `pic_order_cnt_type` is equal to 0, the term reference entry does not refer to frames that are marked as "non-existing" as specified in subclause 8.2.5.2.

- Let `entryShortTerm` be a variable ranging over all reference entries that are currently marked as "used for short-term reference". When some values of `entryShortTerm` are present having `PicOrderCnt(entryShortTerm)` less than or equal to `PicOrderCnt(CurrPic)`, these values of `entryShortTerm` are placed at the beginning of `refFrameList0ShortTerm` in descending order of `PicOrderCnt(entryShortTerm)`. All of the remaining values of `entryShortTerm` (when present) are then appended to `refFrameList0ShortTerm` in ascending order of `PicOrderCnt(entryShortTerm)`.

NOTE 3 – When the current field follows in decoding order a coded field `fldPrev` with which together it forms a complementary reference field pair, `fldPrev` is included into the list `refFrameList0ShortTerm` using `PicOrderCnt(fldPrev)` and the ordering method described in the previous sentence is applied.

- Let `entryShortTerm` be a variable ranging over all reference entries that are currently marked as "used for short-term reference". When some values of `entryShortTerm` are present having `PicOrderCnt(entryShortTerm)` greater than `PicOrderCnt(CurrPic)`, these values of `entryShortTerm` are placed at the beginning of `refFrameList1ShortTerm` in ascending order of `PicOrderCnt(entryShortTerm)`. All of the remaining values of `entryShortTerm` (when present) are then appended to `refFrameList1ShortTerm` in descending order of `PicOrderCnt(entryShortTerm)`.

NOTE 4 – When the current field follows in decoding order a coded field `fldPrev` with which together it forms a complementary reference field pair, `fldPrev` is included into the list `refFrameList1ShortTerm` using `PicOrderCnt(fldPrev)` and the ordering method described in the previous sentence is applied.

- `refFrameListLongTerm` is ordered starting with the reference entry having the lowest `LongTermFrameIdx` value and proceeding through in ascending order to the reference entry having highest `LongTermFrameIdx` value.

NOTE 5 – When the complementary field of the current picture is marked "used for long-term reference" it is included into the list `refFrameListLongTerm`. A reference entry in which only one field is marked as "used for long-term reference" is included into the list `refFrameListLongTerm`.

The process specified in subclause 8.2.4.2.5 is invoked with `refFrameList0ShortTerm` and `refFrameListLongTerm` given as input and the output is assigned to `RefPicList0`.

The process specified in subclause 8.2.4.2.5 is invoked with `refFrameList1ShortTerm` and `refFrameListLongTerm` given as input and the output is assigned to `RefPicList1`.

When the reference picture list `RefPicList1` has more than one entry and `RefPicList1` is identical to the reference picture list `RefPicList0`, the first two entries `RefPicList1[0]` and `RefPicList1[1]` are switched.

8.2.4.2.5 Initialisation process for reference picture lists in fields

Inputs of this process are the reference frame lists `refFrameListXShortTerm` (with `X` may be 0 or 1) and `refFrameListLongTerm`.

The reference picture list `RefPicListX` is a list ordered such that short-term reference fields have lower indices than long-term reference fields. Given the reference frame lists `refFrameListXShortTerm` and `refFrameListLongTerm`, it is derived as follows.

- Short-term reference fields are ordered by selecting reference fields from the ordered list of frames `refFrameListXShortTerm` by alternating between fields of differing parity, starting with a field that has the same parity as the current field (when present). When one field of a reference frame was not decoded or is not marked as "used for short-term reference", the missing field is ignored and instead the next available stored reference field of the chosen parity from the ordered list of frames `refFrameListXShortTerm` is inserted into `RefPicListX`. When there are no more short-term reference fields of the alternate parity in the ordered list of frames `refFrameListXShortTerm`, the next not yet indexed fields of the available parity are inserted into `RefPicListX` in the order in which they occur in the ordered list of frames `refFrameListXShortTerm`.
- Long-term reference fields are ordered by selecting reference fields from the ordered list of frames `refFrameListLongTerm` by alternating between fields of differing parity, starting with a field that has the same parity as the current field (when present). When one field of a reference frame was not decoded or is not marked as "used for long-term reference", the missing field is ignored and instead the next available stored reference field of the chosen parity from the ordered list of frames `refFrameListLongTerm` is inserted into `RefPicListX`. When there are no more long-term reference fields of the alternate parity in the ordered list of frames `refFrameListLongTerm`, the next not yet indexed fields of the available parity are inserted into `RefPicListX` in the order in which they occur in the ordered list of frames `refFrameListLongTerm`.

8.2.4.3 Reordering process for reference picture lists

When `ref_pic_list_reordering_flag_l0` is equal to 1, the following applies.

- Let `refIdxL0` be an index into the reference picture list `RefPicList0`. It is initially set equal to 0.

- The corresponding syntax elements `reordering_of_pic_nums_idc` are processed in the order they occur in the bitstream. For each of these syntax elements, the following applies.
 - If `reordering_of_pic_nums_idc` is equal to 0 or equal to 1, the process specified in subclause 8.2.4.3.1 is invoked with `refIdxL0` as input, and the output is assigned to `refIdxL0`.
 - Otherwise, if `reordering_of_pic_nums_idc` is equal to 2, the process specified in subclause 8.2.4.3.2 is invoked with `refIdxL0` as input, and the output is assigned to `refIdxL0`.
 - Otherwise (`reordering_of_pic_nums_idc` is equal to 3), the reordering process for reference picture list `RefPicList0` is finished.

When `ref_pic_list_reordering_flag_l1` is equal to 1, the following applies.

- Let `refIdxL1` be an index into the reference picture list `RefPicList1`. It is initially set equal to 0.
- The corresponding syntax elements `reordering_of_pic_nums_idc` are processed in the order they occur in the bitstream. For each of these syntax elements, the following applies.
 - If `reordering_of_pic_nums_idc` is equal to 0 or equal to 1, the process specified in subclause 8.2.4.3.1 is invoked with `refIdxL1` as input, and the output is assigned to `refIdxL1`.
 - Otherwise, if `reordering_of_pic_nums_idc` is equal to 2, the process specified in subclause 8.2.4.3.2 is invoked with `refIdxL1` as input, and the output is assigned to `refIdxL1`.
 - Otherwise (`reordering_of_pic_nums_idc` is equal to 3), the reordering process for reference picture list `RefPicList1` is finished.

8.2.4.3.1 Reordering process of reference picture lists for short-term reference pictures

Input to this process is an index `refIdxLX` (with `X` being 0 or 1).

Output of this process is an incremented index `refIdxLX`.

The variable `picNumLXNoWrap` is derived as follows.

- If `reordering_of_pic_nums_idc` is equal to 0

$$\begin{aligned} &\text{if(picNumLXPred - (abs_diff_pic_num_minus1 + 1) < 0)} \\ &\quad \text{picNumLXNoWrap} = \text{picNumLXPred} - (\text{abs_diff_pic_num_minus1} + 1) + \text{MaxPicNum} \\ &\text{else} \\ &\quad \text{picNumLXNoWrap} = \text{picNumLXPred} - (\text{abs_diff_pic_num_minus1} + 1) \end{aligned} \tag{8-35}$$

- Otherwise (`reordering_of_pic_nums_idc` is equal to 1),

$$\begin{aligned} &\text{if(picNumLXPred + (abs_diff_pic_num_minus1 + 1) \geq \text{MaxPicNum})} \\ &\quad \text{picNumLXNoWrap} = \text{picNumLXPred} + (\text{abs_diff_pic_num_minus1} + 1) - \text{MaxPicNum} \\ &\text{else} \\ &\quad \text{picNumLXNoWrap} = \text{picNumLXPred} + (\text{abs_diff_pic_num_minus1} + 1) \end{aligned} \tag{8-36}$$

`picNumLXPred` is the prediction value for the variable `picNumLXNoWrap`. When the process specified in this subclause is invoked the first time for a slice (that is, for the first occurrence of `reordering_of_pic_nums_idc` equal to 0 or 1 in the `ref_pic_list_reordering()` syntax), `picNumL0Pred` and `picNumL1Pred` are initially set equal to `CurrPicNum`. After each assignment of `picNumLXNoWrap`, the value of `picNumLXNoWrap` is assigned to `picNumLXPred`.

The variable `picNumLX` is derived as follows

$$\begin{aligned} &\text{if(picNumLXNoWrap > CurrPicNum)} \\ &\quad \text{picNumLX} = \text{picNumLXNoWrap} - \text{MaxPicNum} \\ &\text{else} \\ &\quad \text{picNumLX} = \text{picNumLXNoWrap} \end{aligned} \tag{8-37}$$

`picNumLX` shall be equal to the `PicNum` of a reference picture that is marked as “used for short-term reference” and shall not be equal to the `PicNum` of a short-term reference picture that is marked as “non-existing”.

The following procedure is conducted to place the picture with short-term picture number `picNumLX` into the index position `refIdxLX`, shift the position of any other remaining pictures to later in the list, and increment the value of `refIdxLX`.

```

for( cIdx = num_ref_idx_lX_active_minus1 + 1; cIdx > refIdxLX; cIdx-- )
    RefPicListX[ cIdx ] = RefPicListX[ cIdx - 1 ]
RefPicListX[ refIdxLX++ ] = short-term reference picture with PicNum equal to picNumLX
nIdx = refIdxLX
for( cIdx = refIdxLX; cIdx <= num_ref_idx_lX_active_minus1 + 1; cIdx++ )
    if( PicNumF( RefPicListX[ cIdx ] ) != picNumLX )
        RefPicListX[ nIdx++ ] = RefPicListX[ cIdx ]

```

(8-38)

where the function PicNumF(RefPicListX[cIdx]) is derived as follows:

- If the picture RefPicListX[cIdx] is marked as "used for short-term reference", PicNumF(RefPicListX[cIdx]) is the PicNum of the picture RefPicListX[cIdx].
- Otherwise (the picture RefPicListX[cIdx] is not marked as "used for short-term reference"), PicNumF(RefPicListX[cIdx]) is equal to MaxPicNum.

NOTE 1 – A value of MaxPicNum can never be equal to picNumLX.

NOTE 2 – Within this pseudo-code procedure, the length of the list RefPicListX is temporarily made one element longer than the length needed for the final list. After the execution of this procedure, only elements 0 through num_ref_idx_lX_active_minus1 of the list need to be retained.

8.2.4.3.2 Reordering process of reference picture lists for long-term reference pictures

Input to this process is an index refIdxLX (with X being 0 or 1).

Output of this process is an incremented index refIdxLX.

The following procedure is conducted to place the picture with long-term picture number long_term_pic_num into the index position refIdxLX, shift the position of any other remaining pictures to later in the list, and increment the value of refIdxLX.

```

for( cIdx = num_ref_idx_lX_active_minus1 + 1; cIdx > refIdxLX; cIdx-- )
    RefPicListX[ cIdx ] = RefPicListX[ cIdx - 1 ]
RefPicListX[ refIdxLX++ ] = long-term reference picture with LongTermPicNum equal to long_term_pic_num
nIdx = refIdxLX
for( cIdx = refIdxLX; cIdx <= num_ref_idx_lX_active_minus1 + 1; cIdx++ )
    if( LongTermPicNumF( RefPicListX[ cIdx ] ) != long_term_pic_num )
        RefPicListX[ nIdx++ ] = RefPicListX[ cIdx ]

```

(8-39)

where the function LongTermPicNumF(RefPicListX[cIdx]) is derived as follows:

- If the picture RefPicListX[cIdx] is marked as "used for long-term reference", LongTermPicNumF(RefPicListX[cIdx]) is the LongTermPicNum of the picture RefPicListX[cIdx].
- Otherwise (the picture RefPicListX[cIdx] is not marked as "used for long-term reference"), LongTermPicNumF(RefPicListX[cIdx]) is equal to 2 * (MaxLongTermFrameIdx + 1).

NOTE 1 – A value of 2 * (MaxLongTermFrameIdx + 1) can never be equal to long_term_pic_num.

NOTE 2 – Within this pseudo-code procedure, the length of the list RefPicListX is temporarily made one element longer than the length needed for the final list. After the execution of this procedure, only elements 0 through num_ref_idx_lX_active_minus1 of the list need to be retained.

8.2.5 Decoded reference picture marking process

This process is invoked for decoded pictures when nal_ref_idc is not equal to 0.

NOTE – The decoding process for gaps in frame_num that is specified in subclause 8.2.5.2 may also be invoked when nal_ref_idc is equal to 0, as specified in clause 8.

A decoded picture with nal_ref_idc not equal to 0, referred to as a reference picture, is marked as "used for short-term reference" or "used for long-term reference". For a decoded reference frame, both of its fields are marked the same as the frame. For a complementary reference field pair, the pair is marked the same as both of its fields. A picture that is marked as "used for short-term reference" is identified by its FrameNum and, when it is a field, by its parity. A picture that is marked as "used for long-term reference" is identified by its LongTermFrameIdx and, when it is a field, by its parity.

Frames or complementary field pairs marked as "used for short-term reference" or as "used for long-term reference" can be used as a reference for inter prediction when decoding a frame until the frame, the complementary field pair, or one of its constituent fields is marked as "unused for reference". A field marked as "used for short-term reference" or as

"used for long-term reference" can be used as a reference for inter prediction when decoding a field until marked as "unused for reference".

A picture can be marked as "unused for reference" by the sliding window reference picture marking process, a first-in, first-out mechanism specified in subclause 8.2.5.3 or by the adaptive memory control reference picture marking process, a customised adaptive marking operation specified in subclause 8.2.5.4.

A short-term reference picture is identified for use in the decoding process by its variables `FrameNum` and `FrameNumWrap` and its picture number `PicNum`, and a long-term reference picture is identified for use in the decoding process by its long-term picture number `LongTermPicNum`. When the current picture is not an IDR picture, subclause 8.2.4.1 is invoked to specify the assignment of the variables `FrameNum`, `FrameNumWrap`, `PicNum` and `LongTermPicNum`.

8.2.5.1 Sequence of operations for decoded reference picture marking process

Decoded reference picture marking proceeds in the following ordered steps.

1. All slices of the current picture are decoded.
2. Depending on whether the current picture is an IDR picture, the following applies.
 - If the current picture is an IDR picture, the following applies.
 - All reference pictures are marked as "unused for reference"
 - Depending on `long_term_reference_flag`, the following applies.
 - If `long_term_reference_flag` is equal to 0, the IDR picture is marked as "used for short-term reference" and `MaxLongTermFrameIdx` is set equal to "no long-term frame indices".
 - Otherwise (`long_term_reference_flag` is equal to 1), the IDR picture is marked as "used for long-term reference", the `LongTermFrameIdx` for the IDR picture is set equal to 0, and `MaxLongTermFrameIdx` is set equal to 0.
 - Otherwise (the current picture is not an IDR picture), the following applies.
 - If `adaptive_ref_pic_marking_mode_flag` is equal to 0, the process specified in subclause 8.2.5.3 is invoked.
 - Otherwise (`adaptive_ref_pic_marking_mode_flag` is equal to 1), the process specified in subclause 8.2.5.4 is invoked.
3. When the current picture is not an IDR picture and it was not marked as "used for long-term reference" by `memory_management_control_operation` equal to 6, it is marked as "used for short-term reference".

After marking the current decoded reference picture, the total number of frames with at least one field marked as "used for reference", plus the number of complementary field pairs with at least one field marked as "used for reference", plus the number of non-paired fields marked as "used for reference" shall not be greater than $\text{Max}(\text{num_ref_frames}, 1)$.

8.2.5.2 Decoding process for gaps in `frame_num`

This process is invoked when `frame_num` is not equal to `PrevRefFrameNum` and is not equal to $(\text{PrevRefFrameNum} + 1) \% \text{MaxFrameNum}$.

NOTE 1 – Although this process is specified as a subclause within subclause 8.2.5 (which defines a process that is invoked only when `nal_ref_idc` is not equal to 0), this process may also be invoked when `nal_ref_idc` is equal to 0 (as specified in clause 8). The reasons for the location of this subclause within the structure of this Recommendation | International Standard are historical.

NOTE 2 – This process can only be invoked for a conforming bitstream when `gaps_in_frame_num_value_allowed_flag` is equal to 1. When `gaps_in_frame_num_value_allowed_flag` is equal to 0 and `frame_num` is not equal to `PrevRefFrameNum` and is not equal to $(\text{PrevRefFrameNum} + 1) \% \text{MaxFrameNum}$, the decoding process should infer an unintentional loss of pictures.

When this process is invoked, a set of values of `frame_num` pertaining to "non-existing" pictures is derived as all values taken on by `UnusedShortTermFrameNum` in Equation 7-21 except the value of `frame_num` for the current picture.

The decoding process generates and marks a frame for each of the values of `frame_num` pertaining to "non-existing" pictures, in the order in which the values of `UnusedShortTermFrameNum` are generated by Equation 7-21, using the "sliding window" picture marking process as specified in subclause 8.2.5.3. The generated frames are also marked as "non-existing" and "used for short-term reference". The sample values of the generated frames may be set to any value. The bitstream shall not contain data that results in a reference to these generated frames which are marked as "non-existing" in the inter prediction process, a reference to these frames in the reordering commands for reference picture lists for short-term reference pictures (subclause 8.2.4.3.1), or a reference to these frames in the assignment process of a `LongTermFrameIdx` to a short-term reference picture (subclause 8.2.5.4.3).

When `pic_order_cnt_type` is not equal to 0, `TopFieldOrderCnt` and `BottomFieldOrderCnt` are derived for each of the "non-existing" frames by invoking the decoding process for picture order count in subclause 8.2.1. When invoking the process in subclause 8.2.1 for a particular "non-existing" frame, the current picture is considered to be a picture considered having `frame_num` inferred to be equal to `UnusedShortTermFrameNum`, `nal_ref_idc` inferred to be not equal to 0, `nal_unit_type` inferred to be not equal to 5, `field_pic_flag` inferred to be equal to 0, `adaptive_ref_pic_marking_mode_flag` inferred to be equal to 0, `delta_pic_order_cnt[0]` (if needed) inferred to be equal to 0, and `delta_pic_order_cnt[1]` (if needed) inferred to be equal to 0.

NOTE 3 – The decoding process should infer an unintentional picture loss when any of these values of `frame_num` pertaining to "non-existing" pictures is referred to in the inter prediction process, is referred to in the reordering commands for reference picture lists for short-term reference pictures (subclause 8.2.4.3.1), or is referred to in the assignment process of a `LongTermFrameIdx` to a short-term reference picture (subclause 8.2.5.4.3). The decoding process should not infer an unintentional picture loss when a memory management control operation not equal to 3 is applied to a frame marked as "non-existing".

8.2.5.3 Sliding window decoded reference picture marking process

This process is invoked when `adaptive_ref_pic_marking_mode_flag` is equal to 0.

Depending on the properties of the current picture as specified below, the following applies.

- If the current picture is a coded field that is the second field in decoding order of a complementary reference field pair, and the first field has been marked as "used for short-term reference", the current picture is also marked as "used for short-term reference".
- Otherwise, the following applies.
 - Let `numShortTerm` be the total number of reference frames, complementary reference field pairs and non-paired reference fields for which at least one field is marked as "used for short-term reference". Let `numLongTerm` be the total number of reference frames, complementary reference field pairs and non-paired reference fields for which at least one field is marked as "used for long-term reference".
 - When `numShortTerm + numLongTerm` is equal to `Max(num_ref_frames, 1)`, the condition that `numShortTerm` is greater than 0 shall be fulfilled, and the short-term reference frame, complementary reference field pair or non-paired reference field that has the smallest value of `FrameNumWrap` is marked as "unused for reference". When it is a frame or a complementary field pair, both of its fields are also marked as "unused for reference".

8.2.5.4 Adaptive memory control decoded reference picture marking process

This process is invoked when `adaptive_ref_pic_marking_mode_flag` is equal to 1.

The `memory_management_control_operation` commands with values of 1 to 6 are processed in the order they occur in the bitstream after the current picture has been decoded. For each of these `memory_management_control_operation` commands, one of the processes specified in subclauses 8.2.5.4.1 to 8.2.5.4.5 is invoked depending on the value of `memory_management_control_operation`. The `memory_management_control_operation` command with value of 0 specifies the end of `memory_management_control_operation` commands.

Memory management control operations are applied to pictures as follows.

- If `field_pic_flag` is equal to 0, `memory_management_control_operation` commands are applied to the frames or complementary reference field pairs specified.
- Otherwise (`field_pic_flag` is equal to 1), `memory_management_control_operation` commands are applied to the individual reference fields specified.

8.2.5.4.1 Marking process of a short-term reference picture as "unused for reference"

This process is invoked when `memory_management_control_operation` is equal to 1.

Let `picNumX` be specified by

$$\text{picNumX} = \text{CurrPicNum} - (\text{difference_of_pic_nums_minus1} + 1). \quad (8-40)$$

Depending on `field_pic_flag` the value of `picNumX` is used to mark a short-term reference picture as "unused for reference" as follows.

- If `field_pic_flag` is equal to 0, the short-term reference frame or short-term complementary reference field pair specified by `picNumX` and both of its fields are marked as "unused for reference".
- Otherwise (`field_pic_flag` is equal to 1), the short-term reference field specified by `picNumX` is marked as "unused for reference". When that reference field is part of a reference frame or a complementary reference field pair, the

frame or complementary field pair is also marked as "unused for reference", but the marking of the other field is not changed.

8.2.5.4.2 Marking process of a long-term reference picture as “unused for reference”

This process is invoked when memory_management_control_operation is equal to 2.

Depending on field_pic_flag the value of LongTermPicNum is used to mark a long-term reference picture as “unused for reference” as follows.

- If field_pic_flag is equal to 0, the long-term reference frame or long-term complementary reference field pair having LongTermPicNum equal to long_term_pic_num and both of its fields are marked as “unused for reference”.
- Otherwise (field_pic_flag is equal to 1), the long-term reference field specified by LongTermPicNum equal to long_term_pic_num is marked as “unused for reference”. When that reference field is part of a reference frame or a complementary reference field pair, the frame or complementary field pair is also marked as "unused for reference", but the marking of the other field is not changed.

8.2.5.4.3 Assignment process of a LongTermFrameIdx to a short-term reference picture

This process is invoked when memory_management_control_operation is equal to 3.

Given the syntax element difference_of_pic_nums_minus1, the variable picNumX is obtained as specified in subclause 8.2.5.4.1. picNumX shall refer to a frame or complementary reference field pair or non-paired reference field marked as "used for short-term reference" and not marked as "non-existing".

When LongTermFrameIdx equal to long_term_frame_idx is already assigned to a long-term reference frame or a long-term complementary reference field pair, that frame or complementary field pair and both of its fields are marked as "unused for reference". When LongTermFrameIdx is already assigned to a non-paired reference field, and the field is not the complementary field of the picture specified by picNumX, that field is marked as “unused for reference”.

Depending on field_pic_flag the value of LongTermFrameIdx is used to mark a picture from "used for short-term reference" to "used for long-term reference" as follows.

- If field_pic_flag is equal to 0, the marking of the short-term reference frame or short-term complementary reference field pair specified by picNumX and both of its fields are changed from "used for short-term reference" to "used for long-term reference" and assigned LongTermFrameIdx equal to long_term_frame_idx.
- Otherwise (field_pic_flag is equal to 1), the marking of the short-term reference field specified by picNumX is changed from "used for short-term reference" to "used for long-term reference" and assigned LongTermFrameIdx equal to long_term_frame_idx. When the field is part of a reference frame or a complementary reference field pair, and the other field of the same reference frame or complementary reference field pair is also marked as "used for long-term reference", the reference frame or complementary reference field pair is also marked as "used for long-term reference" and assigned LongTermFrameIdx equal to long_term_frame_idx.

8.2.5.4.4 Decoding process for MaxLongTermFrameIdx

This process is invoked when memory_management_control_operation is equal to 4.

All pictures for which LongTermFrameIdx is greater than max_long_term_frame_idx_plus1 – 1 and that are marked as "used for long-term reference" are marked as “unused for reference”.

The variable MaxLongTermFrameIdx is derived as follows.

- If max_long_term_frame_idx_plus1 is equal to 0, MaxLongTermFrameIdx is set equal to “no long-term frame indices”.
- Otherwise (max_long_term_frame_idx_plus1 is greater than 0), MaxLongTermFrameIdx is set equal to max_long_term_frame_idx_plus1 – 1.

NOTE – The memory_management_control_operation command equal to 4 can be used to mark long-term reference pictures as “unused for reference”. The frequency of transmitting max_long_term_frame_idx_plus1 is not specified by this Recommendation | International Standard. However, the encoder should send a memory_management_control_operation command equal to 4 upon receiving an error message, such as an intra refresh request message.

8.2.5.4.4.1 Marking process of all reference pictures as “unused for reference” and setting MaxLongTermFrameIdx to “no long-term frame indices”

This process is invoked when memory_management_control_operation is equal to 5.

All reference pictures are marked as “unused for reference” and the variable MaxLongTermFrameIdx is set equal to “no long-term frame indices”.

8.2.5.4.5 Process for assigning a long-term frame index to the current picture

This process is invoked when memory_management_control_operation is equal to 6.

When a variable LongTermFrameIdx equal to long_term_frame_idx is already assigned to a long-term reference frame or a long-term complementary reference field pair, that frame or complementary field pair and both of its fields are marked as "unused for reference". When LongTermFrameIdx is already assigned to a non-paired reference field, and the field is not the complementary field of the current picture, that field is marked as “unused for reference”.

The current picture is marked as "used for long-term reference" and assigned LongTermFrameIdx equal to long_term_frame_idx.

When field_pic_flag is equal to 0, both its fields are also marked as "used for long-term reference" and assigned LongTermFrameIdx equal to long_term_frame_idx.

When field_pic_flag is equal to 1 and the current picture is the second field (in decoding order) of a complementary reference field pair, and the first field of the complementary reference field pair is also currently marked as "used for long-term reference", the complementary reference field pair is also marked as "used for long-term reference" and assigned LongTermFrameIdx equal to long_term_frame_idx.

After marking the current decoded reference picture, the total number of frames with at least one field marked as “used for reference”, plus the number of complementary field pairs with at least one field marked as “used for reference”, plus the number of non-paired fields marked as “used for reference” shall not be greater than Max(num_ref_frames, 1).

NOTE – Under some circumstances, the above statement may impose a constraint on the order in which a memory_management_control_operation syntax element equal to 6 can appear in the decoded reference picture marking syntax relative to a memory_management_control_operation syntax element equal to 1, 2, or 4.

8.3 Intra prediction process

This process is invoked for I and SI macroblock types.

Inputs to this process are constructed samples prior to the deblocking filter process and, for Intra_NxN prediction modes (where NxN is equal to 4x4 or 8x8), the values of IntraNxNPredMode from neighbouring macroblocks.

Outputs of this process are specified as follows.

- If the macroblock prediction mode is Intra_4x4 or Intra_8x8, the outputs are constructed luma samples prior to the deblocking filter process and (when chroma_format_idc is not equal to 0) chroma prediction samples of the macroblock pred_C, where C is equal to Cb and Cr.
- Otherwise, if mb_type is not equal to I_PCM, the outputs are luma prediction samples of the macroblock pred_L and (when chroma_format_idc is not equal to 0) chroma prediction samples of the macroblock pred_C, where C is equal to Cb and Cr.
- Otherwise (mb_type is equal to I_PCM), the outputs are constructed luma and (when chroma_format_idc is not equal to 0) chroma samples prior to the deblocking filter process.

The variable MvCnt is set equal to 0.

Depending on the value of mb_type the following applies.

- If mb_type is equal to I_PCM, the process specified in subclause 8.3.5 is invoked.
- Otherwise (mb_type is not equal to I_PCM), the following applies.
 - The decoding processes for Intra prediction modes are described for the luma component as follows.
 - If the macroblock prediction mode is equal to Intra_4x4, the specification in subclause 8.3.1 applies.
 - Otherwise, if the macroblock prediction mode is equal to Intra_8x8, the specification in subclause 8.3.2 applies.
 - Otherwise (the macroblock prediction mode is equal to Intra_16x16), the specification in subclause 8.3.3 applies.
 - The decoding processes for Intra prediction modes for the chroma components are described in subclause 8.3.4. This process is only invoked when chroma_format_idc is not equal to 0 (monochrome).

Samples used in the Intra prediction process are the sample values prior to alteration by any deblocking filter operation.

8.3.1 Intra_4x4 prediction process for luma samples

This process is invoked when the macroblock prediction mode is equal to Intra_4x4.

Inputs to this process are the values of Intra4x4PredMode (if available) or Intra8x8PredMode (if available) from neighbouring macroblocks or macroblock pairs.

The luma component of a macroblock consists of 16 blocks of 4x4 luma samples. These blocks are inverse scanned using the 4x4 luma block inverse scanning process as specified in subclause 6.4.3.

For all 4x4 luma blocks of the luma component of a macroblock with luma4x4BlkIdx = 0..15, the derivation process for the Intra4x4PredMode as specified in subclause 8.3.1.1 is invoked with luma4x4BlkIdx as well as Intra4x4PredMode and Intra8x8PredMode that are previously (in decoding order) derived for adjacent macroblocks as the input and the variable Intra4x4PredMode[luma4x4BlkIdx] as the output.

For each luma block of 4x4 samples indexed using luma4x4BlkIdx = 0..15,

1. The Intra_4x4 sample prediction process in subclause 8.3.1.2 is invoked with luma4x4BlkIdx and constructed samples prior (in decoding order) to the deblocking filter process from adjacent luma blocks as the input and the output are the Intra_4x4 luma prediction samples $\text{pred}_{4x4L}[x, y]$ with $x, y = 0..3$.
2. The position of the upper-left sample of a 4x4 luma block with index luma4x4BlkIdx inside the current macroblock is derived by invoking the inverse 4x4 luma block scanning process in subclause 6.4.3 with luma4x4BlkIdx as the input and the output being assigned to (xO, yO) and $x, y = 0..3$.

$$\text{pred}_L[xO + x, yO + y] = \text{pred}_{4x4L}[x, y] \quad (8-41)$$

3. The transform coefficient decoding process and picture construction process prior to deblocking filter process in subclause 8.5 is invoked with pred_L and luma4x4BlkIdx as the input and the constructed samples for the current 4x4 luma block S'_L as the output.

8.3.1.1 Derivation process for the Intra4x4PredMode

Inputs to this process are the index of the 4x4 luma block luma4x4BlkIdx and variable arrays Intra4x4PredMode (if available) and Intra8x8PredMode (if available) that are previously (in decoding order) derived for adjacent macroblocks.

Output of this process is the variable Intra4x4PredMode[luma4x4BlkIdx].

Table 8-2 specifies the values for Intra4x4PredMode[luma4x4BlkIdx] and the associated names.

Table 8-2 – Specification of Intra4x4PredMode[luma4x4BlkIdx] and associated names

Intra4x4PredMode[luma4x4BlkIdx]	Name of Intra4x4PredMode[luma4x4BlkIdx]
0	Intra_4x4_Vertical (prediction mode)
1	Intra_4x4_Horizontal (prediction mode)
2	Intra_4x4_DC (prediction mode)
3	Intra_4x4_Diagonal_Down_Left (prediction mode)
4	Intra_4x4_Diagonal_Down_Right (prediction mode)
5	Intra_4x4_Vertical_Right (prediction mode)
6	Intra_4x4_Horizontal_Down (prediction mode)
7	Intra_4x4_Vertical_Left (prediction mode)
8	Intra_4x4_Horizontal_Up (prediction mode)

Intra4x4PredMode[luma4x4BlkIdx] labelled 0, 1, 3, 4, 5, 6, 7, and 8 represent directions of predictions as illustrated in Figure 8-1.

Figure 8-1 – Intra_4x4 prediction mode directions (informative)

$\text{Intra4x4PredMode}[\text{luma4x4BlkIdx}]$ is derived as follows.

- The process specified in subclause 6.4.8.3 is invoked with luma4x4BlkIdx given as input and the output is assigned to mbAddrA , luma4x4BlkIdxA , mbAddrB , and luma4x4BlkIdxB .
- The variable $\text{dcPredModePredictedFlag}$ is derived as follows.
 - If any of the following conditions are true, $\text{dcPredModePredictedFlag}$ is set equal to 1
 - the macroblock with address mbAddrA is not available
 - the macroblock with address mbAddrB is not available
 - the macroblock with address mbAddrA is available and coded in Inter prediction mode and $\text{constrained_intra_pred_flag}$ is equal to 1
 - the macroblock with address mbAddrB is available and coded in Inter prediction mode and $\text{constrained_intra_pred_flag}$ is equal to 1
 - Otherwise, $\text{dcPredModePredictedFlag}$ is set equal to 0.
- For N being either replaced by A or B, the variables intraMxMPredModeN are derived as follows.
 - If $\text{dcPredModePredictedFlag}$ is equal to 1 or the macroblock with address mbAddrN is not coded in Intra_4x4 or Intra_8x8 macroblock prediction mode, intraMxMPredModeN is set equal to 2 (Intra_4x4_DC prediction mode).
 - Otherwise ($\text{dcPredModePredictedFlag}$ is equal to 0 and (the macroblock with address mbAddrN is coded in Intra_4x4 macroblock prediction mode or the macroblock with address mbAddrN is coded in Intra_8x8 macroblock prediction mode)), the following applies.
 - If the macroblock with address mbAddrN is coded in Intra_4x4 macroblock mode, intraMxMPredModeN is set equal to $\text{Intra4x4PredMode}[\text{luma4x4BlkIdxN}]$, where Intra4x4PredMode is the variable array assigned to the macroblock mbAddrN .
 - Otherwise (the macroblock with address mbAddrN is coded in Intra_8x8 macroblock mode), intraMxMPredModeN is set equal to $\text{Intra8x8PredMode}[\text{luma4x4BlkIdxN} \gg 2]$, where Intra8x8PredMode is the variable array assigned to the macroblock mbAddrN .
- $\text{Intra4x4PredMode}[\text{luma4x4BlkIdx}]$ is derived by applying the following procedure.

```

predIntra4x4PredMode = Min( intraMxMPredModeA, intraMxMPredModeB )
if( prev_intra4x4_pred_mode_flag[ luma4x4BlkIdx ] )
    Intra4x4PredMode[ luma4x4BlkIdx ] = predIntra4x4PredMode
else
    if( rem_intra4x4_pred_mode[ luma4x4BlkIdx ] < predIntra4x4PredMode )
        Intra4x4PredMode[ luma4x4BlkIdx ] = rem_intra4x4_pred_mode[ luma4x4BlkIdx ]
    else
        Intra4x4PredMode[ luma4x4BlkIdx ] = rem_intra4x4_pred_mode[ luma4x4BlkIdx ] + 1

```

(8-42)

8.3.1.2 Intra_4x4 sample prediction

This process is invoked for each 4x4 luma block of a macroblock with prediction mode equal to Intra_4x4 followed by the transform decoding process and picture construction process prior to deblocking for each 4x4 luma block.

Input to this process is the index of a 4x4 luma block luma4x4BlkIdx.

Output of this process are the prediction samples $\text{pred4x4}_L[x, y]$, with $x, y = 0..3$ for the 4x4 luma block with index luma4x4BlkIdx.

The position of the upper-left sample of a 4x4 luma block with index luma4x4BlkIdx inside the current macroblock is derived by invoking the inverse 4x4 luma block scanning process in subclause 6.4.3 with luma4x4BlkIdx as the input and the output being assigned to (xO, yO).

The 13 neighbouring samples $p[x, y]$ that are constructed luma samples prior to the deblocking filter process, with $x = -1, y = -1..3$ and $x = 0..7, y = -1$, are derived as follows.

- The luma location (xN, yN) is specified by

$$xN = xO + x \quad (8-43)$$

$$yN = yO + y \quad (8-44)$$

- The derivation process for neighbouring locations in subclause 6.4.9 is invoked for luma locations with (xN, yN) as input and mbAddrN and (xW, yW) as output.
- Each sample $p[x, y]$ with $x = -1, y = -1..3$ and $x = 0..7, y = -1$ is derived as follows.
 - If any of the following conditions is true, the sample $p[x, y]$ is marked as “not available for Intra_4x4 prediction”
 - mbAddrN is not available,
 - the macroblock mbAddrN is coded in Inter prediction mode and constrained_intra_pred_flag is equal to 1.
 - the macroblock mbAddrN has mb_type equal to SI and constrained_intra_pred_flag is equal to 1 and the current macroblock does not have mb_type equal to SI.
 - x is greater than 3 and luma4x4BlkIdx is equal to 3 or 11
 - Otherwise, the sample $p[x, y]$ is marked as “available for Intra_4x4 prediction” and the luma sample at luma location (xW, yW) inside the macroblock mbAddrN is assigned to $p[x, y]$.

When samples $p[x, -1]$, with $x = 4..7$ are marked as “not available for Intra_4x4 prediction,” and the sample $p[3, -1]$ is marked as “available for Intra_4x4 prediction,” the sample value of $p[3, -1]$ is substituted for sample values $p[x, -1]$, with $x = 4..7$ and samples $p[x, -1]$, with $x = 4..7$ are marked as “available for Intra_4x4 prediction”.

NOTE – Each block is assumed to be constructed into a picture array prior to decoding of the next block.

Depending on Intra4x4PredMode[luma4x4BlkIdx], one of the Intra_4x4 prediction modes specified in subclauses 8.3.1.2.1 to 8.3.1.2.9 is invoked.

8.3.1.2.1 Specification of Intra_4x4_Veritical prediction mode

This Intra_4x4 prediction mode is invoked when Intra4x4PredMode[luma4x4BlkIdx] is equal to 0.

This mode shall be used only when the samples $p[x, -1]$ with $x = 0..3$ are marked as “available for Intra_4x4 prediction”.

The values of the prediction samples $\text{pred4x4}_L[x, y]$, with $x, y = 0..3$ are derived by

$$\text{pred4x4}_L[x, y] = p[x, -1], \text{ with } x, y = 0..3 \quad (8-45)$$

8.3.1.2.2 Specification of Intra_4x4_Horizontal prediction mode

This Intra_4x4 prediction mode is invoked when Intra4x4PredMode[luma4x4BlkIdx] is equal to 1.

This mode shall be used only when the samples $p[-1, y]$, with $y = 0..3$ are marked as “available for Intra_4x4 prediction”.

The values of the prediction samples $\text{pred4x4}_L[x, y]$, with $x, y = 0..3$ are derived by

$$\text{pred4x4}_L[x, y] = p[-1, y], \text{ with } x, y = 0..3 \quad (8-46)$$

8.3.1.2.3 Specification of Intra_4x4_DC prediction mode

This Intra_4x4 prediction mode is invoked when $\text{Intra4x4PredMode}[\text{luma4x4BlkIdx}]$ is equal to 2.

The values of the prediction samples $\text{pred4x4}_L[x, y]$, with $x, y = 0..3$ are derived as follows.

- If all samples $p[x, -1]$, with $x = 0..3$ and $p[-1, y]$, with $y = 0..3$ are marked as “available for Intra_4x4 prediction”, the values of the prediction samples $\text{pred4x4}_L[x, y]$, with $x, y = 0..3$ are derived by

$$\text{pred4x4}_L[x, y] = (p[0, -1] + p[1, -1] + p[2, -1] + p[3, -1] + p[-1, 0] + p[-1, 1] + p[-1, 2] + p[-1, 3] + 4) \gg 3 \quad (8-47)$$

- Otherwise, if any samples $p[x, -1]$, with $x = 0..3$ are marked as “not available for Intra_4x4 prediction” and all samples $p[-1, y]$, with $y = 0..3$ are marked as “available for Intra_4x4 prediction”, the values of the prediction samples $\text{pred4x4}_L[x, y]$, with $x, y = 0..3$ are derived by

$$\text{pred4x4}_L[x, y] = (p[-1, 0] + p[-1, 1] + p[-1, 2] + p[-1, 3] + 2) \gg 2 \quad (8-48)$$

- Otherwise, if any samples $p[-1, y]$, with $y = 0..3$ are marked as “not available for Intra_4x4 prediction” and all samples $p[x, -1]$, with $x = 0..3$ are marked as “available for Intra_4x4 prediction”, the values of the prediction samples $\text{pred4x4}_L[x, y]$, with $x, y = 0..3$ are derived by

$$\text{pred4x4}_L[x, y] = (p[0, -1] + p[1, -1] + p[2, -1] + p[3, -1] + 2) \gg 2 \quad (8-49)$$

- Otherwise (some samples $p[x, -1]$, with $x = 0..3$ and some samples $p[-1, y]$, with $y = 0..3$ are marked as “not available for Intra_4x4 prediction”), the values of the prediction samples $\text{pred4x4}_L[x, y]$, with $x, y = 0..3$ are derived by

$$\text{pred4x4}_L[x, y] = (1 \ll (\text{BitDepth}_Y - 1)) \quad (8-50)$$

NOTE – A 4x4 luma block can always be predicted using this mode.

8.3.1.2.4 Specification of Intra_4x4_Diagonal_Down_Left prediction mode

This Intra_4x4 prediction mode is invoked when $\text{Intra4x4PredMode}[\text{luma4x4BlkIdx}]$ is equal to 3.

This mode shall be used only when the samples $p[x, -1]$ with $x = 0..7$ are marked as “available for Intra_4x4 prediction”.

The values of the prediction samples $\text{pred4x4}_L[x, y]$, with $x, y = 0..3$ are derived as follows.

- If x is equal to 3 and y is equal to 3,

$$\text{pred4x4}_L[x, y] = (p[6, -1] + 3 * p[7, -1] + 2) \gg 2 \quad (8-51)$$

- Otherwise (x is not equal to 3 or y is not equal to 3),

$$\text{pred4x4}_L[x, y] = (p[x + y, -1] + 2 * p[x + y + 1, -1] + p[x + y + 2, -1] + 2) \gg 2 \quad (8-52)$$

8.3.1.2.5 Specification of Intra_4x4_Diagonal_Down_Right prediction mode

This Intra_4x4 prediction mode is invoked when $\text{Intra4x4PredMode}[\text{luma4x4BlkIdx}]$ is equal to 4.

This mode shall be used only when the samples $p[x, -1]$ with $x = 0..3$ and $p[-1, y]$ with $y = -1..3$ are marked as “available for Intra_4x4 prediction”.

The values of the prediction samples $\text{pred4x4}_L[x, y]$, with $x, y = 0..3$ are derived as follows.

- If x is greater than y ,

$$\text{pred4x4}_L[x, y] = (p[x - y - 2, -1] + 2 * p[x - y - 1, -1] + p[x - y, -1] + 2) >> 2 \quad (8-53)$$

- Otherwise if x is less than y,

$$\text{pred4x4}_L[x, y] = (p[-1, y - x - 2] + 2 * p[-1, y - x - 1] + p[-1, y - x] + 2) >> 2 \quad (8-54)$$

- Otherwise (x is equal to y),

$$\text{pred4x4}_L[x, y] = (p[0, -1] + 2 * p[-1, -1] + p[-1, 0] + 2) >> 2 \quad (8-55)$$

8.3.1.2.6 Specification of Intra_4x4_Vertical_Right prediction mode

This Intra_4x4 prediction mode is invoked when Intra4x4PredMode[luma4x4BlkIdx] is equal to 5.

This mode shall be used only when the samples $p[x, -1]$ with $x = 0..3$ and $p[-1, y]$ with $y = -1..3$ are marked as “available for Intra_4x4 prediction”.

Let the variable zVR be set equal to $2 * x - y$.

The values of the prediction samples $\text{pred4x4}_L[x, y]$, with $x, y = 0..3$ are derived as follows.

- If zVR is equal to 0, 2, 4, or 6,

$$\text{pred4x4}_L[x, y] = (p[x - (y >> 1) - 1, -1] + p[x - (y >> 1), -1] + 1) >> 1 \quad (8-56)$$

- Otherwise, if zVR is equal to 1, 3, or 5,

$$\text{pred4x4}_L[x, y] = (p[x - (y >> 1) - 2, -1] + 2 * p[x - (y >> 1) - 1, -1] + p[x - (y >> 1), -1] + 2) >> 2 \quad (8-57)$$

- Otherwise, if zVR is equal to -1,

$$\text{pred4x4}_L[x, y] = (p[-1, 0] + 2 * p[-1, -1] + p[0, -1] + 2) >> 2 \quad (8-58)$$

- Otherwise (zVR is equal to -2 or -3),

$$\text{pred4x4}_L[x, y] = (p[-1, y - 1] + 2 * p[-1, y - 2] + p[-1, y - 3] + 2) >> 2 \quad (8-59)$$

8.3.1.2.7 Specification of Intra_4x4_Horizontal_Down prediction mode

This Intra_4x4 prediction mode is invoked when Intra4x4PredMode[luma4x4BlkIdx] is equal to 6.

This mode shall be used only when the samples $p[x, -1]$ with $x = 0..3$ and $p[-1, y]$ with $y = -1..3$ are marked as “available for Intra_4x4 prediction”.

Let the variable zHD be set equal to $2 * y - x$.

The values of the prediction samples $\text{pred4x4}_L[x, y]$, with $x, y = 0..3$ are derived as follows.

- If zHD is equal to 0, 2, 4, or 6,

$$\text{pred4x4}_L[x, y] = (p[-1, y - (x >> 1) - 1] + p[-1, y - (x >> 1)] + 1) >> 1 \quad (8-60)$$

- Otherwise, if zHD is equal to 1, 3, or 5,

$$\text{pred4x4}_L[x, y] = (p[-1, y - (x >> 1) - 2] + 2 * p[-1, y - (x >> 1) - 1] + p[-1, y - (x >> 1)] + 2) >> 2 \quad (8-61)$$

- Otherwise, if zHD is equal to -1,

$$\text{pred4x4}_L[x, y] = (p[-1, 0] + 2 * p[-1, -1] + p[0, -1] + 2) >> 2 \quad (8-62)$$

- Otherwise (zHD is equal to -2 or -3),

$$\text{pred4x4}_L[x, y] = (p[x - 1, -1] + 2 * p[x - 2, -1] + p[x - 3, -1] + 2) >> 2 \quad (8-63)$$

8.3.1.2.8 Specification of Intra_4x4_Vertical_Left prediction mode

This Intra_4x4 prediction mode is invoked when Intra4x4PredMode[luma4x4BlkIdx] is equal to 7.

This mode shall be used only when the samples $p[x, -1]$ with $x = 0..7$ are marked as “available for Intra_4x4 prediction”.

The values of the prediction samples $\text{pred4x4}_L[x, y]$, with $x, y = 0..3$ are derived as follows.

- If y is equal to 0 or 2,

$$\text{pred4x4}_L[x, y] = (p[x + (y >> 1), -1] + p[x + (y >> 1) + 1, -1] + 1) >> 1 \quad (8-64)$$

- Otherwise (y is equal to 1 or 3),

$$\text{pred4x4}_L[x, y] = (p[x + (y >> 1), -1] + 2 * p[x + (y >> 1) + 1, -1] + p[x + (y >> 1) + 2, -1] + 2) >> 2 \quad (8-65)$$

8.3.1.2.9 Specification of Intra_4x4_Horizontal_Up prediction mode

This Intra_4x4 prediction mode is invoked when Intra4x4PredMode[luma4x4BlkIdx] is equal to 8.

This mode shall be used only when the samples $p[-1, y]$ with $y = 0..3$ are marked as “available for Intra_4x4 prediction”.

Let the variable zHU be set equal to $x + 2 * y$.

The values of the prediction samples $\text{pred4x4}_L[x, y]$, with $x, y = 0..3$ are derived as follows:

- If zHU is equal to 0, 2, or 4

$$\text{pred4x4}_L[x, y] = (p[-1, y + (x >> 1)] + p[-1, y + (x >> 1) + 1] + 1) >> 1 \quad (8-66)$$

- Otherwise, if zHU is equal to 1 or 3

$$\text{pred4x4}_L[x, y] = (p[-1, y + (x >> 1)] + 2 * p[-1, y + (x >> 1) + 1] + p[-1, y + (x >> 1) + 2] + 2) >> 2 \quad (8-67)$$

- Otherwise, if zHU is equal to 5,

$$\text{pred4x4}_L[x, y] = (p[-1, 2] + 3 * p[-1, 3] + 2) >> 2 \quad (8-68)$$

- Otherwise (zHU is greater than 5),

$$\text{pred4x4}_L[x, y] = p[-1, 3] \quad (8-69)$$

8.3.2 Intra_8x8 prediction process for luma samples

This process is invoked when the macroblock prediction mode is equal to Intra_8x8.

Inputs to this process are the values of Intra4x4PredMode (if available) or Intra8x8PredMode (if available) from the neighbouring macroblocks or macroblock pairs.

Outputs of this process are 8x8 luma sample arrays as part of the 16x16 luma array of prediction samples of the macroblock pred_L .

The luma component of a macroblock consists of 4 blocks of 8x8 luma samples. These blocks are inverse scanned using the inverse 8x8 luma block scanning process as specified in subclause 6.4.4.

For all 8x8 luma blocks of the luma component of a macroblock with $\text{luma8x8BlkIdx} = 0..3$, the derivation process for Intra8x8PredMode as specified in subclause 8.3.2.1 is invoked with luma8x8BlkIdx as well as Intra4x4PredMode and

Intra8x8PredMode that are previously (in decoding order) derived for adjacent macroblocks as the input and the variable Intra8x8PredMode[luma8x8BlkIdx] as the output.

For each luma block of 8x8 samples indexed using luma8x8BlkIdx = 0..3, the following applies.

- The Intra_8x8 sample prediction process in subclause 8.3.2.2 is invoked with luma8x8BlkIdx and constructed samples prior (in decoding order) to the deblocking filter process from adjacent luma blocks as the input and the output are the Intra_8x8 luma prediction samples pred8x8L[x, y] with x, y = 0..7.
- The position of the upper-left sample of an 8x8 luma block with index luma8x8BlkIdx inside the current macroblock is derived by invoking the inverse 8x8 luma block scanning process in subclause 6.4.4 with luma8x8BlkIdx as the input and the output being assigned to (xO, yO) and x, y = 0..7.

$$\text{pred}_L[xO + x, yO + y] = \text{pred8x8}_L[x, y] \quad (8-70)$$

- The transform coefficient decoding process and picture construction process prior to deblocking filter process in subclause 8.5 is invoked with pred_L and luma8x8BlkIdx as the input and the constructed samples for the current 8x8 luma block S'_L as the output.

8.3.2.1 Derivation process for Intra8x8PredMode

Inputs to this process are the index of the 8x8 luma block luma8x8BlkIdx and variable arrays Intra4x4PredMode (if available) and Intra8x8PredMode (if available) that are previously (in decoding order) derived for adjacent macroblocks.

Output of this process is the variable Intra8x8PredMode[luma8x8BlkIdx].

Table 8-3 specifies the values for Intra8x8PredMode[luma8x8BlkIdx] and the associated mnemonic names.

Table 8-3 – Specification of Intra8x8PredMode[luma8x8BlkIdx] and associated names

Intra8x8PredMode[luma8x8BlkIdx]	Name of Intra8x8PredMode[luma8x8BlkIdx]
0	Intra_8x8_Vertical (prediction mode)
1	Intra_8x8_Horizontal (prediction mode)
2	Intra_8x8_DC (prediction mode)
3	Intra_8x8_Diagonal_Down_Left (prediction mode)
4	Intra_8x8_Diagonal_Down_Right (prediction mode)
5	Intra_8x8_Vertical_Right (prediction mode)
6	Intra_8x8_Horizontal_Down (prediction mode)
7	Intra_8x8_Vertical_Left (prediction mode)
8	Intra_8x8_Horizontal_Up (prediction mode)

Intra8x8PredMode[luma8x8BlkIdx] is derived as follows.

- The process specified in subclause 6.4.8.2 is invoked with luma8x8BlkIdx given as input and the output is assigned to mbAddrA, luma8x8BlkIdxA, mbAddrB, and luma8x8BlkIdxB.
- The variable dcPredModePredictedFlag is derived as follows.
 - If any of the following conditions are true, dcPredModePredictedFlag is set equal to 1
 - the macroblock with address mbAddrA is not available
 - the macroblock with address mbAddrB is not available
 - the macroblock with address mbAddrA is available and coded in Inter prediction mode and constrained_intra_pred_flag is equal to 1

- the macroblock with address mbAddrB is available and coded in Inter prediction mode and constrained_intra_pred_flag is equal to 1
- Otherwise, dcPredModePredictedFlag is set equal to 0.
- For N being either replaced by A or B, the variables intraMxMPredModeN are derived as follows.
 - If dcPredModePredictedFlag is equal to 1 or (the macroblock with address mbAddrN is not coded in Intra_4x4 macroblock prediction mode and the macroblock with address mbAddrN is not coded in Intra_8x8 macroblock prediction mode), intraMxMPredModeN is set equal to 2 (Intra_8x8_DC prediction mode).
 - Otherwise (dcPredModePredictedFlag is equal to 0 and (the macroblock with address mbAddrN is coded in Intra_4x4 macroblock prediction mode or the macroblock with address mbAddrN is coded in Intra_8x8 macroblock prediction mode)), the following applies.
 - If the macroblock with address mbAddrN is coded in Intra_8x8 macroblock mode, intraMxMPredModeN is set equal to Intra8x8PredMode[luma8x8BlkIdxN], where Intra8x8PredMode is the variable array assigned to the macroblock mbAddrN.
 - Otherwise (the macroblock with address mbAddrN is coded in Intra_4x4 macroblock mode), intraMxMPredModeN is derived by the following procedure, where Intra4x4PredMode is the variable array assigned to the macroblock mbAddrN.

$$\text{intraMxMPredModeN} = \text{Intra4x4PredMode}[\text{luma8x8BlkIdxN} * 4 + n] \quad (8-71)$$

where the variable n is derived as follows

- If N is equal to A, depending on the variable MbaffFrameFlag, the variable luma8x8BlkIdx, the current macroblock, and the macroblock mbAddrN, the following applies.
 - If MbaffFrameFlag is equal to 1, the current macroblock is a frame coded macroblock, the macroblock mbAddrN is a field coded macroblock, and luma8x8BlkIdx is equal to 2, n is set equal to 3.
 - Otherwise (MbaffFrameFlag is equal to 0 or the current macroblock is a field coded macroblock or the macroblock mbAddrN is a frame coded macroblock or luma8x8BlkIdx is not equal to 2), n is set equal to 1.
- Otherwise (N is equal to B), n is set equal to 2.
- Finally, given intraMxMPredModeA and intraMxMPredModeB, the variable Intra8x8PredMode[luma8x8BlkIdx] is derived by applying the following procedure.

$$\begin{aligned}
 &\text{predIntra8x8PredMode} = \text{Min}(\text{intraMxMPredModeA}, \text{intraMxMPredModeB}) \\
 &\text{if}(\text{prev_intra8x8_pred_mode_flag}[\text{luma8x8BlkIdx}]) \\
 &\quad \text{Intra8x8PredMode}[\text{luma8x8BlkIdx}] = \text{predIntra8x8PredMode} \\
 &\text{else} \\
 &\quad \text{if}(\text{rem_intra8x8_pred_mode}[\text{luma8x8BlkIdx}] < \text{predIntra8x8PredMode}) \\
 &\quad \quad \text{Intra8x8PredMode}[\text{luma8x8BlkIdx}] = \text{rem_intra8x8_pred_mode}[\text{luma8x8BlkIdx}] \\
 &\quad \text{else} \\
 &\quad \quad \text{Intra8x8PredMode}[\text{luma8x8BlkIdx}] = \text{rem_intra8x8_pred_mode}[\text{luma8x8BlkIdx}] + 1
 \end{aligned} \quad (8-72)$$

8.3.2.2 Intra_8x8 sample prediction

This process is invoked for each 8x8 luma block of a macroblock with prediction mode equal to Intra_8x8 followed by the transform decoding process and picture construction process prior to deblocking for each 8x8 luma block.

Input to this process is the index of an 8x8 luma block luma8x8BlkIdx.

Output of this process are the prediction samples pred8x8L[x, y], with x, y = 0..7 for the 8x8 luma block with index luma8x8BlkIdx.

The position of the upper-left sample of an 8x8 luma block with index luma8x8BlkIdx inside the current macroblock is derived by invoking the inverse 8x8 luma block scanning process in subclause 6.4.4 with luma8x8BlkIdx as the input and the output being assigned to (xO, yO).

The 25 neighbouring samples p[x, y] that are constructed luma samples prior to the deblocking filter process, with x = -1, y = -1..7 and x = 0..15, y = -1, are derived as follows.

- The luma location (xN, yN) is specified by

$$xN = xO + x \quad (8-73)$$

$$yN = yO + y \quad (8-74)$$

- The derivation process for neighbouring locations in subclause 6.4.9 is invoked for luma locations with (xN, yN) as input and mbAddrN and (xW, yW) as output.
- Each sample p[x, y] with x = -1, y = -1..7 and x = 0..15, y = -1 is derived as follows.
 - If any of the following conditions is true, the sample p[x, y] is marked as “not available for Intra_8x8 prediction”
 - mbAddrN is not available,
 - the macroblock mbAddrN is coded in Inter prediction mode and constrained_intra_pred_flag is equal to 1,
 - Otherwise, the sample p[x, y] is marked as “available for Intra_8x8 prediction” and the luma sample at luma location (xW, yW) inside the macroblock mbAddrN is assigned to p[x, y].

When samples p[x, -1], with x = 8..15 are marked as “not available for Intra_8x8 prediction,” and the sample p[7, -1] is marked as “available for Intra_8x8 prediction,” the sample value of p[7, -1] is substituted for sample values p[x, -1], with x = 8..15 and samples p[x, -1], with x = 8..15 are marked as “available for Intra_8x8 prediction”.

NOTE – Each block is assumed to be constructed into a picture array prior to decoding of the next block.

The reference sample filtering process for Intra_8x8 sample prediction in subclause 8.3.2.2.1 is invoked with the samples p[x, y] with x = -1, y = -1..7 and x = 0..15, y = -1 (if available) as input and p'[x, y] with x = -1, y = -1..7 and x = 0..15, y = -1 as output.

Depending on Intra8x8PredMode[luma8x8BlkIdx], one of the Intra_8x8 prediction modes specified in subclauses 8.3.2.2.2 to 8.3.2.2.10 is invoked.

8.3.2.2.1 Reference sample filtering process for Intra_8x8 sample prediction

Inputs to this process are the reference samples p[x, y] with x = -1, y = -1..7 and x = 0..15, y = -1 (if available) for Intra_8x8 sample prediction.

Outputs of this process are the filtered reference samples p'[x, y] with x = -1, y = -1..7 and x = 0..15, y = -1 for Intra_8x8 sample prediction.

When all samples p[x, -1] with x = 0..7 are marked as “available for Intra_8x8 prediction”, the following applies.

- The value of p'[0, -1] is derived as follows.
 - If p[-1, -1] is marked as “available for Intra_8x8 prediction”, p'[0, -1] is derived by

$$p'[0, -1] = (p[-1, -1] + 2 * p[0, -1] + p[1, -1] + 2) >> 2 \quad (8-75)$$

- Otherwise (p[-1, -1] is marked as “not available for Intra_8x8 prediction”), p'[0, -1] is derived by

$$p'[0, -1] = (3 * p[0, -1] + p[1, -1] + 2) >> 2 \quad (8-76)$$

- The values of p'[x, -1], with x = 1..7 are derived by

$$p'[x, -1] = (p[x-1, -1] + 2 * p[x, -1] + p[x+1, -1] + 2) >> 2 \quad (8-77)$$

When all samples p[x, -1] with x = 7..15 are marked as “available for Intra_8x8 prediction”, the following applies.

- The values of p'[x, -1], with x = 8..14 are derived by

$$p'[x, -1] = (p[x-1, -1] + 2 * p[x, -1] + p[x+1, -1] + 2) >> 2 \quad (8-78)$$

- The value of p'[15, -1] is derived by

$$p'[15, -1] = (p[14, -1] + 3 * p[15, -1] + 2) >> 2 \quad (8-79)$$

When the sample $p[-1, -1]$ is marked as “available for Intra_8x8 prediction”, the value of $p'[-1, -1]$ is derived as follows.

- If the sample $p[0, -1]$ is marked as “not available for Intra_8x8 prediction” or the sample $p[-1, 0]$ is marked as “not available for Intra_8x8 prediction”, the following applies.

- If the sample $p[0, -1]$ is marked as “available for Intra_8x8 prediction”, $p'[-1, -1]$ is derived by

$$p'[-1, -1] = (3 * p[-1, -1] + p[0, -1] + 2) >> 2 \quad (8-80)$$

- Otherwise (the sample $p[0, -1]$ is marked as “not available for Intra_8x8 prediction” and the sample $p[-1, 0]$ is marked as “available for Intra_8x8 prediction”), $p'[-1, -1]$ is derived by

$$p'[-1, -1] = (3 * p[-1, -1] + p[-1, 0] + 2) >> 2 \quad (8-81)$$

- Otherwise (the sample $p[0, -1]$ is marked as “available for Intra_8x8 prediction” and the sample $p[-1, 0]$ is marked as “available for Intra_8x8 prediction”), $p'[-1, -1]$ is derived by

$$p'[-1, -1] = (p[0, -1] + 2 * p[-1, -1] + p[-1, 0] + 2) >> 2 \quad (8-82)$$

When all samples $p[-1, y]$ with $y = 0..7$ are marked as “available for Intra_8x8 prediction”, the following applies.

- The value of $p'[-1, 0]$ is derived as follows.

- If $p[-1, -1]$ is marked as “available for Intra_8x8 prediction”, $p'[-1, 0]$ is derived by

$$p'[-1, 0] = (p[-1, -1] + 2 * p[-1, 0] + p[-1, 1] + 2) >> 2 \quad (8-83)$$

- Otherwise (if $p[-1, -1]$ is marked as “not available for Intra_8x8 prediction”), $p'[-1, 0]$ is derived by

$$p'[-1, 0] = (3 * p[-1, 0] + p[-1, 1] + 2) >> 2 \quad (8-84)$$

- The values of $p'[-1, y]$, with $y = 1..6$ are derived by

$$p'[-1, y] = (p[-1, y-1] + 2 * p[-1, y] + p[-1, y+1] + 2) >> 2 \quad (8-85)$$

- The value of $p'[-1, 7]$ is derived by

$$p'[-1, 7] = (p[-1, 6] + 3 * p[-1, 7] + 2) >> 2 \quad (8-86)$$

8.3.2.2.2 Specification of Intra_8x8_Veritical prediction mode

This Intra_8x8 prediction mode is invoked when $\text{Intra8x8PredMode}[\text{luma8x8BlkIdx}]$ is equal to 0.

This mode shall be used only when the samples $p[x, -1]$ with $x = 0..7$ are marked as “available for Intra_8x8 prediction”.

The values of the prediction samples $\text{pred8x8}_L[x, y]$, with $x, y = 0..7$ are derived by

$$\text{pred8x8}_L[x, y] = p'[x, -1], \text{ with } x, y = 0..7 \quad (8-87)$$

8.3.2.2.3 Specification of Intra_8x8_Horizontal prediction mode

This Intra_8x8 prediction mode is invoked when $\text{Intra8x8PredMode}[\text{luma8x8BlkIdx}]$ is equal to 1.

This mode shall be used only when the samples $p[-1, y]$, with $y = 0..7$ are marked as “available for Intra_8x8 prediction”.

The values of the prediction samples $\text{pred8x8}_L[x, y]$, with $x, y = 0..7$ are derived by

$$\text{pred8x8}_L[x, y] = p'[-1, y], \text{ with } x, y = 0..7 \quad (8-88)$$

8.3.2.2.4 Specification of Intra_8x8_DC prediction mode

This Intra_8x8 prediction mode is invoked when Intra8x8PredMode[luma8x8BlkIdx] is equal to 2.

The values of the prediction samples $\text{pred8x8}_L[x, y]$, with $x, y = 0..7$ are derived as follows.

- If all samples $p[x, -1]$, with $x = 0..7$ and $p[-1, y]$, with $y = 0..7$ are marked as “available for Intra_8x8 prediction,” the values of the prediction samples $\text{pred8x8}_L[x, y]$, with $x, y = 0..7$ are derived by

$$\text{pred8x8}_L[x, y] = \left(\sum_{x'=0}^7 p'[x', -1] + \sum_{y'=0}^7 p'[-1, y'] + 8 \right) \gg 4 \quad (8-89)$$

- Otherwise, if any samples $p[x, -1]$, with $x = 0..7$ are marked as “not available for Intra_8x8 prediction” and all samples $p[-1, y]$, with $y = 0..7$ are marked as “available for Intra_8x8 prediction”, the values of the prediction samples $\text{pred8x8}_L[x, y]$, with $x, y = 0..7$ are derived by

$$\text{pred8x8}_L[x, y] = \left(\sum_{y'=0}^7 p'[-1, y'] + 4 \right) \gg 3 \quad (8-90)$$

- Otherwise, if any samples $p[-1, y]$, with $y = 0..7$ are marked as “not available for Intra_8x8 prediction” and all samples $p[x, -1]$, with $x = 0..7$ are marked as “available for Intra_8x8 prediction”, the values of the prediction samples $\text{pred8x8}_L[x, y]$, with $x, y = 0..7$ are derived by

$$\text{pred8x8}_L[x, y] = \left(\sum_{x'=0}^7 p'[x', -1] + 4 \right) \gg 3 \quad (8-91)$$

- Otherwise (some samples $p[x, -1]$, with $x = 0..7$ and some samples $p[-1, y]$, with $y = 0..7$ are marked as “not available for Intra_8x8 prediction”), the values of the prediction samples $\text{pred8x8}_L[x, y]$, with $x, y = 0..7$ are derived by

$$\text{pred8x8}_L[x, y] = (1 \ll (\text{BitDepth}_Y - 1)) \quad (8-92)$$

NOTE – An 8x8 luma block can always be predicted using this mode.

8.3.2.2.5 Specification of Intra_8x8_Diagonal_Down_Left prediction mode

This Intra_8x8 prediction mode is invoked when Intra8x8PredMode[luma8x8BlkIdx] is equal to 3.

This mode shall be used only when the samples $p[x, -1]$ with $x = 0..15$ are marked as “available for Intra_8x8 prediction”.

The values of the prediction samples $\text{pred8x8}_L[x, y]$, with $x, y = 0..7$ are derived as follows.

- If x is equal to 7 and y is equal to 7,

$$\text{pred8x8}_L[x, y] = (p[14, -1] + 3 * p[15, -1] + 2) \gg 2 \quad (8-93)$$

- Otherwise (x is not equal to 7 or y is not equal to 7),

$$\text{pred8x8}_L[x, y] = (p[x + y, -1] + 2 * p[x + y + 1, -1] + p[x + y + 2, -1] + 2) \gg 2 \quad (8-94)$$

8.3.2.2.6 Specification of Intra_8x8_Diagonal_Down_Right prediction mode

This Intra_8x8 prediction mode is invoked when Intra8x8PredMode[luma8x8BlkIdx] is equal to 4.

This mode shall be used only when the samples $p[x, -1]$ with $x = 0..7$ and $p[-1, y]$ with $y = -1..7$ are marked as “available for Intra_8x8 prediction”.

The values of the prediction samples $\text{pred8x8}_L[x, y]$, with $x, y = 0..7$ are derived as follows.

- If x is greater than y ,

$$\text{pred8x8}_L[x, y] = (p[x - y - 2, -1] + 2 * p[x - y - 1, -1] + p[x - y, -1] + 2) \gg 2 \quad (8-95)$$

- Otherwise if x is less than y,

$$\text{pred8x8}_L[x, y] = (p'[-1, y - x - 2] + 2 * p'[-1, y - x - 1] + p'[-1, y - x] + 2) \gg 2 \quad (8-96)$$

- Otherwise (x is equal to y),

$$\text{pred8x8}_L[x, y] = (p'[0, -1] + 2 * p'[-1, -1] + p'[-1, 0] + 2) \gg 2 \quad (8-97)$$

8.3.2.2.7 Specification of Intra_8x8_Vertical_Right prediction mode

This Intra_8x8 prediction mode is invoked when Intra8x8PredMode[luma8x8BlkIdx] is equal to 5.

This mode shall be used only when the samples $p[x, -1]$ with $x = 0..7$ and $p[-1, y]$ with $y = -1..7$ are marked as “available for Intra_8x8 prediction”.

Let the variable zVR be set equal to $2 * x - y$.

The values of the prediction samples $\text{pred8x8}_L[x, y]$, with $x, y = 0..7$ are derived as follows.

- If zVR is equal to 0, 2, 4, 6, 8, 10, 12, or 14

$$\text{pred8x8}_L[x, y] = (p'[x - (y \gg 1) - 1, -1] + p'[x - (y \gg 1), -1] + 1) \gg 1 \quad (8-98)$$

- Otherwise, if zVR is equal to 1, 3, 5, 7, 9, 11, or 13

$$\text{pred8x8}_L[x, y] = (p'[x - (y \gg 1) - 2, -1] + 2 * p'[x - (y \gg 1) - 1, -1] + p'[x - (y \gg 1), -1] + 2) \gg 2 \quad (8-99)$$

- Otherwise, if zVR is equal to -1,

$$\text{pred8x8}_L[x, y] = (p'[-1, 0] + 2 * p'[-1, -1] + p'[0, -1] + 2) \gg 2 \quad (8-100)$$

- Otherwise (zVR is equal to -2, -3, -4, -5, -6, or -7),

$$\text{pred8x8}_L[x, y] = (p'[-1, y - 2*x - 1] + 2 * p'[-1, y - 2*x - 2] + p'[-1, y - 2*x - 3] + 2) \gg 2 \quad (8-101)$$

8.3.2.2.8 Specification of Intra_8x8_Horizontal_Down prediction mode

This Intra_8x8 prediction mode is invoked when Intra8x8PredMode[luma8x8BlkIdx] is equal to 6.

This mode shall be used only when the samples $p[x, -1]$ with $x = 0..7$ and $p[-1, y]$ with $y = -1..7$ are marked as “available for Intra_8x8 prediction”.

Let the variable zHD be set equal to $2 * y - x$.

The values of the prediction samples $\text{pred8x8}_L[x, y]$, with $x, y = 0..7$ are derived as follows.

- If zHD is equal to 0, 2, 4, 6, 8, 10, 12, or 14

$$\text{pred8x8}_L[x, y] = (p'[-1, y - (x \gg 1) - 1] + p'[-1, y - (x \gg 1)] + 1) \gg 1 \quad (8-102)$$

- Otherwise, if zHD is equal to 1, 3, 5, 7, 9, 11, or 13

$$\text{pred8x8}_L[x, y] = (p'[-1, y - (x \gg 1) - 2] + 2 * p'[-1, y - (x \gg 1) - 1] + p'[-1, y - (x \gg 1)] + 2) \gg 2 \quad (8-103)$$

- Otherwise, if zHD is equal to -1,

$$\text{pred8x8}_L[x, y] = (p'[-1, 0] + 2 * p'[-1, -1] + p'[0, -1] + 2) \gg 2 \quad (8-104)$$

- Otherwise (zHD is equal to -2, -3, -4, -5, -6, -7),

$$\text{pred8x8}_L[x, y] = (p'[x - 2*y - 1, -1] + 2 * p'[x - 2*y - 2, -1] + p'[x - 2*y - 3, -1] + 2) \gg 2 \quad (8-105)$$

8.3.2.2.9 Specification of Intra_8x8_Vertical_Left prediction mode

This Intra_8x8 prediction mode is invoked when Intra8x8PredMode[luma8x8BlkIdx] is equal to 7.

This mode shall be used only when the samples $p[x, -1]$ with $x = 0..15$ are marked as “available for Intra_8x8 prediction”.

The values of the prediction samples $\text{pred8x8}_L[x, y]$, with $x, y = 0..7$ are derived as follows.

- If y is equal to 0, 2, 4 or 6

$$\text{pred8x8}_L[x, y] = (p'[x + (y >> 1), -1] + p'[x + (y >> 1) + 1, -1] + 1) >> 1 \quad (8-106)$$

- Otherwise (y is equal to 1, 3, 5, 7),

$$\text{pred8x8}_L[x, y] = (p'[x + (y >> 1), -1] + 2 * p'[x + (y >> 1) + 1, -1] + p'[x + (y >> 1) + 2, -1] + 2) >> 2 \quad (8-107)$$

8.3.2.2.10 Specification of Intra_8x8_Horizontal_Up prediction mode

This Intra_8x8 prediction mode is invoked when Intra8x8PredMode[luma8x8BlkIdx] is equal to 8.

This mode shall be used only when the samples $p[-1, y]$ with $y = 0..7$ are marked as “available for Intra_8x8 prediction”.

Let the variable zHU be set equal to $x + 2 * y$.

The values of the prediction samples $\text{pred8x8}_L[x, y]$, with $x, y = 0..7$ are derived as follows:

- If zHU is equal to 0, 2, 4, 6, 8, 10, or 12

$$\text{pred8x8}_L[x, y] = (p'[-1, y + (x >> 1)] + p'[-1, y + (x >> 1) + 1] + 1) >> 1 \quad (8-108)$$

- Otherwise, if zHU is equal to 1, 3, 5, 7, 9, or 11

$$\text{pred8x8}_L[x, y] = (p'[-1, y + (x >> 1)] + 2 * p'[-1, y + (x >> 1) + 1] + p'[-1, y + (x >> 1) + 2] + 2) >> 2 \quad (8-109)$$

- Otherwise, if zHU is equal to 13,

$$\text{pred8x8}_L[x, y] = (p'[-1, 6] + 3 * p'[-1, 7] + 2) >> 2 \quad (8-110)$$

- Otherwise (zHU is greater than 13),

$$\text{pred8x8}_L[x, y] = p'[-1, 7] \quad (8-111)$$

8.3.3 Intra_16x16 prediction process for luma samples

This process is invoked when the macroblock prediction mode is equal to Intra_16x16. It specifies how the Intra prediction luma samples for the current macroblock are derived.

Outputs of this process are Intra prediction luma samples for the current macroblock $\text{pred}_L[x, y]$.

The 33 neighbouring samples $p[x, y]$ that are constructed luma samples prior to the deblocking filter process, with $x = -1, y = -1..15$ and with $x = 0..15, y = -1$, are derived as follows.

- The derivation process for neighbouring locations in subclause 6.4.9 is invoked for luma locations with (x, y) assigned to (xN, yN) as input and mbAddrN and (xW, yW) as output.
- Each sample $p[x, y]$ with $x = -1, y = -1..15$ and with $x = 0..15, y = -1$ is derived as follows.
 - If any of the following conditions is true, the sample $p[x, y]$ is marked as “not available for Intra_16x16 prediction”
 - mbAddrN is not available,
 - the macroblock mbAddrN is coded in Inter prediction mode and $\text{constrained_intra_pred_flag}$ is equal to 1.

- the macroblock mbAddrN has mb_type equal to SI and constrained_intra_pred_flag is equal to 1.
- Otherwise, the sample $p[x, y]$ is marked as “available for Intra_16x16 prediction” and the luma sample at luma location (xW, yW) inside the macroblock mbAddrN is assigned to $p[x, y]$.

Let $\text{pred}_L[x, y]$ with $x, y = 0..15$ denote the prediction samples for the 16x16 luma block samples.

Intra_16x16 prediction modes are specified in Table 8-4.

Table 8-4 – Specification of Intra16x16PredMode and associated names

Intra16x16PredMode	Name of Intra16x16PredMode
0	Intra_16x16_Vertical (prediction mode)
1	Intra_16x16_Horizontal (prediction mode)
2	Intra_16x16_DC (prediction mode)
3	Intra_16x16_Plane (prediction mode)

Depending on Intra16x16PredMode, one of the Intra_16x16 prediction modes specified in subclauses 8.3.3.1 to 8.3.3.4 is invoked.

8.3.3.1 Specification of Intra_16x16_Vertical prediction mode

This Intra_16x16 prediction mode shall be used only when the samples $p[x, -1]$ with $x = 0..15$ are marked as “available for Intra_16x16 prediction”.

$$\text{pred}_L[x, y] = p[x, -1], \text{ with } x, y = 0..15 \quad (8-112)$$

8.3.3.2 Specification of Intra_16x16_Horizontal prediction mode

This Intra_16x16 prediction mode shall be used only when the samples $p[-1, y]$ with $y = 0..15$ are marked as “available for Intra_16x16 prediction”.

$$\text{pred}_L[x, y] = p[-1, y], \text{ with } x, y = 0..15 \quad (8-113)$$

8.3.3.3 Specification of Intra_16x16_DC prediction mode

This Intra_16x16 prediction mode operates, depending on whether the neighbouring samples are marked as “available for Intra_16x16 prediction”, as follows.

- If all neighbouring samples $p[x, -1]$, with $x = 0..15$ and $p[-1, y]$, with $y = 0..15$ are marked as “available for Intra_16x16 prediction”, the prediction for all luma samples in the macroblock is given by:

$$\text{pred}_L[x, y] = \left(\sum_{x'=0}^{15} p[x', -1] + \sum_{y'=0}^{15} p[-1, y'] + 16 \right) \gg 5, \text{ with } x, y = 0..15 \quad (8-114)$$

- Otherwise, if any of the neighbouring samples $p[x, -1]$, with $x = 0..15$ are marked as "not available for Intra_16x16 prediction" and all of the neighbouring samples $p[-1, y]$, with $y = 0..15$ are marked as “available for Intra_16x16 prediction”, the prediction for all luma samples in the macroblock is given by:

$$\text{pred}_L[x, y] = \left(\sum_{y'=0}^{15} p[-1, y'] + 8 \right) \gg 4, \text{ with } x, y = 0..15 \quad (8-115)$$

- Otherwise, if any of the neighbouring samples $p[-1, y]$, with $y = 0..15$ are marked as "not available for Intra_16x16 prediction" and all of the neighbouring samples $p[x, -1]$, with $x = 0..15$ are marked as “available for Intra_16x16 prediction”, the prediction for all luma samples in the macroblock is given by:

$$\text{pred}_L[x, y] = \left(\sum_{x'=0}^{15} p[x', -1] + 8 \right) \gg 4, \text{ with } x, y = 0..15 \quad (8-116)$$

- Otherwise (some of the neighbouring samples $p[x, -1]$, with $x = 0..15$ and some of the neighbouring samples $p[-1, y]$, with $y = 0..15$ are marked as “not available for Intra_16x16 prediction”), the prediction for all luma samples in the macroblock is given by:

$$\text{pred}_L[x, y] = (1 \ll (\text{BitDepth}_Y - 1)), \text{ with } x, y = 0..15 \quad (8-117)$$

8.3.3.4 Specification of Intra_16x16_Plane prediction mode

This Intra_16x16 prediction mode shall be used only when the samples $p[x, -1]$ with $x = -1..15$ and $p[-1, y]$ with $y = 0..15$ are marked as “available for Intra_16x16 prediction”.

$$\text{pred}_L[x, y] = \text{Clip1}_Y((a + b * (x - 7) + c * (y - 7) + 16) \gg 5), \text{ with } x, y = 0..15, \quad (8-118)$$

where:

$$a = 16 * (p[-1, 15] + p[15, -1]) \quad (8-119)$$

$$b = (5 * H + 32) \gg 6 \quad (8-120)$$

$$c = (5 * V + 32) \gg 6 \quad (8-121)$$

and H and V are specified in Equations 8-122 and 8-123.

$$H = \sum_{x'=0}^7 (x'+1) * (p[8+x', -1] - p[6-x', -1]) \quad (8-122)$$

$$V = \sum_{y'=0}^7 (y'+1) * (p[-1, 8+y'] - p[-1, 6-y']) \quad (8-123)$$

8.3.4 Intra prediction process for chroma samples

This process is invoked for I and SI macroblock types. It specifies how the Intra prediction chroma samples for the current macroblock are derived.

Outputs of this process are Intra prediction chroma samples for the current macroblock $\text{pred}_{Cb}[x, y]$ and $\text{pred}_{Cr}[x, y]$.

Both chroma blocks (Cb and Cr) of the macroblock use the same prediction mode. The prediction mode is applied to each of the chroma blocks separately. The process specified in this subclause is invoked for each chroma block. In the remainder of this subclause, chroma block refers to one of the two chroma blocks and the subscript C is used as a replacement of the subscript Cb or Cr.

The neighbouring samples $p[x, y]$ that are constructed chroma samples prior to the deblocking filter process, with $x = -1, y = -1..MbHeightC - 1$ and with $x = 0..MbWidthC - 1, y = -1$, are derived as follows.

- The derivation process for neighbouring locations in subclause 6.4.9 is invoked for chroma locations with (x, y) assigned to (xN, yN) as input and $mbAddrN$ and (xW, yW) as output.
- Each sample $p[x, y]$ is derived as follows.
 - If any of the following conditions is true, the sample $p[x, y]$ is marked as “not available for Intra chroma prediction”
 - $mbAddrN$ is not available,
 - the macroblock $mbAddrN$ is coded in Inter prediction mode and $\text{constrained_intra_pred_flag}$ is equal to 1.
 - the macroblock $mbAddrN$ has mb_type equal to SI and $\text{constrained_intra_pred_flag}$ is equal to 1 and the current macroblock does not have mb_type equal to SI.
 - Otherwise, the sample $p[x, y]$ is marked as “available for Intra chroma prediction” and the chroma sample of component C at chroma location (xW, yW) inside the macroblock $mbAddrN$ is assigned to $p[x, y]$.

Let $\text{pred}_C[x, y]$ with $x = 0..MbWidthC - 1$, $y = 0..MbHeightC - 1$ denote the prediction samples for the chroma block samples.

Intra chroma prediction modes are specified in Table 8-5.

Table 8-5 – Specification of Intra chroma prediction modes and associated names

intra_chroma_pred_mode	Name of intra_chroma_pred_mode
0	Intra_Chroma_DC (prediction mode)
1	Intra_Chroma_Horizontal (prediction mode)
2	Intra_Chroma_Vertical (prediction mode)
3	Intra_Chroma_Plane (prediction mode)

Depending on `intra_chroma_pred_mode`, one of the Intra chroma prediction modes specified in subclauses 8.3.4.1 to 8.3.4.4 is invoked.

8.3.4.1 Specification of Intra_Chroma_DC prediction mode

This Intra chroma prediction mode is invoked when `intra_chroma_pred_mode` is equal to 0.

For each chroma block of 4x4 samples indexed by `chroma4x4BlkIdx = 0..(1 << (chroma_format_idc + 1)) - 1`, the following applies.

- Depending on `chroma_format_idc`, the position of the upper-left sample of a 4x4 chroma block with index `chroma4x4BlkIdx` is derived as follows

- If `chroma_format_idc` is equal to 1 or 2, the following applies

$$xO = \text{InverseRasterScan}(\text{chroma4x4BlkIdx}, 4, 4, 8, 0) \quad (8-124)$$

$$yO = \text{InverseRasterScan}(\text{chroma4x4BlkIdx}, 4, 4, 8, 1) \quad (8-125)$$

- Otherwise (`chroma_format_idc` is equal to 3), the following applies

$$xO = \text{InverseRasterScan}(\text{chroma4x4BlkIdx} / 4, 8, 8, 16, 0) + \text{InverseRasterScan}(\text{chroma4x4BlkIdx} \% 4, 4, 4, 8, 0) \quad (8-126)$$

$$yO = \text{InverseRasterScan}(\text{chroma4x4BlkIdx} / 4, 8, 8, 16, 1) + \text{InverseRasterScan}(\text{chroma4x4BlkIdx} \% 4, 4, 4, 8, 1) \quad (8-127)$$

- If (xO, yO) is equal to $(0, 0)$ or xO and yO are greater than 0, the values of the prediction samples $\text{pred}_C[x + xO, y + yO]$ with $x, y = 0..3$ are derived as follows.

- If all samples $p[x + xO, -1]$, with $x = 0..3$ and $p[-1, y + yO]$, with $y = 0..3$ are marked as “available for Intra chroma prediction”, the values of the prediction samples $\text{pred}_C[x + xO, y + yO]$, with $x, y = 0..3$ are derived as

$$\text{pred}_C[x + xO, y + yO] = \left(\sum_{x'=0}^3 p[x' + xO, -1] + \sum_{y'=0}^3 p[-1, y' + yO] + 4 \right) >> 3, \text{ with } x, y = 0..3. \quad (8-128)$$

- Otherwise, if any samples $p[x + xO, -1]$, with $x = 0..3$ are marked as “not available for Intra chroma prediction” and all samples $p[-1, y + yO]$, with $y = 0..3$ are marked as “available for Intra chroma prediction”, the values of the prediction samples $\text{pred}_C[x + xO, y + yO]$, with $x, y = 0..3$ are derived as

$$\text{pred}_C[x + xO, y + yO] = \left(\sum_{y'=0}^3 p[-1, y' + yO] + 2 \right) >> 2, \text{ with } x, y = 0..3. \quad (8-129)$$

- Otherwise, if any samples $p[-1, y+yO]$, with $y = 0..3$ are marked as “not available for Intra chroma prediction” and all samples $p[x+xO, -1]$, with $x = 0..3$ are marked as “available for Intra chroma prediction”, the values of the prediction samples $pred_C[x+xO, y+yO]$, with $x, y = 0..3$ are derived as

$$pred_C[x+xO, y+yO] = \left(\sum_{x'=0}^3 p[x'+xO, -1] + 2 \right) \gg 2, \text{ with } x, y = 0..3. \quad (8-130)$$

- Otherwise (some samples $p[x+xO, -1]$, with $x = 0..3$ and some samples $p[-1, y+yO]$, with $y = 0..3$ are marked as “not available for Intra chroma prediction”), the values of the prediction samples $pred_C[x+xO, y+yO]$, with $x, y = 0..3$ are derived as

$$pred_C[x+xO, y+yO] = (1 \ll (\text{BitDepth}_C - 1)), \text{ with } x, y = 0..3. \quad (8-131)$$

- Otherwise, if xO is greater than 0 and yO is equal to 0, the values of the prediction samples $pred_C[x+xO, y+yO]$ with $x, y = 0..3$ are derived as follows.

- If all samples $p[x+xO, -1]$, with $x = 0..3$ are marked as “available for Intra chroma prediction”, the values of the prediction samples $pred_C[x+xO, y+yO]$, with $x, y = 0..3$ are derived as

$$pred_C[x+xO, y+yO] = \left(\sum_{x'=0}^3 p[x'+xO, -1] + 2 \right) \gg 2, \text{ with } x, y = 0..3. \quad (8-132)$$

- Otherwise, if all samples $p[-1, y+yO]$, with $y = 0..3$ are marked as “available for Intra chroma prediction”, the values of the prediction samples $pred_C[x+xO, y+yO]$, with $x, y = 0..3$ are derived as

$$pred_C[x+xO, y+yO] = \left(\sum_{y'=0}^3 p[-1, y'+yO] + 2 \right) \gg 2, \text{ with } x, y = 0..3. \quad (8-133)$$

- Otherwise (some samples $p[x+xO, -1]$, with $x = 0..3$ and some samples $p[-1, y+yO]$, with $y = 0..3$ are marked as “not available for Intra chroma prediction”), the values of the prediction samples $pred_C[x+xO, y+yO]$, with $x, y = 0..3$ are derived as

$$pred_C[x+xO, y+yO] = (1 \ll (\text{BitDepth}_C - 1)), \text{ with } x, y = 0..3. \quad (8-134)$$

- Otherwise (xO is equal to 0 and yO is greater than 0), the values of the prediction samples $pred_C[x+xO, y+yO]$ with $x, y = 0..3$ are derived as follows.

- If all samples $p[-1, y+yO]$, with $y = 0..3$ are marked as “available for Intra chroma prediction”, the values of the prediction samples $pred_C[x+xO, y+yO]$, with $x, y = 0..3$ are derived as

$$pred_C[x+xO, y+yO] = \left(\sum_{y'=0}^3 p[-1, y'+yO] + 2 \right) \gg 2, \text{ with } x, y = 0..3. \quad (8-135)$$

- Otherwise, if all samples $p[x+xO, -1]$, with $x = 0..3$ are marked as “available for Intra chroma prediction”, the values of the prediction samples $pred_C[x+xO, y+yO]$, with $x, y = 0..3$ are derived as

$$pred_C[x+xO, y+yO] = \left(\sum_{x'=0}^3 p[x'+xO, -1] + 2 \right) \gg 2, \text{ with } x, y = 0..3. \quad (8-136)$$

- Otherwise (some samples $p[x+xO, -1]$, with $x = 0..3$ and some samples $p[-1, y+yO]$, with $y = 0..3$ are marked as “not available for Intra chroma prediction”), the values of the prediction samples $pred_C[x+xO, y+yO]$, with $x, y = 0..3$ are derived as

$$pred_C[x+xO, y+yO] = (1 \ll (\text{BitDepth}_C - 1)), \text{ with } x, y = 0..3. \quad (8-137)$$

8.3.4.2 Specification of Intra_Chroma_Horizontal prediction mode

This Intra chroma prediction mode is invoked when `intra_chroma_pred_mode` is equal to 1.

This mode shall be used only when the samples `p[-1, y]` with `y = 0..MbHeightC - 1` are marked as "available for Intra chroma prediction".

The values of the prediction samples `predC[x, y]` are derived as follows.

$$\text{pred}_C[x, y] = p[-1, y], \text{ with } x = 0..MbWidthC - 1 \text{ and } y = 0..MbHeightC - 1 \quad (8-138)$$

8.3.4.3 Specification of Intra_Chroma_Vertical prediction mode

This Intra chroma prediction mode is invoked when `intra_chroma_pred_mode` is equal to 2.

This mode shall be used only when the samples `p[x, -1]` with `x = 0..MbWidthC - 1` are marked as "available for Intra chroma prediction".

The values of the prediction samples `predC[x, y]` are derived as follows.

$$\text{pred}_C[x, y] = p[x, -1], \text{ with } x = 0..MbWidthC - 1 \text{ and } y = 0..MbHeightC - 1 \quad (8-139)$$

8.3.4.4 Specification of Intra_Chroma_Plane prediction mode

This Intra chroma prediction mode is invoked when `intra_chroma_pred_mode` is equal to 3.

This mode shall be used only when the samples `p[x, -1]`, with `x = 0..MbWidthC - 1` and `p[-1, y]`, with `y = -1..MbHeightC - 1` are marked as "available for Intra chroma prediction".

The values of the prediction samples `predC[x, y]` are derived as follows.

Let the variable `xCF` be set equal to `4 * (chroma_format_idc == 3)` and let the variable `yCF` be set equal to `4 * (chroma_format_idc != 1)`.

$$\text{pred}_C[x, y] = \text{Clip1}_C((a + b * (x - 3 - xCF) + c * (y - 3 - yCF) + 16) \gg 5), \\ \text{with } x = 0..MbWidthC - 1 \text{ and } y = 0..MbHeightC - 1 \quad (8-140)$$

where:

$$a = 16 * (p[-1, MbHeightC - 1] + p[MbWidthC - 1, -1]) \quad (8-141)$$

$$b = ((34 - 29 * (chroma_format_idc == 3)) * H + 32) \gg 6 \quad (8-142)$$

$$c = ((34 - 29 * (chroma_format_idc != 1)) * V + 32) \gg 6 \quad (8-143)$$

and `H` and `V` are specified as

$$H = \sum_{x'=0}^{3+xCF} (x'+1) * (p[4+xCF+x', -1] - p[2+xCF-x', -1]) \quad (8-144)$$

$$V = \sum_{y'=0}^{3+yCF} (y'+1) * (p[-1, 4+yCF+y'] - p[-1, 2+yCF-y']) \quad (8-145)$$

8.3.5 Sample construction process for I_PCM macroblocks

This process is invoked when `mb_type` is equal to `I_PCM`.

The variable `dy` is derived as follows.

- If `MbaffFrameFlag` is equal to 1 and the current macroblock is a field macroblock, `dy` is set equal to 2.
- Otherwise (`MbaffFrameFlag` is equal to 0 or the current macroblock is a frame macroblock), `dy` is set equal to 1.

The position of the upper-left luma sample of the current macroblock is derived by invoking the inverse macroblock scanning process in subclause 6.4.1 with CurrMbAddr as input and the output being assigned to (xP, yP).

The constructed luma samples prior to the deblocking process are generated as specified by:

$$\text{for}(i = 0; i < 256; i++) \\ S'_{L}[xP + (i \% 16), yP + dy * (i / 16)] = \text{pcm_sample_luma}[i] \quad (8-146)$$

When chroma_format_idc is not equal to 0 (monochrome), the constructed chroma samples prior to the deblocking process are generated as specified by:

$$\begin{aligned} &\text{for}(i = 0; i < \text{MbWidthC} * \text{MbHeightC}; i++) \{ \\ &\quad S'_{Cb}[(xP / \text{SubWidthC}) + (i \% \text{MbWidthC}), \\ &\quad \quad ((yP + \text{SubHeightC} - 1) / \text{SubHeightC}) + dy * (i / \text{MbWidthC})] = \\ &\quad \quad \text{pcm_sample_chroma}[i] \\ &\quad S'_{Cr}[(xP / \text{SubWidthC}) + (i \% \text{MbWidthC}), \\ &\quad \quad ((yP + \text{SubHeightC} - 1) / \text{SubHeightC}) + dy * (i / \text{MbWidthC})] = \\ &\quad \quad \text{pcm_sample_chroma}[i + \text{MbWidthC} * \text{MbHeightC}] \\ &\} \end{aligned} \quad (8-147)$$

8.4 Inter prediction process

This process is invoked when decoding P and B macroblock types.

Outputs of this process are Inter prediction samples for the current macroblock that are a 16x16 array pred_L of luma samples and when chroma_format_idc is not equal to 0 (monochrome) two 8x8 arrays pred_{Cr} and pred_{Cb} of chroma samples, one for each of the chroma components Cb and Cr.

The partitioning of a macroblock is specified by mb_type. Each macroblock partition is referred to by mbPartIdx. When the macroblock partitioning consists of partitions that are equal to sub-macroblocks, each sub-macroblock can be further partitioned into sub-macroblock partitions as specified by sub_mb_type. Each sub-macroblock partition is referred to by subMbPartIdx. When the macroblock partitioning does not consist of sub-macroblocks, subMbPartIdx is set equal to 0.

The following steps are specified for each macroblock partition or for each sub-macroblock partition.

The functions MbPartWidth(), MbPartHeight(), SubMbPartWidth(), and SubMbPartHeight() describing the width and height of macroblock partitions and sub-macroblock partitions are specified in Tables 7-13, 7-14, 7-17, and 7-18.

The range of the macroblock partition index mbPartIdx is derived as follows.

- If mb_type is equal to B_Skip or B_Direct_16x16, mbPartIdx proceeds over values 0..3.
- Otherwise (mb_type is not equal to B_Skip or B_Direct_16x16), mbPartIdx proceeds over values 0..NumMbPart(mb_type) – 1.

For each value of mbPartIdx, the variables partWidth and partHeight for each macroblock partition or sub-macroblock partition in the macroblock are derived as follows.

- If mb_type is not equal to P_8x8, P_8x8ref0, B_Skip, B_Direct_16x16, or B_8x8, subMbPartIdx is set equal to 0, and partWidth and partHeight are derived as

$$\text{partWidth} = \text{MbPartWidth}(\text{mb_type}) \quad (8-148)$$

$$\text{partHeight} = \text{MbPartHeight}(\text{mb_type}) \quad (8-149)$$

- Otherwise, if mb_type is equal to P_8x8 or P_8x8ref0, or mb_type is equal to B_8x8 and sub_mb_type[mbPartIdx] is not equal to B_Direct_8x8, subMbPartIdx proceeds over values 0..NumSubMbPart(sub_mb_type) – 1, and partWidth and partHeight are derived as

$$\text{partWidth} = \text{SubMbPartWidth}(\text{sub_mb_type}[\text{mbPartIdx}]) \quad (8-150)$$

$$\text{partHeight} = \text{SubMbPartHeight}(\text{sub_mb_type}[\text{mbPartIdx}]). \quad (8-151)$$

- Otherwise (mb_type is equal to B_Skip or B_Direct_16x16, or mb_type is equal to B_8x8 and sub_mb_type[mbPartIdx] is equal to B_Direct_8x8), subMbPartIdx proceeds over values 0..3, and partWidth and partHeight are derived as

$$\text{partWidth} = 4 \quad (8-152)$$

$$\text{partHeight} = 4 \quad (8-153)$$

When chroma_format_idc is not equal to 0 (monochrome) the variables partWidthC and partHeightC are derived as

$$\text{partWidthC} = \text{partWidth} / \text{SubWidthC} \quad (8-154)$$

$$\text{partHeightC} = \text{partHeight} / \text{SubHeightC} \quad (8-155)$$

Let the variable MvCnt be initially set equal to 0 before any invocation of subclause 8.4.1 for the macroblock.

The Inter prediction process for a macroblock partition mbPartIdx and a sub-macroblock partition subMbPartIdx consists of the following ordered steps

1. Derivation process for motion vector components and reference indices as specified in subclause 8.4.1.

Inputs to this process are

- a macroblock partition mbPartIdx,
- a sub-macroblock partition subMbPartIdx.

Outputs of this process are

- luma motion vectors mvL0 and mvL1 and when chroma_format_idc is not equal to 0 (monochrome) the chroma motion vectors mvCL0 and mvCL1
- reference indices refIdxL0 and refIdxL1
- prediction list utilization flags predFlagL0 and predFlagL1
- the sub-macroblock partition motion vector count subMvCnt.

2. The variable MvCnt is incremented by subMvCnt.

3. Decoding process for Inter prediction samples as specified in subclause 8.4.2.

Inputs to this process are

- a macroblock partition mbPartIdx,
- a sub-macroblock partition subMbPartIdx.
- variables specifying partition width and height for luma and chroma (if available), partWidth, partHeight, partWidthC (if available), and partHeightC (if available)
- luma motion vectors mvL0 and mvL1 and when chroma_format_idc is not equal to 0 (monochrome) the chroma motion vectors mvCL0 and mvCL1
- reference indices refIdxL0 and refIdxL1
- prediction list utilization flags predFlagL0 and predFlagL1

Outputs of this process are

- inter prediction samples (pred); which are a (partWidth)x(partHeight) array predPart_L of prediction luma samples and when chroma_format_idc is not equal to 0 (monochrome) two (partWidthC)x(partHeightC) arrays predPart_{Cb}, and predPart_{Cr} of prediction chroma samples, one for each of the chroma components Cb and Cr.

For use in derivation processes of variables invoked later in the decoding process, the following assignments are made:

$$\text{MvL0}[\text{mbPartIdx}][\text{subMbPartIdx}] = \text{mvL0} \quad (8-156)$$

$$\text{MvL1}[\text{mbPartIdx}][\text{subMbPartIdx}] = \text{mvL1} \quad (8-157)$$

$$\text{RefIdxL0}[\text{mbPartIdx}] = \text{refIdxL0} \quad (8-158)$$

$$\text{RefIdxL1}[\text{mbPartIdx}] = \text{refIdxL1} \quad (8-159)$$

$$\text{PredFlagL0}[\text{mbPartIdx}] = \text{predFlagL0} \quad (8-160)$$

$$\text{PredFlagL1}[\text{mbPartIdx}] = \text{predFlagL1} \quad (8-161)$$

The location of the upper-left sample of the partition relative to the upper-left sample of the macroblock is derived by invoking the inverse macroblock partition scanning process as described in subclause 6.4.2.1 with `mbPartIdx` as the input and `(xP, yP)` as the output.

The location of the upper-left sample of the macroblock sub-partition relative to the upper-left sample of the macroblock partition is derived by invoking the inverse sub-macroblock partition scanning process as described in subclause 6.4.2.2 with `subMbPartIdx` as the input and `(xS, yS)` as the output.

The macroblock prediction is formed by placing the partition or sub-macroblock partition prediction samples in their correct relative positions in the macroblock, as follows.

The variable `predL[xP + xS + x, yP + yS + y]` with `x = 0 .. partWidth - 1`, `y = 0 .. partHeight - 1` is derived by

$$\text{predL}[\text{xP} + \text{xS} + \text{x}, \text{yP} + \text{yS} + \text{y}] = \text{predPartL}[\text{x}, \text{y}] \quad (8-162)$$

When `chroma_format_idc` is not equal to 0 (monochrome) the variable `predC` with `x = 0..partWidthC - 1`, `y = 0..partHeightC - 1`, and C in `predC` and `predPartC` being replaced by Cb or Cr is derived by

$$\text{predC}[\text{xP} / \text{SubWidthC} + \text{xS} / \text{SubWidthC} + \text{x}, \text{yP} / \text{SubHeightC} + \text{yS} / \text{SubHeightC} + \text{y}] = \text{predPartC}[\text{x}, \text{y}] \quad (8-163)$$

8.4.1 Derivation process for motion vector components and reference indices

Inputs to this process are

- a macroblock partition `mbPartIdx`,
- a sub-macroblock partition `subMbPartIdx`.

Outputs of this process are

- luma motion vectors `mvL0` and `mvL1` as well as the chroma motion vectors `mvCL0` and `mvCL1`
- reference indices `refIdxL0` and `refIdxL1`
- prediction list utilization flags `predFlagL0` and `predFlagL1`
- a sub-partition macroblock motion vector count variable `subMvCnt`

For the derivation of the variables `mvL0` and `mvL1` as well as `refIdxL0` and `refIdxL1`, the following applies.

- If `mb_type` is equal to `P_Skip`, the derivation process for luma motion vectors for skipped macroblocks in P and SP slices in subclause 8.4.1.1 is invoked with the output being the luma motion vectors `mvL0` and reference indices `refIdxL0`, and `predFlagL0` is set equal to 1. `mvL1` and `refIdxL1` are marked as not available and `predFlagL1` is set equal to 0. The sub-partition motion vector count variable `subMvCnt` is set equal to 1.
- Otherwise, if `mb_type` is equal to `B_Skip` or `B_Direct_16x16` or `sub_mb_type[mbPartIdx]` is equal to `B_Direct_8x8`, the derivation process for luma motion vectors for `B_Skip`, `B_Direct_16x16`, and `B_Direct_8x8` in B slices in subclause 8.4.1.2 is invoked with `mbPartIdx` and `subMbPartIdx` as the input and the output being the luma motion vectors `mvL0`, `mvL1`, the reference indices `refIdxL0`, `refIdxL1`, the sub-partition motion vector count `subMvCnt`, and the prediction utilization flags `predFlagL0` and `predFlagL1`.
- Otherwise, for X being replaced by either 0 or 1 in the variables `predFlagLX`, `mvLX`, `refIdxLX`, and in `Pred_LX` and in the syntax elements `ref_idx_IX` and `mvd_IX`, the following applies.

1. The variables refIdxLX and predFlagLX are derived as follows.

- If MbPartPredMode(mb_type, mbPartIdx) or SubMbPredMode(sub_mb_type[mbPartIdx]) is equal to Pred_LX or to BiPred,

$$\text{refIdxLX} = \text{ref_idx_lX}[\text{mbPartIdx}] \quad (8-164)$$

$$\text{predFlagLX} = 1 \quad (8-165)$$

- Otherwise, the variables refIdxLX and predFlagLX are specified by

$$\text{refIdxLX} = -1 \quad (8-166)$$

$$\text{predFlagLX} = 0 \quad (8-167)$$

2. The variable subMvCnt for sub-partition motion vector count is set equal to predFlagL0 + predFlagL1.

3. The variable currSubMbType is derived as follows.

- If the macroblock type is equal to B_8x8, currSubMbType is set equal to sub_mb_type[mbPartIdx].
- Otherwise (the macroblock type is not equal to B_8x8), currSubMbType is set equal to "na".

4. When predFlagLX is equal to 1, the derivation process for luma motion vector prediction in subclause 8.4.1.3 is invoked with mbPartIdx, subMbPartIdx, refIdxLX, and currSubMbType as the inputs and the output being mvLX. The luma motion vectors are derived by

$$\text{mvLX}[0] = \text{mvpLX}[0] + \text{mvd_lX}[\text{mbPartIdx}][\text{subMbPartIdx}][0] \quad (8-168)$$

$$\text{mvLX}[1] = \text{mvpLX}[1] + \text{mvd_lX}[\text{mbPartIdx}][\text{subMbPartIdx}][1] \quad (8-169)$$

For the derivation of the variables for the chroma motion vectors, the following applies. When predFlagLX (with X being either 0 or 1) is equal to 1, the derivation process for chroma motion vectors in subclause 8.4.1.4 is invoked with mvLX and refIdxLX as input and the output being mvCLX.

8.4.1.1 Derivation process for luma motion vectors for skipped macroblocks in P and SP slices

This process is invoked when mb_type is equal to P_Skip.

Outputs of this process are the motion vector mvL0 and the reference index refIdxL0.

The reference index refIdxL0 for a skipped macroblock is derived as follows.

$$\text{refIdxL0} = 0. \quad (8-170)$$

For the derivation of the motion vector mvL0 of a P_Skip macroblock type, the following applies.

- The process specified in subclause 8.4.1.3.2 is invoked with mbPartIdx set equal to 0, subMbPartIdx set equal to 0, currSubMbType set equal to "na", and listSuffixFlag set equal to 0 as input and the output is assigned to mbAddrA, mbAddrB, mvL0A, mvL0B, refIdxL0A, and refIdxL0B.
- The variable mvL0 is specified as follows.
 - If any of the following conditions are true, both components of the motion vector mvL0 are set equal to 0.
 - mbAddrA is not available
 - mbAddrB is not available
 - refIdxL0A is equal to 0 and both components of mvL0A are equal to 0
 - refIdxL0B is equal to 0 and both components of mvL0B are equal to 0

- Otherwise, the derivation process for luma motion vector prediction as specified in subclause 8.4.1.3 is invoked with `mbPartIdx = 0`, `subMbPartIdx = 0`, `refIdxL0`, and `currSubMbType = "na"` as inputs and the output is assigned to `mvL0`.

NOTE – The output is directly assigned to `mvL0`, since the predictor is equal to the actual motion vector.

8.4.1.2 Derivation process for luma motion vectors for B_Skip, B_Direct_16x16, and B_Direct_8x8

This process is invoked when `mb_type` is equal to `B_Skip` or `B_Direct_16x16`, or `sub_mb_type[mbPartIdx]` is equal to `B_Direct_8x8`.

Inputs to this process are `mbPartIdx` and `subMbPartIdx`.

Outputs of this process are the reference indices `refIdxL0`, `refIdxL1`, the motion vectors `mvL0` and `mvL1`, the sub-partition motion vector count `subMvCnt`, and the prediction list utilization flags, `predFlagL0` and `predFlagL1`.

The derivation process depends on the value of `direct_spatial_mv_pred_flag`, which is present in the bitstream in the slice header syntax as specified in subclause 7.3.3, and is specified as follows.

- If `direct_spatial_mv_pred_flag` is equal to 1, the mode in which the outputs of this process are derived is referred to as spatial direct prediction mode.
- Otherwise (`direct_spatial_mv_pred_flag` is equal to 0), mode in which the outputs of this process are derived is referred to as temporal direct prediction mode.

Both spatial and temporal direct prediction mode use the co-located motion vectors and reference indices as specified in subclause 8.4.1.2.1.

The motion vectors and reference indices are derived as follows.

- If spatial direct prediction mode is used, the direct motion vector and reference index prediction mode specified in subclause 8.4.1.2.2 is used, with `subMvCnt` being an output.
- Otherwise (temporal direct prediction mode is used), the direct motion vector and reference index prediction mode specified in subclause 8.4.1.2.3 is used and the variable `subMvCnt` is derived as follows.
 - If `subMbPartIdx` is equal to 0, `subMvCnt` is set equal to 2.
 - Otherwise (`subMbPartIdx` is not equal to 0), `subMvCnt` is set equal to 0.

8.4.1.2.1 Derivation process for the co-located 4x4 sub-macroblock partitions

Inputs to this process are `mbPartIdx` and `subMbPartIdx`.

Outputs of this process are the picture `colPic`, the co-located macroblock `mbAddrCol`, the motion vector `mvCol`, the reference index `refIdxCol`, and the variable `vertMvScale` (which can be `One_To_One`, `Frm_To_Fld` or `Fld_To_Frm`).

When `RefPicList1[0]` is a frame or a complementary field pair, let `firstRefPicL1Top` and `firstRefPicL1Bottom` be the top and bottom fields of `RefPicList1[0]`, respectively, and let the following variables be specified as

$$\text{topAbsDiffPOC} = \text{Abs}(\text{DiffPicOrderCnt}(\text{firstRefPicL1Top}, \text{CurrPic})) \quad (8-171)$$

$$\text{bottomAbsDiffPOC} = \text{Abs}(\text{DiffPicOrderCnt}(\text{firstRefPicL1Bottom}, \text{CurrPic})) \quad (8-172)$$

The variable colPic specifies the picture that contains the co-located macroblock as specified in Table 8-6.

Table 8-6 – Specification of the variable colPic

field_pic_flag	RefPicList1[0] is ...	mb_field_decoding_flag	additional condition	colPic
1	a field of a decoded frame			the frame containing RefPicList1[0]
	a decoded field			RefPicList1[0]
0	a decoded frame			RefPicList1[0]
	a complementary field pair	0	topAbsDiffPOC < bottomAbsDiffPOC	firstRefPicL1Top
			topAbsDiffPOC >= bottomAbsDiffPOC	firstRefPicL1Bottom
		1	(CurrMbAddr & 1) == 0	firstRefPicL1Top
			(CurrMbAddr & 1) != 0	firstRefPicL1Bottom

When direct_8x8_inference_flag is equal to 1, subMbPartIdx is set as follows.

$$\text{subMbPartIdx} = \text{mbPartIdx} \quad (8-173)$$

Let PicCodingStruct(X) be a function with the argument X being either CurrPic or colPic. It is specified in Table 8-7.

Table 8-7 – Specification of PicCodingStruct(X)

X is coded with field_pic_flag equal to ...	mb_adaptive_frame_field_flag	PicCodingStruct(X)
1		FLD
0	0	FRM
0	1	AFRM

With luma4x4BlkIdx = mbPartIdx * 4 + subMbPartIdx, the inverse 4x4 luma block scanning process as specified in subclause 6.4.3 is invoked with luma4x4BlkIdx as the input and (x, y) assigned to (xCol, yCol) as the output.

Table 8-8 specifies the co-located macroblock address mbAddrCol, yM, and the variable vertMvScale in two steps:

1. Specification of a macroblock address mbAddrX depending on PicCodingStruct(CurrPic), and PicCodingStruct(colPic).

NOTE – It is not possible for CurrPic and colPic picture coding types to be either (FRM, AFRM) or (AFRM, FRM) because these picture coding types must be separated by an IDR picture.

2. Specification of mbAddrCol, yM, and vertMvScale depending on mb_field_decoding_flag and the variable fieldDecodingFlagX, which is derived as follows.
 - If the macroblock mbAddrX in the picture colPic is a field macroblock, fieldDecodingFlagX is set equal to 1
 - Otherwise (the macroblock mbAddrX in the picture colPic is a frame macroblock), fieldDecodingFlagX is set equal to 0.

Unspecified values in Table 8-8 indicate that the value of the corresponding variable is not relevant for the current table row.

mbAddrCol is set equal to CurrMbAddr or to one of the following values.

$$\text{mbAddrCol1} = 2 * \text{PicWidthInMbs} * (\text{CurrMbAddr} / \text{PicWidthInMbs}) + (\text{CurrMbAddr} \% \text{PicWidthInMbs}) + \text{PicWidthInMbs} * (\text{yCol} / 8) \quad (8-174)$$

$$\text{mbAddrCol2} = 2 * \text{CurrMbAddr} + (\text{yCol} / 8) \quad (8-175)$$

$$\text{mbAddrCol3} = 2 * \text{CurrMbAddr} + \text{bottom_field_flag} \quad (8-176)$$

$$\text{mbAddrCol4} = \text{PicWidthInMbs} * (\text{CurrMbAddr} / (2 * \text{PicWidthInMbs})) + (\text{CurrMbAddr} \% \text{PicWidthInMbs}) \quad (8-177)$$

$$\text{mbAddrCol5} = \text{CurrMbAddr} / 2 \quad (8-178)$$

$$\text{mbAddrCol6} = 2 * (\text{CurrMbAddr} / 2) + ((\text{topAbsDiffPOC} < \text{bottomAbsDiffPOC}) ? 0 : 1) \quad (8-179)$$

$$\text{mbAddrCol7} = 2 * (\text{CurrMbAddr} / 2) + (\text{yCol} / 8) \quad (8-180)$$

Table 8-8 – Specification of mbAddrCol, yM, and vertMvScale

PicCodingStruct(CurrPic)	PicCodingStruct(colPic)	mbAddrX	mb_field_decoding_flag	fieldDecodingFlagX	mbAddrCol	yM	vertMvScale
FLD	FLD				CurrMbAddr	yCol	One_To_One
	FRM				mbAddrCol1	(2 * yCol) % 16	Frm_To_Fld
	AFRM	2*CurrMbAddr	0		mbAddrCol2	(2 * yCol) % 16	Frm_To_Fld
			1		mbAddrCol3	yCol	One_To_One
FRM	FLD				mbAddrCol4	8 * ((CurrMbAddr / PicWidthInMbs) % 2) + 4 * (yCol / 8)	Fld_To_Frm
	FRM				CurrMbAddr	yCol	One_To_One
AFRM	FLD		0		mbAddrCol5	8 * (CurrMbAddr % 2) + 4 * (yCol / 8)	Fld_To_Frm
			1		mbAddrCol5	yCol	One_To_One
	AFRM	CurrMbAddr	0	0	CurrMbAddr	yCol	One_To_One
			1		mbAddrCol6	8 * (CurrMbAddr % 2) + 4 * (yCol / 8)	Fld_To_Frm
		CurrMbAddr	0		mbAddrCol7	(2 * yCol) % 16	Frm_To_Fld
			1		CurrMbAddr	yCol	One_To_One

Let mbPartIdxCol be the macroblock partition index of the co-located partition and subMbPartIdxCol the sub-macroblock partition index of the co-located sub-macroblock partition. The partition in the macroblock mbAddrCol inside the picture colPic covering the sample (xCol, yM) is assigned to mbPartIdxCol and the sub-macroblock partition inside the partition mbPartIdxCol covering the sample (xCol, yM) in the macroblock mbAddrCol inside the picture colPic is assigned to subMbPartIdxCol.

The prediction utilization flags `predFlagL0Col` and `predFlagL1Col` are set equal to `PredFlagL0[mbPartIdxCol]` and `PredFlagL1[mbPartIdxCol]`, respectively, which are the prediction utilization flags that have been assigned to the macroblock partition `mbAddrCol\mbPartIdxCol` inside the picture `colPic`.

The motion vector `mvCol` and the reference index `refIdxCol` are derived as follows.

- If the macroblock `mbAddrCol` is coded in Intra macroblock prediction mode or both prediction utilization flags, `predFlagL0Col` and `predFlagL1Col` are equal to 0, both components of `mvCol` are set equal to 0 and `refIdxCol` is set equal to -1.
- Otherwise, the following applies.
 - If `predFlagL0Col` is equal to 1, the motion vector `mvCol` and the reference index `refIdxCol` are set equal to `MvL0[mbPartIdxCol][subMbPartIdxCol]` and `RefIdxL0[mbPartIdxCol]`, respectively, which are the motion vector `mvL0` and the reference index `refIdxL0` that have been assigned to the (sub-)macroblock partition `mbAddrCol\mbPartIdxCol\subMbPartIdxCol` inside the picture `colPic`.
 - Otherwise (`predFlagL0Col` is equal to 0 and `predFlagL1Col` is equal to 1), the motion vector `mvCol` and the reference index `refIdxCol` are set equal to `MvL1[mbPartIdxCol][subMbPartIdxCol]` and `RefIdxL1[mbPartIdxCol]`, respectively, which are the motion vector `mvL1` and the reference index `refIdxL1` that have been assigned to the (sub-)macroblock partition `mbAddrCol\mbPartIdxCol\subMbPartIdxCol` inside the picture `colPic`.

8.4.1.2.2 Derivation process for spatial direct luma motion vector and reference index prediction mode

This process is invoked when `direct_spatial_mv_pred_flag` is equal to 1 and any of the following conditions is true.

- `mb_type` is equal to `B_Skip`
- `mb_type` is equal to `B_Direct_16x16`
- `sub_mb_type[mbPartIdx]` is equal to `B_Direct_8x8`.

Inputs to this process are `mbPartIdx`, `subMbPartIdx`.

Outputs of this process are the reference indices `refIdxL0`, `refIdxL1`, the motion vectors `mvL0` and `mvL1`, the sub-partition motion vector count `subMvCnt`, and the prediction list utilization flags, `predFlagL0` and `predFlagL1`.

The reference indices `refIdxL0` and `refIdxL1` and the variable `directZeroPredictionFlag` are derived by applying the following ordered steps.

1. Let the variable `currSubMbType` be set equal to `sub_mb_type[mbPartIdx]`.
2. The process specified in subclause 8.4.1.3.2 is invoked with `mbPartIdx = 0`, `subMbPartIdx = 0`, `currSubMbType`, and `listSuffixFlag = 0` as inputs and the output is assigned to the motion vectors `mvL0N` and the reference indices `refIdxL0N` with `N` being replaced by `A`, `B`, or `C`.
3. The process specified in subclause 8.4.1.3.2 is invoked with `mbPartIdx = 0`, `subMbPartIdx = 0`, `currSubMbType`, and `listSuffixFlag = 1` as inputs and the output is assigned to the motion vectors `mvL1N` and the reference indices `refIdxL1N` with `N` being replaced by `A`, `B`, or `C`.

NOTE 1 – The motion vectors `mvL0N`, `mvL1N` and the reference indices `refIdxL0N`, `refIdxL1N` are identical for all 4x4 sub-macroblock partitions of a macroblock.

4. The reference indices `refIdxL0`, `refIdxL1`, and `directZeroPredictionFlag` are derived by

$$\text{refIdxL0} = \text{MinPositive}(\text{refIdxL0A}, \text{MinPositive}(\text{refIdxL0B}, \text{refIdxL0C})) \quad (8-181)$$

$$\text{refIdxL1} = \text{MinPositive}(\text{refIdxL1A}, \text{MinPositive}(\text{refIdxL1B}, \text{refIdxL1C})) \quad (8-182)$$

$$\text{directZeroPredictionFlag} = 0 \quad (8-183)$$

where

$$\text{MinPositive}(x, y) = \begin{cases} \text{Min}(x, y) & \text{if } x \geq 0 \text{ and } y \geq 0 \\ \text{Max}(x, y) & \text{otherwise} \end{cases} \quad (8-184)$$

5. When both reference indices refIdxL0 and refIdxL1 are less than 0,

$$\text{refIdxL0} = 0 \quad (8-185)$$

$$\text{refIdxL1} = 0 \quad (8-186)$$

$$\text{directZeroPredictionFlag} = 1 \quad (8-187)$$

The process specified in subclause 8.4.1.2.1 is invoked with mbPartIdx, subMbPartIdx given as input and the output is assigned to refIdxCol and mvCol.

The variable colZeroFlag is derived as follows.

- If all of the following conditions are true, colZeroFlag is set equal to 1.
 - RefPicList1[0] is currently marked as "used for short-term reference".
 - refIdxCol is equal to 0
 - both motion vector components mvCol[0] and mvCol[1] lie in the range of -1 to 1 in units specified as follows.
 - If the co-located macroblock is a frame macroblock, the units of mvCol[0] and mvCol[1] are units of quarter luma frame samples.
 - Otherwise (the co-located macroblock is a field macroblock), the units of mvCol[0] and mvCol[1] are units of quarter luma field samples.

NOTE 2 – For purposes of determining the condition above, the value mvCol[1] is not scaled to use the units of a motion vector for the current macroblock in cases when the current macroblock is a frame macroblock and the co-located macroblock is a field macroblock or when the current macroblock is a field macroblock and the co-located macroblock is a frame macroblock. This aspect differs from the use of mvCol[1] in the temporal direct mode as specified in subclause 8.4.1.2.3, which applies scaling to the motion vector of the co-located macroblock to use the same units as the units of a motion vector for the current macroblock, using Equation 8-190 or Equation 8-191 in these cases.

- Otherwise, colZeroFlag is set equal to 0.

The motion vectors mvLX (with X being 0 or 1) are derived as follows.

- If any of the following conditions is true, both components of the motion vector mvLX are set equal to 0.
 - directZeroPredictionFlag is equal to 1
 - refIdxLX is less than 0
 - refIdxLX is equal to 0 and colZeroFlag is equal to 1
- Otherwise, the process specified in subclause 8.4.1.3 is invoked with mbPartIdx = 0, subMbPartIdx = 0, refIdxLX, and currSubMbType as inputs and the output is assigned to mvLX.

NOTE 3 – The motion vector mvLX returned from subclause 8.4.1.3 is identical for all 4x4 sub-macroblock partitions of a macroblock for which the process is invoked.

The prediction utilization flags predFlagL0 and predFlagL1 are derived as specified using Table 8-9.

Table 8-9 – Assignment of prediction utilization flags

refIdxL0	refIdxL1	predFlagL0	predFlagL1
≥ 0	≥ 0	1	1
≥ 0	< 0	1	0
< 0	≥ 0	0	1

The variable subMvCnt is derived as follows.

- If subMbPartIdx is not equal to 0 or direct_8x8_inference_flag is equal to 0, subMvCnt is set equal to 0.
- Otherwise (subMbPartIdx is equal to 0 and direct_8x8_inference_flag is equal to 1), subMvCnt is set equal to predFlagL0 + predFlagL1.

8.4.1.2.3 Derivation process for temporal direct luma motion vector and reference index prediction mode

This process is invoked when `direct_spatial_mv_pred_flag` is equal to 0 and any of the following conditions is true.

- `mb_type` is equal to `B_Skip`
- `mb_type` is equal to `B_Direct_16x16`
- `sub_mb_type[mbPartIdx]` is equal to `B_Direct_8x8`.

Inputs to this process are `mbPartIdx` and `subMbPartIdx`.

Outputs of this process are the motion vectors `mvL0` and `mvL1`, the reference indices `refIdxL0` and `refIdxL1`, and the prediction list utilization flags, `predFlagL0` and `predFlagL1`.

The process specified in subclause 8.4.1.2.1 is invoked with `mbPartIdx`, `subMbPartIdx` given as input and the output is assigned to `colPic`, `mbAddrCol`, `mvCol`, `refIdxCol`, and `vertMvScale`.

The reference indices `refIdxL0` and `refIdxL1` are derived as follows.

$$\text{refIdxL0} = ((\text{refIdxCol} < 0) ? 0 : \text{MapColToList0}(\text{refIdxCol})) \quad (8-188)$$

$$\text{refIdxL1} = 0 \quad (8-189)$$

NOTE 1 – If the current macroblock is a field macroblock, `refIdxL0` and `refIdxL1` index a list of fields; otherwise (the current macroblock is a frame macroblock), `refIdxL0` and `refIdxL1` index a list of frames or complementary reference field pairs.

Let `refPicCol` be a frame, a field, or a complementary field pair that was referred by the reference index `refIdxCol` when decoding the co-located macroblock `mbAddrCol` inside the picture `colPic`. The function `MapColToList0(refIdxCol)` is specified as follows.

- If `vertMvScale` is equal to `One_To_One`, the following applies.
 - If `field_pic_flag` is equal to 0 and the current macroblock is a field macroblock, the following applies.
 - Let `refIdxL0Frm` be the lowest valued reference index in the current reference picture list `RefPicList0` that references the frame or complementary field pair that contains the field `refPicCol`. `RefPicList0` shall contain a frame or complementary field pair that contains the field `refPicCol`. The return value of `MapColToList0()` is specified as follows.
 - If the field referred to by `refIdxCol` has the same parity as the current macroblock, `MapColToList0(refIdxCol)` returns the reference index $(\text{refIdxL0Frm} \ll 1)$.
 - Otherwise (the field referred by `refIdxCol` has the opposite parity of the current macroblock), `MapColToList0(refIdxCol)` returns the reference index $((\text{refIdxL0Frm} \ll 1) + 1)$.
 - Otherwise (`field_pic_flag` is equal to 1 or the current macroblock is a frame macroblock), `MapColToList0(refIdxCol)` returns the lowest valued reference index `refIdxL0` in the current reference picture list `RefPicList0` that references `refPicCol`. `RefPicList0` shall contain `refPicCol`.
 - Otherwise, if `vertMvScale` is equal to `Frm_To_Fld`, the following applies.
 - If `field_pic_flag` is equal to 0, let `refIdxL0Frm` be the lowest valued reference index in the current reference picture list `RefPicList0` that references `refPicCol`. `MapColToList0(refIdxCol)` returns the reference index $(\text{refIdxL0Frm} \ll 1)$. `RefPicList0` shall contain `refPicCol`.
 - Otherwise (`field_pic_flag` is equal to 1), `MapColToList0(refIdxCol)` returns the lowest valued reference index `refIdxL0` in the current reference picture list `RefPicList0` that references the field of `refPicCol` with the same parity as the current picture `CurrPic`. `RefPicList0` shall contain the field of `refPicCol` with the same parity as the current picture `CurrPic`.
 - Otherwise (`vertMvScale` is equal to `Fld_To_Frm`), `MapColToList0(refIdxCol)` returns the lowest valued reference index `refIdxL0` in the current reference picture list `RefPicList0` that references the frame or complementary field pair that contains `refPicCol`. `RefPicList0` shall contain a frame or complementary field pair that contains the field `refPicCol`.

NOTE 2 – A decoded reference picture that was marked as "used for short-term reference" when it was referenced in the decoding process of the picture containing the co-located macroblock may have been modified to be marked as "used for long-term reference" before being used for reference for inter prediction using the direct prediction mode for the current macroblock.

Depending on the value of `vertMvScale` the vertical component of `mvCol` is modified as follows.

- If `vertMvScale` is equal to `Frm_To_Fld`

$$\text{mvCol}[1] = \text{mvCol}[1] / 2 \quad (8-190)$$

- Otherwise, if `vertMvScale` is equal to `Fld_To_Frm`

$$\text{mvCol}[1] = \text{mvCol}[1] * 2 \quad (8-191)$$

- Otherwise (`vertMvScale` is equal to `One_To_One`), `mvCol[1]` remains unchanged.

The variables `currPicOrField`, `pic0`, and `pic1`, are derived as follows.

- If `field_pic_flag` is equal to 0 and the current macroblock is a field macroblock, the following applies.
 - `currPicOrField` is the field of the current picture `CurrPic` that has the same parity as the current macroblock.
 - `pic1` is the field of `RefPicList1[0]` that has the same parity as the current macroblock.
 - The variable `pic0` is derived as follows.
 - If `refIdxL0 % 2` is equal to 0, `pic0` is the field of `RefPicList0[refIdxL0 / 2]` that has the same parity as the current macroblock.
 - Otherwise (`refIdxL0 % 2` is not equal to 0), `pic0` is the field of `RefPicList0[refIdxL0 / 2]` that has the opposite parity of the current macroblock.
- Otherwise (`field_pic_flag` is equal to 1 or the current macroblock is a frame macroblock), `currPicOrField` is the current picture `CurrPic`, `pic1` is the decoded reference picture `RefPicList1[0]`, and `pic0` is the decoded reference picture `RefPicList0[refIdxL0]`.

The two motion vectors `mvL0` and `mvL1` for each 4x4 sub-macroblock partition of the current macroblock are derived as follows:

NOTE 3 – It is often the case that many of the 4x4 sub-macroblock partitions share the same motion vectors and reference pictures. In these cases, temporal direct mode motion compensation can calculate the inter prediction sample values in larger units than 4x4 luma sample blocks. For example, when `direct_8x8_inference_flag` is equal to 1, at least each 8x8 luma sample quadrant of the macroblock shares the same motion vectors and reference pictures.

- If the reference index `refIdxL0` refers to a long-term reference picture, or `DiffPicOrderCnt(pic1, pic0)` is equal to 0, the motion vectors `mvL0`, `mvL1` for the direct mode partition are derived by

$$\text{mvL0} = \text{mvCol} \quad (8-192)$$

$$\text{mvL1} = 0 \quad (8-193)$$

- Otherwise, the motion vectors `mvL0`, `mvL1` are derived as scaled versions of the motion vector `mvCol` of the co-located sub-macroblock partition as specified below (see Figure 8-2)

$$\text{tx} = (16384 + \text{Abs}(\text{td} / 2)) / \text{td} \quad (8-194)$$

$$\text{DistScaleFactor} = \text{Clip3}(-1024, 1023, (\text{tb} * \text{tx} + 32) \gg 6) \quad (8-195)$$

$$\text{mvL0} = (\text{DistScaleFactor} * \text{mvCol} + 128) \gg 8 \quad (8-196)$$

$$\text{mvL1} = \text{mvL0} - \text{mvCol} \quad (8-197)$$

where `tb` and `td` are derived as follows.

$$\text{tb} = \text{Clip3}(-128, 127, \text{DiffPicOrderCnt}(\text{currPicOrField}, \text{pic0})) \quad (8-198)$$

$$\text{td} = \text{Clip3}(-128, 127, \text{DiffPicOrderCnt}(\text{pic1}, \text{pic0})) \quad (8-199)$$

NOTE 4 – mvL0 and mvL1 cannot exceed the ranges specified in Annex A.

The prediction utilization flags predFlagL0 and predFlagL1 are both set equal to 1.

Figure 8-2 illustrates the temporal direct-mode motion vector inference when the current picture is temporally between the reference picture from reference picture list 0 and the reference picture from reference picture list 1.

Figure 8-2 – Example for temporal direct-mode motion vector inference (informative)

8.4.1.3 Derivation process for luma motion vector prediction

Inputs to this process are

- the macroblock partition index mbPartIdx,
- the sub-macroblock partition index subMbPartIdx,
- the reference index of the current partition refIdxLX (with X being 0 or 1),
- the variable currSubMbType.

Output of this process is the prediction mvpLX of the motion vector mvLX (with X being 0 or 1).

The derivation process for the neighbouring blocks for motion data in subclause 8.4.1.3.2 is invoked with mbPartIdx, subMbPartIdx, currSubMbType, and listSuffixFlag = X (with X being 0 or 1 for refIdxLX being refIdxL0 or refIdxL1, respectively) as the input and with mbAddrN\mbPartIdxN\subMbPartIdxN, reference indices refIdxLXN and the motion vectors mvLXN with N being replaced by A, B, or C as the output.

The derivation process for median luma motion vector prediction in subclause 8.4.1.3.1 is invoked with mbAddrN\mbPartIdxN\subMbPartIdxN, mvLXN, refIdxLXN with N being replaced by A, B, or C and refIdxLX as the input and mvpLX as the output, unless one of the following is true.

- MbPartWidth(mb_type) is equal to 16, MbPartHeight(mb_type) is equal to 8, mbPartIdx is equal to 0, and refIdxLXB is equal to refIdxLX,

$$\text{mvpLX} = \text{mvLXB} \quad (8-200)$$

- MbPartWidth(mb_type) is equal to 16, MbPartHeight(mb_type) is equal to 8, mbPartIdx is equal to 1, and refIdxLXA is equal to refIdxLX,

$$\text{mvpLX} = \text{mvLXA} \quad (8-201)$$

- MbPartWidth(mb_type) is equal to 8, MbPartHeight(mb_type) is equal to 16, mbPartIdx is equal to 0, and refIdxLXA is equal to refIdxLX,

$$\text{mvpLX} = \text{mvLXA} \quad (8-202)$$

- MbPartWidth(mb_type) is equal to 8, MbPartHeight(mb_type) is equal to 16, mbPartIdx is equal to 1, and refIdxLXC is equal to refIdxLX,

$$\text{mvpLX} = \text{mvLXC} \quad (8-203)$$

Figure 8-3 illustrates the non-median prediction as described above.

Figure 8-3 – Directional segmentation prediction (informative)

8.4.1.3.1 Derivation process for median luma motion vector prediction

Inputs to this process are

- the neighbouring partitions mbAddrN\mbPartIdxN\subMbPartIdxN (with N being replaced by A, B, or C),
- the motion vectors mvLXN (with N being replaced by A, B, or C) of the neighbouring partitions,
- the reference indices refIdxLXN (with N being replaced by A, B, or C) of the neighbouring partitions, and
- the reference index refIdxLX of the current partition.

Output of this process is the motion vector prediction mvpLX.

The variable mvpLX is derived as follows:

- When both partitions mbAddrB\mbPartIdxB\subMbPartIdxB and mbAddrC\mbPartIdxC\subMbPartIdxC are not available and mbAddrA\mbPartIdxA\subMbPartIdxA is available,

$$\text{mvLXB} = \text{mvLXA} \quad (8-204)$$

$$\text{mvLXC} = \text{mvLXA} \quad (8-205)$$

$$\text{refIdxLXB} = \text{refIdxLXA} \quad (8-206)$$

$$\text{refIdxLXC} = \text{refIdxLXA} \quad (8-207)$$

- Depending on reference indices refIdxLXA, refIdxLXB, or refIdxLXC, the following applies.
 - If one and only one of the reference indices refIdxLXA, refIdxLXB, or refIdxLXC is equal to the reference index refIdxLX of the current partition, the following applies. Let refIdxLXN be the reference index that is equal to refIdxLX, the motion vector mvLXN is assigned to the motion vector prediction mvpLX:

$$\text{mvpLX} = \text{mvLXN} \quad (8-208)$$

- Otherwise, each component of the motion vector prediction mvpLX is given by the median of the corresponding vector components of the motion vector mvLXA, mvLXB, and mvLXC:

$$\text{mvpLX}[0] = \text{Median}(\text{mvLXA}[0], \text{mvLXB}[0], \text{mvLXC}[0]) \quad (8-209)$$

$$\text{mvLX}[1] = \text{Median}(\text{mvLXA}[1], \text{mvLXB}[1], \text{mvLXC}[1]) \quad (8-210)$$

8.4.1.3.2 Derivation process for motion data of neighbouring partitions

Inputs to this process are

- the macroblock partition index mbPartIdx,
- the sub-macroblock partition index subMbPartIdx,
- the current sub-macroblock type currSubMbType,
- the list suffix flag listSuffixFlag

Outputs of this process are (with N being replaced by A, B, or C)

- mbAddrN\mbPartIdxN\subMbPartIdxN specifying neighbouring partitions,
- the motion vectors mvLXN of the neighbouring partitions, and
- the reference indices refIdxLXN of the neighbouring partitions.

Variable names that include the string "LX" are interpreted with the X being equal to listSuffixFlag.

The partitions mbAddrN\mbPartIdxN\subMbPartIdxN with N being either A, B, or C are derived in the following ordered steps.

1. Let mbAddrD\mbPartIdxD\subMbPartIdxD be variables specifying an additional neighbouring partition.
2. The process in subclause 6.4.8.5 is invoked with mbPartIdx, currSubMbType, and subMbPartIdx as input and the output is assigned to mbAddrN\mbPartIdxN\subMbPartIdxN with N being replaced by A, B, C, or D.
3. When the partition mbAddrC\mbPartIdxC\subMbPartIdxC is not available, the following applies

$$\text{mbAddrC} = \text{mbAddrD} \quad (8-211)$$

$$\text{mbPartIdxC} = \text{mbPartIdxD} \quad (8-212)$$

$$\text{subMbPartIdxC} = \text{subMbPartIdxD} \quad (8-213)$$

The motion vectors mvLXN and reference indices refIdxLXN (with N being A, B, or C) are derived as follows.

- If the macroblock partition or sub-macroblock partition mbAddrN\mbPartIdxN\subMbPartIdxN is not available or mbAddrN is coded in Intra prediction mode or predFlagLX of mbAddrN\mbPartIdxN\subMbPartIdxN is equal to 0, both components of mvLXN are set equal to 0 and refIdxLXN is set equal to -1.
- Otherwise, the following applies.
 - The motion vector mvLXN and reference index refIdxLXN are set equal to $\text{MvLX}[\text{mbPartIdxN}][\text{subMbPartIdxN}]$ and $\text{RefIdxLX}[\text{mbPartIdxN}]$, respectively, which are the motion vector mvLX and reference index refIdxLX that have been assigned to the (sub-)macroblock partition mbAddrN\mbPartIdxN\subMbPartIdxN.
 - The variables mvLXN[1] and refIdxLXN are further processed as follows.

- If the current macroblock is a field macroblock and the macroblock mbAddrN is a frame macroblock

$$\text{mvLXN}[1] = \text{mvLXN}[1] / 2 \quad (8-214)$$

$$\text{refIdxLXN} = \text{refIdxLXN} * 2 \quad (8-215)$$

- Otherwise, if the current macroblock is a frame macroblock and the macroblock mbAddrN is a field macroblock

$$\text{mvLXN}[1] = \text{mvLXN}[1] * 2 \quad (8-216)$$

$$\text{refIdxLXN} = \text{refIdxLXN} / 2 \quad (8-217)$$

- Otherwise, the vertical motion vector component $\text{mvLXN}[1]$ and the reference index refIdxLXN remain unchanged.

8.4.1.4 Derivation process for chroma motion vectors

This process is only invoked when chroma_format_idc is not equal to 0 (monochrome).

Inputs to this process are a luma motion vector mvLX and a reference index refIdxLX .

Output of this process is a chroma motion vector mvCLX .

A chroma motion vector is derived from the corresponding luma motion vector.

The precision of the chroma motion vector components is $1 \div (4 * \text{SubWidthC})$ horizontally and $1 \div (4 * \text{SubHeightC})$ vertically.

NOTE – For example, when using the 4:2:0 chroma format, since the units of luma motion vectors are one-quarter luma sample units and chroma has half horizontal and vertical resolution compared to luma, the units of chroma motion vectors are one-eighth chroma sample units, i.e., a value of 1 for the chroma motion vector refers to a one-eighth chroma sample displacement. For example, when the luma vector applies to 8x16 luma samples, the corresponding chroma vector in 4:2:0 chroma format applies to 4x8 chroma samples and when the luma vector applies to 4x4 luma samples, the corresponding chroma vector in 4:2:0 chroma format applies to 2x2 chroma samples.

For the derivation of the motion vector mvCLX , the following applies.

- If chroma_format_idc is not equal to 1 or the current macroblock is a frame macroblock, the horizontal and vertical components of the chroma motion vector mvCLX are derived as

$$\text{mvCLX}[0] = \text{mvLX}[0] \quad (8-218)$$

$$\text{mvCLX}[1] = \text{mvLX}[1] \quad (8-219)$$

- Otherwise (chroma_format_idc is equal to 1 and the current macroblock is a field macroblock), only the horizontal component of the chroma motion vector $\text{mvCLX}[0]$ is derived using Equation 8-218. The vertical component of the chroma motion vector $\text{mvCLX}[1]$ is dependent on the parity of the current field or the current macroblock and the reference picture, which is referred by the reference index refIdxLX . $\text{mvCLX}[1]$ is derived from $\text{mvLX}[1]$ according to Table 8-10.

Table 8-10 – Derivation of the vertical component of the chroma vector in field coding mode

Parity conditions		$\text{mvCLX}[1]$
Reference picture (refIdxLX)	Current field (picture/macroblock)	
Top field	Bottom field	$\text{mvLX}[1] + 2$
Bottom field	Top field	$\text{mvLX}[1] - 2$
Otherwise		$\text{mvLX}[1]$

8.4.2 Decoding process for Inter prediction samples

Inputs to this process are

- a macroblock partition mbPartIdx ,
- a sub-macroblock partition subMbPartIdx .
- variables specifying partition width and height for luma and chroma (if available), partWidth , partHeight , partWidthC (if available) and partHeightC (if available)
- luma motion vectors mvL0 and mvL1 and when chroma_format_idc is not equal to 0 (monochrome) chroma motion vectors mvCL0 and mvCL1
- reference indices refIdxL0 and refIdxL1

- prediction list utilization flags, predFlagL0 and predFlagL1

Outputs of this process are

- the Inter prediction samples predPart, which are a (partWidth)x(partHeight) array predPart_L of prediction luma samples, and when chroma_format_idc is not equal to 0 (monochrome) two (partWidthC)x(partHeightC) arrays predPart_{Cb}, predPart_{Cr} of prediction chroma samples, one for each of the chroma components Cb and Cr.

Let predPartL0_L and predPartL1_L be (partWidth)x(partHeight) arrays of predicted luma sample values and when chroma_format_idc is not equal to 0 (monochrome) predPartL0_{Cb}, predPartL1_{Cb}, predPartL0_{Cr}, and predPartL1_{Cr} be (partWidthC)x(partHeightC) arrays of predicted chroma sample values.

For LX being replaced by either L0 or L1 in the variables predFlagLX, RefPicListX, refIdxLX, refPicLX, predPartLX, the following is specified.

When predFlagLX is equal to 1, the following applies.

- The reference picture consisting of an ordered two-dimensional array refPicLX_L of luma samples and when chroma_format_idc is not equal to 0 (monochrome) two ordered two-dimensional arrays refPicLX_{Cb} and refPicLX_{Cr} of chroma samples is derived by invoking the process specified in subclause 8.4.2.1 with refIdxLX and RefPicListX given as input.
- The array predPartLX_L and when chroma_format_idc is not equal to 0 (monochrome) the arrays predPartLX_{Cb} and predPartLX_{Cr} are derived by invoking the process specified in subclause 8.4.2.2 with the current partition specified by mbPartIdx\subMbPartIdx, the motion vectors mvLX, mvCLX (if available), and the reference arrays with refPicLX_L, refPicLX_{Cb} (if available), and refPicLX_{Cr} (if available) given as input.

For C being replaced by L, Cb (if available), or Cr (if available), the array predPart_C of the prediction samples of component C is derived by invoking the process specified in subclause 8.4.2.3 with the current partition specified by mbPartIdx and subMbPartIdx and the array predPartL0_C and predPartL1_C as well as predFlagL0 and predFlagL1 given as input.

8.4.2.1 Reference picture selection process

Input to this process is a reference index refIdxLX.

Output of this process is a reference picture consisting of a two-dimensional array of luma samples refPicLX_L and two two-dimensional arrays of chroma samples refPicLX_{Cb} and refPicLX_{Cr}.

Depending on field_pic_flag, the reference picture list RefPicListX (which has been derived as specified in subclause 8.2.4) consists of the following.

- If field_pic_flag is equal to 1, each entry of RefPicListX is a reference field or a field of a reference frame.
- Otherwise (field_pic_flag is equal to 0), each entry of RefPicListX is a reference frame or a complementary reference field pair.

For the derivation of the reference picture, the following applies.

- If field_pic_flag is equal to 1, the reference field or field of a reference frame RefPicListX[refIdxLX] is the output. The output reference field or field of a reference frame consists of a (PicWidthInSamples_L)x(PicHeightInSamples_L) array of luma samples refPicLX_L and, when chroma_format_idc is not equal to 0 (monochrome), two (PicWidthInSamples_C)x(PicHeightInSamples_C) arrays of chroma samples refPicLX_{Cb} and refPicLX_{Cr}.
- Otherwise (field_pic_flag is equal to 0), the following applies.
 - If the current macroblock is a frame macroblock, the reference frame or complementary reference field pair RefPicListX[refIdxLX] is the output. The output reference frame or complementary reference field pair consists of a (PicWidthInSamples_L)x(PicHeightInSamples_L) array of luma samples refPicLX_L and, when chroma_format_idc is not equal to 0 (monochrome), two (PicWidthInSamples_C)x(PicHeightInSamples_C) arrays of chroma samples refPicLX_{Cb} and refPicLX_{Cr}.
 - Otherwise (the current macroblock is a field macroblock), the following applies.
 - Let refFrame be the reference frame or complementary reference field pair RefPicListX[refIdxLX / 2].
 - The field of refFrame is selected as follows.
 - If refIdxLX % 2 is equal to 0, the field of refFrame that has the same parity as the current macroblock is the output.

- Otherwise ($\text{refIdxLX} \% 2$ is equal to 1), the field of refFrame that has the opposite parity as the current macroblock is the output.
- The output reference field or field of a reference frame consists of a $(\text{PicWidthInSamples}_L) \times (\text{PicHeightInSamples}_L / 2)$ array of luma samples refPicLX_L and, when chroma_format_idc is not equal to 0 (monochrome), two $(\text{PicWidthInSamples}_C) \times (\text{PicHeightInSamples}_C / 2)$ arrays of chroma samples refPicLX_{Cb} and refPicLX_{Cr} .

The reference picture sample arrays refPicLX_L , refPicLX_{Cb} (if available), and refPicLX_{Cr} (if available) correspond to decoded sample arrays S_L , S_{Cb} (if available), S_{Cr} (if available) derived in subclause 8.7 for a previously-decoded reference field or reference frame or complementary reference field pair or field of a reference frame.

8.4.2.2 Fractional sample interpolation process

Inputs to this process are

- the current partition given by its partition index mbPartIdx and its sub-macroblock partition index subMbPartIdx ,
- the width and height partWidth , partHeight of this partition in luma-sample units,
- a luma motion vector mvLX given in quarter-luma-sample units,
- a chroma motion vector mvCLX given in eighth-chroma-sample units, and
- the selected reference picture sample arrays refPicLX_L , refPicLX_{Cb} , and refPicLX_{Cr}

Outputs of this process are

- a $(\text{partWidth}) \times (\text{partHeight})$ array predPartLX_L of prediction luma sample values and
- when chroma_format_idc is not equal to 0 (monochrome) two $(\text{partWidthC}) \times (\text{partHeightC})$ arrays predPartLX_{Cb} , and predPartLX_{Cr} of prediction chroma sample values.

Let (x_{A_L}, y_{A_L}) be the location given in full-sample units of the upper-left luma sample of the current partition given by $\text{mbPartIdx} \backslash \text{subMbPartIdx}$ relative to the upper-left luma sample location of the given two-dimensional array of luma samples.

Let (x_{Int_L}, y_{Int_L}) be a luma location given in full-sample units and (x_{Frac_L}, y_{Frac_L}) be an offset given in quarter-sample units. These variables are used only inside this subclause for specifying general fractional-sample locations inside the reference sample arrays refPicLX_L , refPicLX_{Cb} (if available), and refPicLX_{Cr} (if available).

For each luma sample location $(0 \leq x_L < \text{partWidth}, 0 \leq y_L < \text{partHeight})$ inside the prediction luma sample array predPartLX_L , the corresponding prediction luma sample value $\text{predPartLX}_L[x_L, y_L]$ is derived as follows:

- The variables x_{Int_L} , y_{Int_L} , x_{Frac_L} , and y_{Frac_L} are derived by

$$x_{Int_L} = x_{A_L} + (\text{mvLX}[0] \gg 2) + x_L \quad (8-220)$$

$$y_{Int_L} = y_{A_L} + (\text{mvLX}[1] \gg 2) + y_L \quad (8-221)$$

$$x_{Frac_L} = \text{mvLX}[0] \& 3 \quad (8-222)$$

$$y_{Frac_L} = \text{mvLX}[1] \& 3 \quad (8-223)$$

- The prediction luma sample value $\text{predPartLX}_L[x_L, y_L]$ is derived by invoking the process specified in subclause 8.4.2.2.1 with (x_{Int_L}, y_{Int_L}) , (x_{Frac_L}, y_{Frac_L}) and refPicLX_L given as input.

When chroma_format_idc is not equal to 0 (monochrome), the following applies.

Let (x_{Int_C}, y_{Int_C}) be a chroma location given in full-sample units and (x_{Frac_C}, y_{Frac_C}) be an offset given in one-eighth sample units. These variables are used only inside this subclause for specifying general fractional-sample locations inside the reference sample arrays refPicLX_{Cb} , and refPicLX_{Cr} .

For each chroma sample location $(0 \leq x_C < \text{partWidthC}, 0 \leq y_C < \text{partHeightC})$ inside the prediction chroma sample arrays predPartLX_{Cb} and predPartLX_{Cr} , the corresponding prediction chroma sample values $\text{predPartLX}_{Cb}[x_C, y_C]$ and $\text{predPartLX}_{Cr}[x_C, y_C]$ are derived as follows:

- Depending on chroma_format_idc , the variables x_{Int_C} , y_{Int_C} , x_{Frac_C} , and y_{Frac_C} are derived as follows.
 - If chroma_format_idc is equal to 1,

$$xInt_C = (xA_L / SubWidthC) + (mvCLX[0] >> 3) + x_C \quad (8-224)$$

$$yInt_C = (yA_L / SubHeightC) + (mvCLX[1] >> 3) + y_C \quad (8-225)$$

$$xFrac_C = mvCLX[0] \& 7 \quad (8-226)$$

$$yFrac_C = mvCLX[1] \& 7 \quad (8-227)$$

- Otherwise, if chroma_format_idc is equal to 2,

$$xInt_C = (xA_L / SubWidthC) + (mvCLX[0] >> 3) + x_C \quad (8-228)$$

$$yInt_C = (yA_L / SubHeightC) + (mvCLX[1] >> 2) + y_C \quad (8-229)$$

$$xFrac_C = mvCLX[0] \& 7 \quad (8-230)$$

$$yFrac_C = (mvCLX[1] \& 3) << 1 \quad (8-231)$$

- Otherwise (chroma_format_idc is equal to 3),

$$xInt_C = (xA_L / SubWidthC) + (mvCLX[0] >> 2) + x_C \quad (8-232)$$

$$yInt_C = (yA_L / SubHeightC) + (mvCLX[1] >> 2) + y_C \quad (8-233)$$

$$xFrac_C = (mvCLX[0] \& 3) << 1 \quad (8-234)$$

$$yFrac_C = (mvCLX[1] \& 3) << 1 \quad (8-235)$$

- The prediction sample value $predPartLX_{Cb}[x_C, y_C]$ is derived by invoking the process specified in subclause 8.4.2.2.2 with $(xInt_C, yInt_C)$, $(xFrac_C, yFrac_C)$ and $refPicLX_{Cb}$ given as input.
- The prediction sample value $predPartLX_{Cr}[x_C, y_C]$ is derived by invoking the process specified in subclause 8.4.2.2.2 with $(xInt_C, yInt_C)$, $(xFrac_C, yFrac_C)$ and $refPicLX_{Cr}$ given as input.

8.4.2.2.1 Luma sample interpolation process

Inputs to this process are

- a luma location in full-sample units $(xInt_L, yInt_L)$,
- a luma location offset in fractional-sample units $(xFrac_L, yFrac_L)$, and
- the luma sample array of the selected reference picture $refPicLX_L$

Output of this process is a predicted luma sample value $predPartLX_L[x_L, y_L]$.

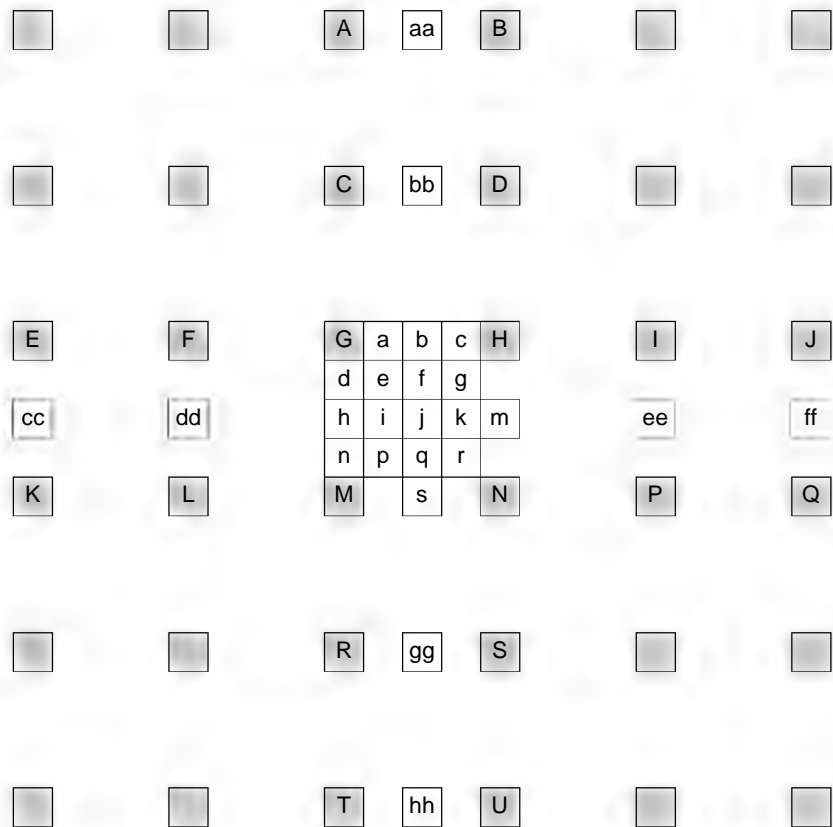

Figure 8-4 – Integer samples (shaded blocks with upper-case letters) and fractional sample positions (un-shaded blocks with lower-case letters) for quarter sample luma interpolation

The variable $\text{refPicHeightEffective}_L$, which is the height of the effective reference picture luma array, is derived as follows.

- If MbaffFrameFlag is equal to 0 or $\text{mb_field_decoding_flag}$ is equal to 0, $\text{refPicHeightEffective}_L$ is set equal to $\text{PicHeightInSamples}_L$.
- Otherwise (MbaffFrameFlag is equal to 1 and $\text{mb_field_decoding_flag}$ is equal to 1), $\text{refPicHeightEffective}_L$ is set equal to $\text{PicHeightInSamples}_L / 2$.

In Figure 8-4, the positions labelled with upper-case letters within shaded blocks represent luma samples at full-sample locations inside the given two-dimensional array refPicLX_L of luma samples. These samples may be used for generating the predicted luma sample value $\text{predPartLX}_L[x_L, y_L]$. The locations (xZ_L, yZ_L) for each of the corresponding luma samples Z , where Z may be A, B, C, D, E, F, G, H, I, J, K, L, M, N, P, Q, R, S, T, or U, inside the given array refPicLX_L of luma samples are derived as follows:

$$\begin{aligned} xZ_L &= \text{Clip3}(0, \text{PicWidthInSamples}_L - 1, x\text{Int}_L + xDZ_L) \\ yZ_L &= \text{Clip3}(0, \text{refPicHeightEffective}_L - 1, y\text{Int}_L + yDZ_L) \end{aligned} \quad (8-236)$$

Table 8-11 specifies (xDZ_L, yDZ_L) for different replacements of Z .

Table 8-11 – Differential full-sample luma locations

Z	A	B	C	D	E	F	G	H	I	J	K	L	M	N	P	Q	R	S	T	U
xDZ_L	0	1	0	1	-2	-1	0	1	2	3	-2	-1	0	1	2	3	0	1	0	1
yDZ_L	-2	-2	-1	-1	0	0	0	0	0	0	1	1	1	1	1	1	2	2	3	3

Given the luma samples ‘A’ to ‘U’ at full-sample locations (x_{A_L}, y_{A_L}) to (x_{U_L}, y_{U_L}), the luma samples ‘a’ to ‘s’ at fractional sample positions are derived by the following rules. The luma prediction values at half sample positions are derived by applying a 6-tap filter with tap values (1, -5, 20, 20, -5, 1). The luma prediction values at quarter sample positions are derived by averaging samples at full and half sample positions. The process for each fractional position is described below.

- The samples at half sample positions labelled b are derived by first calculating intermediate values denoted as b_1 by applying the 6-tap filter to the nearest integer position samples in the horizontal direction. The samples at half sample positions labelled h are derived by first calculating intermediate values denoted as h_1 by applying the 6-tap filter to the nearest integer position samples in the vertical direction:

$$b_1 = (E - 5 * F + 20 * G + 20 * H - 5 * I + J) \quad (8-237)$$

$$h_1 = (A - 5 * C + 20 * G + 20 * M - 5 * R + T) \quad (8-238)$$

The final prediction values b and h are derived using:

$$b = \text{Clip1}_Y((b_1 + 16) \gg 5) \quad (8-239)$$

$$h = \text{Clip1}_Y((h_1 + 16) \gg 5) \quad (8-240)$$

- The samples at half sample position labelled as j are derived by first calculating intermediate value denoted as j_1 by applying the 6-tap filter to the intermediate values of the closest half sample positions in either the horizontal or vertical direction because these yield an equal result.

$$j_1 = cc - 5 * dd + 20 * h_1 + 20 * m_1 - 5 * ee + ff, \text{ or} \quad (8-241)$$

$$j_1 = aa - 5 * bb + 20 * b_1 + 20 * s_1 - 5 * gg + hh \quad (8-242)$$

where intermediate values denoted as aa, bb, gg, s_1 and hh are derived by applying the 6-tap filter horizontally in the same manner as the derivation of b_1 and intermediate values denoted as cc, dd, ee, m_1 and ff are derived by applying the 6-tap filter vertically in the same manner as the derivation of h_1 . The final prediction value j are derived using:

$$j = \text{Clip1}_Y((j_1 + 512) \gg 10) \quad (8-243)$$

- The final prediction values s and m are derived from s_1 and m_1 in the same manner as the derivation of b and h, as given by:

$$s = \text{Clip1}_Y((s_1 + 16) \gg 5) \quad (8-244)$$

$$m = \text{Clip1}_Y((m_1 + 16) \gg 5) \quad (8-245)$$

- The samples at quarter sample positions labelled as a, c, d, n, f, i, k, and q are derived by averaging with upward rounding of the two nearest samples at integer and half sample positions using:

$$a = (G + b + 1) \gg 1 \quad (8-246)$$

$$c = (H + b + 1) \gg 1 \quad (8-247)$$

$$d = (G + h + 1) \gg 1 \quad (8-248)$$

$$n = (M + h + 1) \gg 1 \quad (8-249)$$

$$f = (b + j + 1) \gg 1 \quad (8-250)$$

$$i = (h + j + 1) \gg 1 \quad (8-251)$$

$$k = (j + m + 1) \gg 1 \quad (8-252)$$

$$q = (j + s + 1) \gg 1. \quad (8-253)$$

- The samples at quarter sample positions labelled as e, g, p, and r are derived by averaging with upward rounding of the two nearest samples at half sample positions in the diagonal direction using

$$e = (b + h + 1) \gg 1 \quad (8-254)$$

$$g = (b + m + 1) \gg 1 \quad (8-255)$$

$$p = (h + s + 1) \gg 1 \quad (8-256)$$

$$r = (m + s + 1) \gg 1. \quad (8-257)$$

The luma location offset in fractional-sample units ($x_{\text{Frac}_L}, y_{\text{Frac}_L}$) specifies which of the generated luma samples at full-sample and fractional-sample locations is assigned to the predicted luma sample value $\text{predPartLX}_L[x_L, y_L]$. This assignment is done according to Table 8-12. The value of $\text{predPartLX}_L[x_L, y_L]$ is the output.

Table 8-12 – Assignment of the luma prediction sample $\text{predPartLX}_L[x_L, y_L]$

$x\text{Frac}_L$	0	0	0	0	1	1	1	1	2	2	2	2	3	3	3	3
$y\text{Frac}_L$	0	1	2	3	0	1	2	3	0	1	2	3	0	1	2	3

8.4.2.2.2 Chroma sample interpolation process

This process shall only be invoked when chroma_format_idc is not equal to 0 (monochrome).

Inputs to this process are

- a chroma location in full-sample units ($x\text{Int}_C, y\text{Int}_C$),
- a chroma location offset in fractional-sample units ($x\text{Frac}_C, y\text{Frac}_C$), and
- chroma component samples from the selected reference picture refPicLX_C .

Output of this process is a predicted chroma sample value $\text{predPartLX}_C[x_C, y_C]$.

In Figure 8-5, the positions labelled with A, B, C, and D represent chroma samples at full-sample locations inside the given two-dimensional array refPicLX_C of chroma samples.

Figure 8-5 – Fractional sample position dependent variables in chroma interpolation and surrounding integer position samples A, B, C, and D

The variable $\text{refPicHeightEffective}_C$, which is the height of the effective reference picture chroma array, is derived as follows.

- If MbaffFrameFlag is equal to 0 or $\text{mb_field_decoding_flag}$ is equal to 0, $\text{refPicHeightEffective}_C$ is set equal to $\text{PicHeightInSamples}_C$.
- Otherwise (MbaffFrameFlag is equal to 1 and $\text{mb_field_decoding_flag}$ is equal to 1), $\text{refPicHeightEffective}_C$ is set equal to $\text{PicHeightInSamples}_C / 2$.

The sample coordinates specified in Equations 8-258 through 8-265 are used for generating the predicted chroma sample value $\text{predPartLX}_C[x_C, y_C]$.

$$x_{A_C} = \text{Clip3}(0, \text{PicWidthInSamples}_C - 1, x\text{Int}_C) \quad (8-258)$$

$$x_{B_C} = \text{Clip3}(0, \text{PicWidthInSamples}_C - 1, x\text{Int}_C + 1) \quad (8-259)$$

$$x_{C_C} = \text{Clip3}(0, \text{PicWidthInSamples}_C - 1, x\text{Int}_C) \quad (8-260)$$

$$x_{D_C} = \text{Clip3}(0, \text{PicWidthInSamples}_C - 1, x\text{Int}_C + 1) \quad (8-261)$$

$$y_{A_C} = \text{Clip3}(0, \text{refPicHeightEffective}_C - 1, y\text{Int}_C) \quad (8-262)$$

$$y_{B_C} = \text{Clip3}(0, \text{refPicHeightEffective}_C - 1, y\text{Int}_C) \quad (8-263)$$

$$y_{C_C} = \text{Clip3}(0, \text{refPicHeightEffective}_C - 1, y\text{Int}_C + 1) \quad (8-264)$$

$$y_{D_C} = \text{Clip3}(0, \text{refPicHeightEffective}_C - 1, y\text{Int}_C + 1) \quad (8-265)$$

Given the chroma samples A, B, C, and D at full-sample locations specified in Equations 8-258 through 8-265, the predicted chroma sample value $\text{predPartLXC}[x_C, y_C]$ is derived as follows:

$$\text{predPartLXC}[x_C, y_C] = ((8 - x_{\text{Frac}_C}) * (8 - y_{\text{Frac}_C}) * A + x_{\text{Frac}_C} * (8 - y_{\text{Frac}_C}) * B + (8 - x_{\text{Frac}_C}) * y_{\text{Frac}_C} * C + x_{\text{Frac}_C} * y_{\text{Frac}_C} * D + 32) \gg 6 \quad (8-266)$$

8.4.2.3 Weighted sample prediction process

Inputs to this process are

- mbPartIdx : the current partition given by the partition index
- subMbPartIdx : the sub-macroblock partition index
- predFlagL0 and predFlagL1 : prediction list utilization flags
- predPartLXL : a $(\text{partWidth}) \times (\text{partHeight})$ array of prediction luma samples (with LX being replaced by L0 or L1 depending on predFlagL0 and predFlagL1)
- when chroma_format_idc is not equal to 0 (monochrome), predPartLXC_b and predPartLXC_r : $(\text{partWidthC}) \times (\text{partHeightC})$ arrays of prediction chroma samples, one for each of the chroma components Cb and Cr (with LX being replaced by L0 or L1 depending on predFlagL0 and predFlagL1)

Outputs of this process are

- predPart_L : a $(\text{partWidth}) \times (\text{partHeight})$ array of prediction luma samples and
- when chroma_format_idc is not equal to 0 (monochrome), predPart_{Cb} , and predPart_{Cr} : $(\text{partWidthC}) \times (\text{partHeightC})$ arrays of prediction chroma samples, one for each of the chroma components Cb and Cr.

For macroblocks or partitions with predFlagL0 equal to 1 in P and SP slices, the following applies.

- If $\text{weighted_pred_flag}$ is equal to 0, the default weighted sample prediction process as described in subclause 8.4.2.3.1 is invoked with the same inputs and outputs as the process described in this subclause.
- Otherwise ($\text{weighted_pred_flag}$ is equal to 1), the explicit weighted prediction process as described in subclause 8.4.2.3.2 is invoked with the same inputs and outputs as the process described in this subclause.

For macroblocks or partitions with predFlagL0 or predFlagL1 equal to 1 in B slices, the following applies.

- If $\text{weighted_bipred_idc}$ is equal to 0, the default weighted sample prediction process as described in subclause 8.4.2.3.1 is invoked with the same inputs and outputs as the process described in this subclause.
- Otherwise, if $\text{weighted_bipred_idc}$ is equal to 1, the explicit weighted sample prediction process as described in subclause 8.4.2.3.2, for macroblocks or partitions with predFlagL0 or predFlagL1 equal to 1 with the same inputs and outputs as the process described in this subclause.
- Otherwise ($\text{weighted_bipred_idc}$ is equal to 2), the following applies.
 - If predFlagL0 is equal to 1 and predFlagL1 is equal to 1, the implicit weighted sample prediction as described in subclause 8.4.2.3.2 is invoked with the same inputs and outputs as the process described in this subclause.
 - Otherwise (predFlagL0 or predFlagL1 are equal to 1 but not both), the default weighted sample prediction process as described in subclause 8.4.2.3.1 is invoked with the same inputs and outputs as the process described in this subclause.

8.4.2.3.1 Default weighted sample prediction process

Input to this process are the same as specified in subclause 8.4.2.3.

Output of this process are the same as specified in subclause 8.4.2.3.

Depending on the available component for which the prediction block is derived, the following applies.

- If the luma sample prediction values $\text{predPart}_L[x, y]$ are derived, the following applies with C set equal to L, x set equal to 0 .. $\text{partWidth} - 1$, and y set equal to 0 .. $\text{partHeight} - 1$.
- Otherwise, if the chroma Cb component sample prediction values $\text{predPart}_{Cb}[x, y]$ are derived, the following applies with C set equal to Cb, x set equal to 0 .. $\text{partWidthC} - 1$, and y set equal to 0 .. $\text{partHeightC} - 1$.
- Otherwise (the chroma Cr component sample prediction values $\text{predPart}_{Cr}[x, y]$ are derived), the following applies with C set equal to Cr, x set equal to 0 .. $\text{partWidthC} - 1$, and y set equal to 0 .. $\text{partHeightC} - 1$.

The prediction sample values are derived as follows.

- If predFlagL0 is equal to 1 and predFlagL1 is equal to 0 for the current partition

$$\text{predPartC}[x, y] = \text{predPartL0C}[x, y] \quad (8-267)$$

- Otherwise, if predFlagL0 is equal to 0 and predFlagL1 is equal to 1 for the current partition

$$\text{predPartC}[x, y] = \text{predPartL1C}[x, y] \quad (8-268)$$

- Otherwise (predFlagL0 and predFlagL1 are equal to 1 for the current partition),

$$\text{predPartC}[x, y] = (\text{predPartL0C}[x, y] + \text{predPartL1C}[x, y] + 1) \gg 1. \quad (8-269)$$

8.4.2.3.2 Weighted sample prediction process

Input to this process are the same as specified in subclause 8.4.2.3.

Output of this process are the same as specified in subclause 8.4.2.3.

Depending on the available component for which the prediction block is derived, the following applies.

- If the luma sample prediction values $\text{predPartL}[x, y]$ are derived, the following applies with C set equal to L, x set equal to 0 .. partWidth - 1, and y set equal to 0 .. partHeight - 1.
- Otherwise, if the chroma Cb component sample prediction values $\text{predPartCb}[x, y]$ are derived, the following applies with C set equal to Cb, x set equal to 0 .. partWidthC - 1, and y set equal to 0 .. partHeightC - 1.
- Otherwise (the chroma Cr component sample prediction values $\text{predPartCr}[x, y]$ are derived), the following applies with C set equal to Cr, x set equal to 0 .. partWidthC - 1, and y set equal to 0 .. partHeightC - 1.

The prediction sample values are derived as follows

- If the partition $\text{mbPartIdx} \backslash \text{subMbPartIdx}$ has predFlagL0 equal to 1 and predFlagL1 equal to 0, the final predicted sample values $\text{predPartC}[x, y]$ are derived by

$$\begin{aligned} &\text{if}(\log\text{WD} \geq 1) \\ &\quad \text{predPartC}[x, y] = \text{Clip1C}((\text{predPartL0C}[x, y] * w_0 + 2^{\log\text{WD} - 1}) \gg \log\text{WD}) + o_0) \\ &\text{else} \\ &\quad \text{predPartC}[x, y] = \text{Clip1C}(\text{predPartL0C}[x, y] * w_0 + o_0) \end{aligned} \quad (8-270)$$

- Otherwise, if the partition $\text{mbPartIdx} \backslash \text{subMbPartIdx}$ has predFlagL0 equal to 0 and predFlagL1 equal to 1, the final predicted sample values $\text{predPartC}[x, y]$ are derived by

$$\begin{aligned} &\text{if}(\log\text{WD} \geq 1) \\ &\quad \text{predPartC}[x, y] = \text{Clip1C}((\text{predPartL1C}[x, y] * w_1 + 2^{\log\text{WD} - 1}) \gg \log\text{WD}) + o_1) \\ &\text{else} \\ &\quad \text{predPartC}[x, y] = \text{Clip1C}(\text{predPartL1C}[x, y] * w_1 + o_1) \end{aligned} \quad (8-271)$$

- Otherwise (the partition $\text{mbPartIdx} \backslash \text{subMbPartIdx}$ has both predFlagL0 and predFlagL1 equal to 1), the final predicted sample values $\text{predPartC}[x, y]$ are derived by

$$\text{predPartC}[x, y] = \text{Clip1C}((\text{predPartL0C}[x, y] * w_0 + \text{predPartL1C}[x, y] * w_1 + 2^{\log\text{WD}}) \gg (\log\text{WD} + 1)) + ((o_0 + o_1 + 1) \gg 1) \quad (8-272)$$

The variables in the above derivation for the prediction samples are derived as follows.

- If weighted_bipred_idc is equal to 2 and the slice_type is equal to B, implicit mode weighted prediction is used as follows.

$$\log\text{WD} = 5 \quad (8-273)$$

$$o_0 = 0 \quad (8-274)$$

$$o_1 = 0 \quad (8-275)$$

and w_0 and w_1 are derived as follows.

- The variables currPicOrField, pic0, and pic1 are derived as follows:
 - If field_pic_flag is equal to 0 and the current macroblock is a field macroblock, the following applies.
 - currPicOrField is the field of the current picture CurrPic that has the same parity as the current macroblock.
 - The variable pic0 is derived as follows.
 - If refIdxL0 % 2 is equal to 0, pic0 is the field of RefPicList0[refIdxL0 / 2] that has the same parity as the current macroblock.
 - Otherwise (refIdxL0 % 2 is not equal to 0), pic0 is the field of RefPicList0[refIdxL0 / 2] that has the opposite parity of the current macroblock.
 - The variable pic1 is derived as follows.
 - If refIdxL1 % 2 is equal to 0, pic1 is the field of RefPicList1[refIdxL1 / 2] that has the same parity as the current macroblock.
 - Otherwise (refIdxL1 % 2 is not equal to 0), pic1 is the field of RefPicList1[refIdxL1 / 2] that has the opposite parity of the current macroblock.
 - Otherwise (field_pic_flag is equal to 1 or the current macroblock is a frame macroblock), currPicOrField is the current picture CurrPic, pic1 is RefPicList1[refIdxL1], and pic0 is RefPicList0[refIdxL0].
- The variables tb, td, tx, and DistScaleFactor are derived from the values of currPicOrField, pic0, pic1 using Equations 8-198, 8-199, 8-194, and 8-195, respectively.
- If DiffPicOrderCnt(pic1, pic0) is equal to 0 or one or both of pic1 and pic0 is marked as "used for long-term reference" or (DistScaleFactor >> 2) < -64 or (DistScaleFactor >> 2) > 128, w_0 and w_1 are derived as

$$w_0 = 32 \quad (8-276)$$

$$w_1 = 32 \quad (8-277)$$

- Otherwise,

$$w_0 = 64 - (\text{DistScaleFactor} \gg 2) \quad (8-278)$$

$$w_1 = \text{DistScaleFactor} \gg 2 \quad (8-279)$$

- Otherwise (weighted_pred_flag is equal to 1 in P or SP slices or weighted_bipred_idc equal to 1 in B slices), explicit mode weighted prediction is used as follows.

- The variables refIdxL0WP and refIdxL1WP are derived as follows.
 - If MbaffFrameFlag is equal to 1 and the current macroblock is a field macroblock

$$\text{refIdxL0WP} = \text{refIdxL0} \gg 1 \quad (8-280)$$

$$\text{refIdxL1WP} = \text{refIdxL1} \gg 1 \quad (8-281)$$

- Otherwise (MbaffFrameFlag is equal to 0 or the current macroblock is a frame macroblock),

$$\text{refIdxL0WP} = \text{refIdxL0} \quad (8-282)$$

$$\text{refIdxL1WP} = \text{refIdxL1} \quad (8-283)$$

– The variables $\log\text{WD}$, w_0 , w_1 , o_0 , and o_1 are derived as follows.

– If C in $\text{predPart}_C[x, y]$ is replaced by L for luma samples

$$\log\text{WD} = \text{luma_log2_weight_denom} \quad (8-284)$$

$$w_0 = \text{luma_weight_l0}[\text{refIdxL0WP}] \quad (8-285)$$

$$w_1 = \text{luma_weight_l1}[\text{refIdxL1WP}] \quad (8-286)$$

$$o_0 = \text{luma_offset_l0}[\text{refIdxL0WP}] * (1 \ll (\text{BitDepth}_Y - 8)) \quad (8-287)$$

$$o_1 = \text{luma_offset_l1}[\text{refIdxL1WP}] * (1 \ll (\text{BitDepth}_Y - 8)) \quad (8-288)$$

– Otherwise (C in $\text{predPart}_C[x, y]$ is replaced by C_b or C_r for chroma samples, with $iCbCr = 0$ for C_b , $iCbCr = 1$ for C_r),

$$\log\text{WD} = \text{chroma_log2_weight_denom} \quad (8-289)$$

$$w_0 = \text{chroma_weight_l0}[\text{refIdxL0WP}][iCbCr] \quad (8-290)$$

$$w_1 = \text{chroma_weight_l1}[\text{refIdxL1WP}][iCbCr] \quad (8-291)$$

$$o_0 = \text{chroma_offset_l0}[\text{refIdxL0WP}][iCbCr] * (1 \ll (\text{BitDepth}_C - 8)) \quad (8-292)$$

$$o_1 = \text{chroma_offset_l1}[\text{refIdxL1WP}][iCbCr] * (1 \ll (\text{BitDepth}_C - 8)) \quad (8-293)$$

When explicit mode weighted prediction is used and the partition $\text{mbPartIdx} \backslash \text{subMbPartIdx}$ has both predFlagL0 and predFlagL1 equal to 1, the following constraint shall be obeyed

$$-128 \leq w_0 + w_1 \leq ((\log\text{WD} == 7) ? 127 : 128) \quad (8-294)$$

NOTE – For implicit mode weighted prediction, weights w_0 and w_1 are each guaranteed to be in the range of -64..128 and the constraint expressed in Equation 8-294, although not explicitly imposed, will always be met. For explicit mode weighted prediction with $\log\text{WD}$ equal to 7, when one of the two weights w_0 or w_1 is inferred to be equal to 128 (as a consequence of $\text{luma_weight_l0_flag}$, $\text{luma_weight_l1_flag}$, $\text{chroma_weight_l0_flag}$, or $\text{chroma_weight_l1_flag}$ equal to 0), the other weight (w_1 or w_0) must have a negative value in order for the constraint expressed in Equation 8-294 to hold (and therefore the other flag $\text{luma_weight_l0_flag}$, $\text{luma_weight_l1_flag}$, $\text{chroma_weight_l0_flag}$, or $\text{chroma_weight_l1_flag}$ must be equal to 1).

8.5 Transform coefficient decoding process and picture construction process prior to deblocking filter process

Inputs to this process are Intra16x16DCLevel (if available), Intra16x16ACLevel (if available), LumaLevel (if available), LumaLevel8x8 (if available), ChromaDCLevel (if available), ChromaACLevel (if available), and available Inter or Intra prediction sample arrays for the current macroblock for the applicable components pred_L , pred_{C_b} , or pred_{C_r} .

NOTE 1 – When decoding a macroblock in Intra_4x4 (or Intra_8x8) prediction mode, the luma component of the macroblock prediction array may not be complete, since for each $4x4$ (or $8x8$) luma block, the Intra_4x4 (or Intra_8x8) prediction process for luma samples as specified in subclause 8.3.1 (or 8.3.2) and the process specified in this subclause are iterated.

Outputs of this process are the constructed sample arrays prior to the deblocking filter process for the applicable components S'_L , S'_{C_b} , or S'_{C_r} .

NOTE 2 – When decoding a macroblock in Intra_4x4 (or Intra_8x8) prediction mode, the luma component of the macroblock constructed sample arrays prior to the deblocking filter process may not be complete, since for each $4x4$ (or $8x8$) luma block, the

Intra_4x4 (or Intra_8x8) prediction process for luma samples as specified in subclause 8.3.1 (or 8.3.2) and the process specified in this subclause are iterated.

This subclause specifies transform coefficient decoding and picture construction prior to the deblocking filter process.

When the current macroblock is coded as P_Skip or B_Skip, all values of LumaLevel, LumaLevel8x8, ChromaDCLevel, ChromaACLevel are set equal to 0 for the current macroblock.

When residual_colour_transform_flag is equal to 1, the residual colour transform process as specified in subclause 8.5.13 is invoked.

8.5.1 Specification of transform decoding process for 4x4 luma residual blocks

This specification applies when transform_size_8x8_flag is equal to 0.

When the current macroblock prediction mode is not equal to Intra_16x16, the variable LumaLevel contains the levels for the luma transform coefficients. For a 4x4 luma block indexed by luma4x4BlkIdx = 0..15, the following ordered steps are specified.

1. The inverse transform coefficient scanning process as described in subclause 8.5.5 is invoked with LumaLevel[luma4x4BlkIdx] as the input and the two-dimensional array c as the output.
2. The scaling and transformation process for residual 4x4 blocks as specified in subclause 8.5.10 is invoked with c as the input and r as the output.
3. When residual_colour_transform_flag is equal to 1, the variable $R_{Y,ij}$ is set equal to r_{ij} with $i, j = 0..3$ and this process is suspended until after completion of the residual colour transform process as specified in subclause 8.5.13, after the completion of which, the variable r_{ij} is set equal to $R_{G,ij}$ with $i, j = 0..3$ and this process is continued.
4. The position of the upper-left sample of a 4x4 luma block with index luma4x4BlkIdx inside the macroblock is derived by invoking the inverse 4x4 luma block scanning process in subclause 6.4.3 with luma4x4BlkIdx as the input and the output being assigned to (xO, yO).
5. The 4x4 array u with elements u_{ij} for $i, j = 0..3$ is derived as

$$u_{ij} = \text{Clip1}_Y(\text{pred}_L[xO + j, yO + i] + r_{ij}) \quad (8-295)$$

When qpprime_y_zero_transform_bypass_flag is equal to 1 and QP'_Y is equal to 0, the bitstream shall not contain data that result in a value of u_{ij} as computed by Equation 8-295 that is not equal to $\text{pred}_L[xO + j, yO + i] + r_{ij}$.

6. The picture construction process prior to deblocking filter process in subclause 8.5.12 is invoked with luma4x4BlkIdx and u as the inputs.

8.5.2 Specification of transform decoding process for luma samples of Intra_16x16 macroblock prediction mode

When the current macroblock prediction mode is equal to Intra_16x16, the variables Intra16x16DCLevel and Intra16x16ACLevel contain the levels for the luma transform coefficients. The transform coefficient decoding proceeds in the following ordered steps:

1. The 4x4 luma DC transform coefficients of all 4x4 luma blocks of the macroblock are decoded.
 - a. The inverse transform coefficient scanning process as described in subclause 8.5.5 is invoked with Intra16x16DCLevel as the input and the two-dimensional array c as the output.
 - b. The scaling and transformation process for luma DC transform coefficients for Intra_16x16 macroblock type as specified in subclause 8.5.8 is invoked with c as the input and dcY as the output.
2. For a 4x4 luma block indexed by luma4x4BlkIdx = 0..15, the following ordered steps are specified.
 - a. The variable lumaList, which is a list of 16 entries, is derived. The first entry of lumaList is the corresponding value from the array dcY. Figure 8-6 shows the assignment of the indices of the array dcY to the luma4x4BlkIdx. The two numbers in the small squares refer to indices i and j in dcY_{ij} , and the numbers in large squares refer to luma4x4BlkIdx.

00 0	01 1	02 4	03 5
10 2	11 3	12 6	13 7
20 8	21 9	22 12	23 13
30 10	31 11	32 14	33 15

Figure 8-6 – Assignment of the indices of dcY to luma4x4BlkIdx

The elements in lumaList with index $k = 1..15$ are specified as

$$\text{lumaList}[k] = \text{Intra16x16ACLevel}[\text{luma4x4BlkIdx}][k - 1] \quad (8-296)$$

- b. The inverse transform coefficient scanning process as described in subclause 8.5.5 is invoked with lumaList as the input and the two-dimensional array c as the output.
- c. The scaling and transformation process for residual 4x4 blocks as specified in subclause 8.5.10 is invoked with c as the input and r as the output.
- d. When residual_colour_transform_flag is equal to 1, the variable $R_{Y,ij}$ is set equal to r_{ij} with $i, j = 0..3$ and this process is suspended until after completion of the residual colour transform process as specified in subclause 8.5.13, after the completion of which, the variable r_{ij} is set equal to $R_{G,ij}$ with $i, j = 0..3$ and this process is continued.
- e. The position of the upper-left sample of a 4x4 luma block with index luma4x4BlkIdx inside the macroblock is derived by invoking the inverse 4x4 luma block scanning process in subclause 6.4.3 with luma4x4BlkIdx as the input and the output being assigned to (xO, yO).
- f. The 4x4 array u with elements u_{ij} for $i, j = 0..3$ is derived as

$$u_{ij} = \text{Clip1}_Y(\text{pred}_L[xO + j, yO + i] + r_{ij}) \quad (8-297)$$

When qpprime_y_zero_transform_bypass_flag is equal to 1 and QP'_Y is equal to 0, the bitstream shall not contain data that result in a value of u_{ij} as computed by 8-297 that is not equal to $\text{pred}_L[xO + j, yO + i] + r_{ij}$.

- g. The picture construction process prior to deblocking filter process in subclause 8.5.12 is invoked with luma4x4BlkIdx and u as the inputs.

8.5.3 Specification of transform decoding process for 8x8 luma residual blocks

This specification applies when transform_size_8x8_flag is equal to 1.

The variable LumaLevel8x8[luma8x8BlkIdx] with luma8x8BlkIdx = 0..3 contains the levels for the luma transform coefficients for the luma 8x8 block with index luma8x8BlkIdx.

For an 8x8 luma block indexed by luma8x8BlkIdx = 0..3, the following ordered steps are specified.

1. The inverse scanning process for 8x8 luma transform coefficients as described in subclause 8.5.6 is invoked with LumaLevel8x8[luma8x8BlkIdx] as the input and the two-dimensional array c as the output.
2. The scaling and transformation process for residual 8x8 blocks as specified in subclause 8.5.11 is invoked with c as the input and r as the output.
3. When residual_colour_transform_flag is equal to 1, the variable $R_{Y,ij}$ is set equal to r_{ij} with $i, j = 0..7$ and this process is suspended until after completion of the residual colour transform process as specified in subclause 8.5.13, after the completion of which, the variable r_{ij} is set equal to $R_{G,ij}$ with $i, j = 0..7$ and this process is continued.

4. The position of the upper-left sample of an 8x8 luma block with index luma8x8BlkIdx inside the macroblock is derived by invoking the inverse 8x8 luma block scanning process in subclause 6.4.4 with luma8x8BlkIdx as the input and the output being assigned to (xO, yO).
5. The 8x8 array u with elements u_{ij} for $i, j = 0..7$ is derived as

$$u_{ij} = \text{Clip1}_Y(\text{pred}_L[xO + j, yO + i] + r_{ij}) \quad (8-298)$$

When `qpprime_y_zero_transform_bypass_flag` is equal to 1 and QP'_Y is equal to 0, the bitstream shall not contain data that result in a value of u_{ij} as computed by Equation 8-298 that is not equal to $\text{pred}_L[xO + j, yO + i] + r_{ij}$.

6. The picture construction process prior to deblocking filter process in subclause 8.5.12 is invoked with luma8x8BlkIdx and u as the inputs.

8.5.4 Specification of transform decoding process for chroma samples

This process is invoked for each chroma component Cb and Cr separately.

For each chroma component, the variables `ChromaDCLevel[iCbCr]` and `ChromaACLevel[iCbCr]`, with `iCbCr` set equal to 0 for Cb and `iCbCr` set equal to 1 for Cr, contain the levels for both components of the chroma transform coefficients.

Let the variable `numChroma4x4Blks` be set equal to $(\text{MbWidthC} / 4) * (\text{MbHeightC} / 4)$.

For each chroma component, the transform decoding proceeds separately in the following ordered steps:

1. The `numChroma4x4Blks` chroma DC transform coefficients of the 4x4 chroma blocks of the component indexed by `iCbCr` of the macroblock are decoded.

- a. Depending on the variable `chroma_format_idc`, the following applies.
 - If `chroma_format_idc` is equal to 1, the 2x2 array c is derived using the inverse raster scanning process applied to `ChromaDCLevel` as follows

$$c = \begin{bmatrix} \text{ChromaDCLevel}[iCbCr][0] & \text{ChromaDCLevel}[iCbCr][1] \\ \text{ChromaDCLevel}[iCbCr][2] & \text{ChromaDCLevel}[iCbCr][3] \end{bmatrix} \quad (8-299)$$

- Otherwise, if `chroma_format_idc` is equal to 2, the 2x4 array c is derived using the inverse raster scanning process applied to `ChromaDCLevel` as follows

$$c = \begin{bmatrix} \text{ChromaDCLevel}[iCbCr][0] & \text{ChromaDCLevel}[iCbCr][2] \\ \text{ChromaDCLevel}[iCbCr][1] & \text{ChromaDCLevel}[iCbCr][5] \\ \text{ChromaDCLevel}[iCbCr][3] & \text{ChromaDCLevel}[iCbCr][6] \\ \text{ChromaDCLevel}[iCbCr][4] & \text{ChromaDCLevel}[iCbCr][7] \end{bmatrix} \quad (8-300)$$

- Otherwise (`chroma_format_idc` is equal to 3), the inverse scanning process for transform coefficients as specified in subclause 8.5.5 is invoked with `ChromaDCLevel[iCbCr]` as the input and the two-dimensional 4x4 array c as the output.
- b. The scaling and transformation process for chroma DC transform coefficients as specified in subclause 8.5.9 is invoked with c as the input and `dcC` as the output.
2. For each 4x4 chroma block indexed by `chroma4x4BlkIdx = 0..numChroma4x4Blks – 1` of the component indexed by `iCbCr`, the following ordered steps are specified.
 - a. The variable `chromaList`, which is a list of 16 entries, is derived. The first entry of `chromaList` is the corresponding value from the array `dcC`. Figure 8-7 shows the assignment of the indices of the array `dcC` to the `chroma4x4BlkIdx`. The two numbers in the small squares refer to indices i and j in `dcCij`, and the numbers in large squares refer to `chroma4x4BlkIdx`.

Figure 8-7 – Assignment of the indices of dcC to chroma4x4BlkIdx:

(a) chroma_format_idc equal to 1, (b) chroma_format_idc equal to 2, (c) chroma_format_idc equal to 3

The elements in chromaList with index $k = 1..15$ are specified as

$$\text{chromaList}[k] = \text{ChromaACLevel}[\text{chroma4x4BlkIdx}][k - 1] \quad (8-301)$$

- b. The inverse scanning process for transform coefficients as specified in subclause 8.5.9 is invoked with chromaList as the input and the two-dimensional array c as the output.
- c. The scaling and transformation process for residual 4x4 blocks as specified in subclause 8.5.10 is invoked with c as the input and r as the output.
- d. Depending on the variable chroma_format_idc, the position of the upper-left sample of a 4x4 chroma block with index chroma4x4BlkIdx inside the macroblock is derived as follows.

- If chroma_format_idc is equal to 1 or 2, the following applies.

$$xO = \text{InverseRasterScan}(\text{chroma4x4BlkIdx}, 4, 4, 8, 0) \quad (8-302)$$

$$yO = \text{InverseRasterScan}(\text{chroma4x4BlkIdx}, 4, 4, 8, 1) \quad (8-303)$$

- Otherwise (chroma_format_idc is equal to 3), the following applies.

$$xO = \text{InverseRasterScan}(\text{chroma4x4BlkIdx} / 4, 8, 8, 16, 0) + \text{InverseRasterScan}(\text{chroma4x4BlkIdx} \% 4, 4, 4, 8, 0) \quad (8-304)$$

$$yO = \text{InverseRasterScan}(\text{chroma4x4BlkIdx} / 4, 8, 8, 16, 1) + \text{InverseRasterScan}(\text{chroma4x4BlkIdx} \% 4, 4, 4, 8, 1) \quad (8-305)$$

- e. When residual_colour_transform_flag is equal to 1, the variable xO' is set equal to $xO \% (4 \ll \text{transform_size_8x8_flag})$, the variable yO' is set equal to $yO \% (4 \ll \text{transform_size_8x8_flag})$, and the following applies.

- If this process is invoked for the chroma component Cb, the variable $R_{Cb,mn}$ is set equal to r_{ij} with $i, j = 0..3$, $m = xO' + i$, $n = yO' + j$, and this process is suspended until after completion of the residual colour transform process as specified in subclause 8.5.13, after which the variable r_{ij} is set equal to $R_{B,mn}$ with $i, j = 0..3$, $m = xO' + i$, $n = yO' + j$ and this process is continued.

- Otherwise (this process is invoked for the chroma component Cr), the variable $R_{Cr,mn}$ is set equal to r_{ij} with $i, j = 0..3$, $m = xO' + i$, $n = yO' + j$ and this process is suspended until after the completion of the residual colour transform process as specified in subclause 8.5.13, after which the variable r_{ij} is set equal to $R_{R,mn}$ with $i, j = 0..3$, $m = xO' + i$, $n = yO' + j$ and this process is continued.

- f. The 4x4 array u with elements u_{ij} for $i, j = 0..3$ is derived as

$$u_{ij} = \text{Clip1}_c(\text{pred}_c[xO + j, yO + i] + r_{ij}) \quad (8-306)$$

When `qpprime_y_zero_transform_bypass_flag` is equal to 1 and QP'_Y is equal to 0, the bitstream shall not contain data that result in a value of u_{ij} as computed by Equation 8-306 that is not equal to $\text{pred}_c[xO + j, yO + i] + r_{ij}$.

- g. The picture construction process prior to deblocking filter process in subclause 8.5.12 is invoked with `chroma4x4BlkIdx` and u as the inputs.

8.5.5 Inverse scanning process for transform coefficients

Input to this process is a list of 16 values.

Output of this process is a variable c containing a two-dimensional array of 4x4 values. In the case of transform coefficients, these 4x4 values represent levels assigned to locations in the transform block. In the case of applying the inverse scanning process to a scaling list, the output variable c contains a two-dimensional array representing a 4x4 scaling matrix.

The inverse scanning process for transform coefficients maps the sequence of transform coefficient levels to the transform coefficient level positions. Table 8-13 specifies the two mappings: inverse zig-zag scan and inverse field scan. The inverse zig-zag scan is used for transform coefficients in frame macroblocks and the inverse field scan is used for transform coefficients in field macroblocks.

The inverse scanning process for scaling lists maps the sequence of scaling list entries to the positions in the corresponding scaling matrix. For this mapping, the inverse zig-zag scan is used.

Figure 8-8 illustrates the scans.

Figure 8-8 – 4x4 block scans. (a) Zig-zag scan. (b) Field scan (informative)

Table 8-13 provides the mapping from the index idx of input list of 16 elements to indices i and j of the two-dimensional array c .

8.5.7 Derivation process for the chroma quantisation parameters and scaling function

Outputs of this process are:

- QP_C: the chroma quantisation parameter for each chroma component Cb and Cr
- QS_C: the additional chroma quantisation parameter for each chroma component Cb and Cr required for decoding SP and SI slices (if applicable)

NOTE 1 – QP quantisation parameter values QP_Y and QS_Y are always in the range of –QpBdOffset_Y to 51, inclusive. QP quantisation parameter values QP_C and QS_C are always in the range of –QpBdOffset_C to 51, inclusive.

The value of QP_C for a chroma component is determined from the current value of QP_Y and the value of chroma_qp_index_offset (for Cb) or second_chroma_qp_index_offset (for Cr).

NOTE 2 – The scaling equations are specified such that the equivalent transform coefficient level scaling factor doubles for every increment of 6 in QP_Y. Thus, there is an increase in the factor used for scaling of approximately 12 % for each increase of 1 in the value of QP_Y.

The value of QP_C for each chroma component is determined as specified in Table 8-15 based on the index denoted as qP_I.

The variable qP_{Offset} for each chroma component is derived as follows.

- If the chroma component is the Cb component, qP_{Offset} is specified as

$$qP_{\text{Offset}} = \text{chroma_qp_index_offset} \quad (8-307)$$

- Otherwise (the chroma component is the Cr component), qP_{Offset} is specified as

$$qP_{\text{Offset}} = \text{second_chroma_qp_index_offset} \quad (8-308)$$

The value of qP_I for each chroma component is derived as

$$qP_I = \text{Clip3}(-QpBdOffset_C, 51, QP_Y + qP_{\text{Offset}}) \quad (8-309)$$

The value of QP'_C for the chroma components is derived as

$$QP'_C = QP_C + QpBdOffset_C \quad (8-310)$$

The value of $BitDepth'_C$ for the chroma components is derived as

$$BitDepth'_C = BitDepth_C + residual_colour_transform_flag \quad (8-311)$$

Table 8-15 – Specification of QP_C as a function of qP_1

qP_1	<30	30	31	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47	48	49	50	51
QP_C	$=qP_1$	29	30	31	32	32	33	34	34	35	35	36	36	37	37	37	38	38	38	39	39	39	39

When the current slice is an SP or SI slice, QS_C is derived using the above process, substituting QP_Y with QS_Y and QP_C with QS_C .

The function $LevelScale(m, i, j)$ is specified as follows.

- The 4x4 matrix $weightScale(i, j)$ is specified as follows.
 - The variable $mbIsInterFlag$ is derived as follows.
 - If the current macroblock is coded using Inter macroblock prediction modes, $mbIsInterFlag$ is set equal to 1.
 - Otherwise (the current macroblock is coded using Intra macroblock prediction modes), $mbIsInterFlag$ is set equal to 0.
 - The variable $iYCbCr$ derived as follows.
 - If the input array c relates to a luma residual block, $iYCbCr$ is set equal to 0.
 - Otherwise, if the input array c relates to a chroma residual block and the chroma component is equal to Cb, $iYCbCr$ is set equal to 1.
 - Otherwise (the input array c relates to a chroma residual block and the chroma component is equal to Cr), $iYCbCr$ is set equal to 2.
- The inverse scanning process for transform coefficients as specified in subclause 8.5.5 is invoked with $ScalingList4x4[iYCbCr + ((mbIsInterFlag == 1) ? 3 : 0)]$ as the input and the output is assigned to the 4x4 matrix $weightScale$.

$$LevelScale(m, i, j) = weightScale(i, j) * normAdjust(m, i, j) \quad (8-312)$$

where

$$normAdjust(m, i, j) = \begin{cases} v_{m0} & \text{for } (i \% 2, j \% 2) \text{ equal to } (0,0), \\ v_{m1} & \text{for } (i \% 2, j \% 2) \text{ equal to } (1,1), \\ v_{m2} & \text{otherwise;} \end{cases} \quad (8-313)$$

where the first and second subscripts of v are row and column indices, respectively, of the matrix specified as:

$$v = \begin{bmatrix} 10 & 16 & 13 \\ 11 & 18 & 14 \\ 13 & 20 & 16 \\ 14 & 23 & 18 \\ 16 & 25 & 20 \\ 18 & 29 & 23 \end{bmatrix}. \quad (8-314)$$

The function $\text{LevelScale8x8}(m, i, j)$ is specified as follows:

- The 8x8 matrix $\text{weightScale8x8}(i, j)$ is specified as follows.
 - The variable mbIsInterFlag is derived as follows.
 - If the current macroblock is coded using Inter macroblock prediction modes, mbIsInterFlag is set equal to 1.
 - Otherwise (the current macroblock is coded using Intra macroblock prediction modes), mbIsInterFlag is set equal to 0.
- The inverse scanning process for 8x8 luma transform coefficients as specified in subclause 8.5.6 is invoked with $\text{ScalingList8x8}[\text{mbIsInterFlag}]$ as the input and the output is assigned to the 8x8 matrix weightScale8x8 .

$$\text{LevelScale8x8}(m, i, j) = \text{weightScale8x8}(i, j) * \text{normAdjust8x8}(m, i, j) \quad (8-315)$$

where

$$\text{normAdjust8x8}(m, i, j) = \begin{cases} v_{m0} & \text{for } (i \% 4, j \% 4) \text{ equal to } (0,0), \\ v_{m1} & \text{for } (i \% 2, j \% 2) \text{ equal to } (1,1), \\ v_{m2} & \text{for } (i \% 4, j \% 4) \text{ equal to } (2,2), \\ v_{m3} & \text{for } (i \% 4, j \% 2) \text{ equal to } (0,1) \text{ or } (i \% 2, j \% 4) \text{ equal to } (1,0), \\ v_{m4} & \text{for } (i \% 4, j \% 4) \text{ equal to } (0,2) \text{ or } (i \% 4, j \% 4) \text{ equal to } (2,0), \\ v_{m5} & \text{otherwise;} \end{cases} \quad (8-316)$$

where the first and second subscripts of v are row and column indices, respectively, of the matrix specified as:

$$v = \begin{bmatrix} 20 & 18 & 32 & 19 & 25 & 24 \\ 22 & 19 & 35 & 21 & 28 & 26 \\ 26 & 23 & 42 & 24 & 33 & 31 \\ 28 & 25 & 45 & 26 & 35 & 33 \\ 32 & 28 & 51 & 30 & 40 & 38 \\ 36 & 32 & 58 & 34 & 46 & 43 \end{bmatrix}. \quad (8-317)$$

8.5.8 Scaling and transformation process for luma DC transform coefficients for Intra_16x16 macroblock type

Inputs to this process are transform coefficient level values for luma DC transform coefficients of Intra_16x16 macroblocks as a 4x4 array c with elements c_{ij} , where i and j form a two-dimensional frequency index.

Outputs of this process are 16 scaled DC values for luma 4x4 blocks of Intra_16x16 macroblocks as a 4x4 array dcY with elements dcY_{ij} .

Depending on the values of $\text{qpprime_y_zero_transform_bypass_flag}$ and QP'_Y , the following applies.

- If $\text{qpprime_y_zero_transform_bypass_flag}$ is equal to 1 and QP'_Y is equal to 0, the output dcY is derived as

$$\text{dcY}_{ij} = c_{ij} \text{ with } i, j = 0..3 \quad (8-318)$$

- Otherwise ($\text{qpprime_y_zero_transform_bypass_flag}$ is equal to 0 or QP'_Y is not equal to 0), the following text of this process specifies the output.

The inverse transform for the 4x4 luma DC transform coefficients is specified by:

$$f = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & -1 & 1 \\ 1 & -1 & 1 & -1 \end{bmatrix} \begin{bmatrix} c_{00} & c_{01} & c_{02} & c_{03} \\ c_{10} & c_{11} & c_{12} & c_{13} \\ c_{20} & c_{21} & c_{22} & c_{23} \\ c_{30} & c_{31} & c_{32} & c_{33} \end{bmatrix} \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & -1 & 1 \\ 1 & -1 & 1 & -1 \end{bmatrix}. \quad (8-319)$$

The bitstream shall not contain data that results in any element f_{ij} of f with $i, j = 0..3$ that exceeds the range of integer values from $-2^{(7 + \text{BitDepth}_Y)}$ to $2^{(7 + \text{BitDepth}_Y)} - 1$, inclusive.

After the inverse transform, scaling is performed as follows.

- If QP'_Y is greater than or equal to 36, the scaled result is derived as

$$dcY_{ij} = (f_{ij} * \text{LevelScale}(QP'_Y \% 6, 0, 0)) << (QP'_Y / 6 - 6), \quad \text{with } i, j = 0..3 \quad (8-320)$$

- Otherwise (QP'_Y is less than 36), the scaled result is derived as

$$dcY_{ij} = (f_{ij} * \text{LevelScale}(QP'_Y \% 6, 0, 0) + 2^{5 - QP'_Y / 6}) >> (6 - QP'_Y / 6), \quad \text{with } i, j = 0..3 \quad (8-321)$$

The bitstream shall not contain data that results in any element dcY_{ij} of dcY with $i, j = 0..3$ that exceeds the range of integer values from $-2^{(7 + \text{BitDepth}_Y)}$ to $2^{(7 + \text{BitDepth}_Y)} - 1$, inclusive.

NOTE 1 – When `entropy_coding_mode_flag` is equal to 0 and QP'_Y is less than 10 and `profile_idc` is equal to 66, 77, or 88, the range of values that can be represented for the elements c_{ij} of c is not sufficient to represent the full range of values of the elements dcY_{ij} of dcY that could be necessary to form a close approximation of the content of any possible source picture by use of the `Intra_16x16` macroblock type.

NOTE 2 – Since the range limit imposed on the elements dcY_{ij} of dcY is imposed after the right shift in Equation 8-321, a larger range of values must be supported in the decoder prior to the right shift.

8.5.9 Scaling and transformation process for chroma DC transform coefficients

Inputs to this process are transform coefficient level values for chroma DC transform coefficients of one chroma component of the macroblock as an $(\text{MbWidthC} / 4) \times (\text{MbHeightC} / 4)$ array c with elements c_{ij} , where i and j form a two-dimensional frequency index.

Outputs of this process are the scaled DC values as an $(\text{MbWidthC} / 4) \times (\text{MbHeightC} / 4)$ array dcC with elements dcC_{ij} .

Depending on the values of `qpprime_y_zero_transform_bypass_flag` and QP'_Y , the following applies.

- If `qpprime_y_zero_transform_bypass_flag` is equal to 1 and QP'_Y is equal to 0, the output dcC is derived as

$$dcC_{ij} = c_{ij} \quad \text{with } i = 0..(\text{MbWidthC} / 4) - 1 \text{ and } j = 0..(\text{MbHeightC} / 4) - 1. \quad (8-322)$$

- Otherwise (`qpprime_y_zero_transform_bypass_flag` is equal to 0 or QP'_Y is not equal to 0), the following text of this process specifies the output.

Depending on the variable `chroma_format_idc`, the inverse transform is specified as follows.

- If `chroma_format_idc` is equal to 1, the inverse transform for the 2x2 chroma DC transform coefficients is specified as

$$f = \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} c_{00} & c_{01} \\ c_{10} & c_{11} \end{bmatrix} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \quad (8-323)$$

- Otherwise, if `chroma_format_idc` is equal to 2, the inverse transform for the 2x4 chroma DC transform coefficients is specified as

$$f = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & -1 & 1 \\ 1 & -1 & 1 & -1 \end{bmatrix} \begin{bmatrix} c_{00} & c_{01} \\ c_{10} & c_{11} \\ c_{20} & c_{21} \\ c_{30} & c_{31} \end{bmatrix} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \quad (8-324)$$

- Otherwise (chroma_format_idc is equal to 3), the inverse transform for the 4x4 chroma DC transform coefficients is specified as follows.
 - If residual_colour_transform_flag is equal to 1 and the current macroblock prediction mode MbPartPredMode(mb_type, 0) is Intra_4x4 or Intra_8x8, the inverse transform for the 4x4 chroma DC transform coefficients is specified as

$$f_{ij} = c_{ij} \ll 2 \text{ with } i, j = 0..3 \quad (8-325)$$

- Otherwise, the inverse transform for the 4x4 chroma DC transform coefficients is specified as

$$f = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & -1 & 1 \\ 1 & -1 & 1 & -1 \end{bmatrix} \begin{bmatrix} c_{00} & c_{01} & c_{02} & c_{03} \\ c_{10} & c_{11} & c_{12} & c_{13} \\ c_{20} & c_{21} & c_{22} & c_{23} \\ c_{30} & c_{31} & c_{32} & c_{33} \end{bmatrix} \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & -1 & 1 \\ 1 & -1 & 1 & -1 \end{bmatrix} \quad (8-326)$$

The bitstream shall not contain data that results in any element f_{ij} of f with $i, j = 0..3$ that exceeds the range of integer values from $-2^{(7 + \text{BitDepth}_C)}$ to $2^{(7 + \text{BitDepth}_C)} - 1$, inclusive.

After the inverse transform, scaling is performed depending on the variable chroma_format_idc as follows.

- If chroma_format_idc is equal to 1, the scaled result is derived as

$$dcC_{ij} = ((f_{ij} * \text{LevelScale}(QP'_C \% 6, 0, 0)) \ll (QP'_C / 6)) \gg 5, \text{ with } i, j = 0, 1 \quad (8-327)$$

- If chroma_format_idc is equal to 2, the following applies.

- The variable $QP'_{C,DC}$ is derived as

$$QP'_{C,DC} = QP'_C + 3 \quad (8-328)$$

- Depending on the value of $QP'_{C,DC}$, the following applies.

- If $QP'_{C,DC}$ is greater than or equal to 36, the scaled result is derived as

$$dcC_{ij} = (f_{ij} * \text{LevelScale}(QP'_{C,DC} \% 6, 0, 0)) \ll (QP'_{C,DC} / 6 - 6), \text{ with } i = 0..3, j = 0, 1 \quad (8-329)$$

- Otherwise ($QP'_{C,DC}$ is less than 36), the scaled result is derived as

$$dcC_{ij} = (f_{ij} * \text{LevelScale}(QP'_{C,DC} \% 6, 0, 0) + 2^{5-QP'_{C,DC}/6}) \gg (6 - QP'_{C,DC} / 6), \text{ with } i = 0..3, j = 0, 1 \quad (8-330)$$

- Otherwise (chroma_format_idc is equal to 3), the following applies.

- If QP'_C is greater than or equal to 36, the scaled result is derived as

$$dcC_{ij} = (f_{ij} * \text{LevelScale}(QP'_C \% 6, 0, 0)) \ll (QP'_C / 6 - 6), \text{ with } i, j = 0..3. \quad (8-331)$$

- Otherwise (QP'_C is less than 36), the scaled result is derived as

$$dcC_{ij} = (f_{ij} * \text{LevelScale}(QP'_C \% 6, 0, 0) + 2^{5-QP'_C/6}) \gg (6 - QP'_C / 6), \text{ with } i, j = 0..3 \quad (8-332)$$

The bitstream shall not contain data that results in any element dcC_{ij} of dcC with $i, j = 0..3$ that exceeds the range of integer values from $-2^{(7 + \text{BitDepth}_C)}$ to $2^{(7 + \text{BitDepth}_C)} - 1$, inclusive.

NOTE 1 – When entropy_coding_mode_flag is equal to 0 and QP'_C is less than 4 and profile_idc is equal to 66, 77, or 88, the range of values that can be represented for the elements c_{ij} of c may not be sufficient to represent the full range of values of the elements dcC_{ij} of dcC that could be necessary to form a close approximation of the content of any possible source picture.

NOTE 2 – Since the range limit imposed on the elements dcC_{ij} of dcC is imposed after the right shift in Equation 8-327, 8-330, or 8-332, a larger range of values must be supported in the decoder prior to the right shift.

8.5.10 Scaling and transformation process for residual 4x4 blocks

Input to this process is a 4x4 array c with elements c_{ij} which is either an array relating to a residual block of the luma component or an array relating to a residual block of a chroma component.

Outputs of this process are residual sample values as 4x4 array r with elements r_{ij} .

Depending on the values of $qpprime_y_zero_transform_bypass_flag$ and QP'_Y , the following applies.

- If $qpprime_y_zero_transform_bypass_flag$ is equal to 1 and QP'_Y is equal to 0, the output r is derived as

$$r_{ij} = c_{ij} \text{ with } i, j = 0..3 \quad (8-333)$$

- Otherwise ($qpprime_y_zero_transform_bypass_flag$ is equal to 0 or QP'_Y is not equal to 0), the following text of this process specifies the output.

The variable $bitDepth$ is derived as follows.

- If the input array c relates to a luma residual block, $bitDepth$ is set equal to $BitDepth_Y$.
- Otherwise (the input array c relates to a chroma residual block), $bitDepth$ is set equal to $BitDepth'_C$.

The bitstream shall not contain data that results in any element c_{ij} of c with $i, j = 0..3$ that exceeds the range of integer values from $-2^{(7 + bitDepth)}$ to $2^{(7 + bitDepth)} - 1$, inclusive.

The variable $sMbFlag$ is derived as follows.

- If mb_type is equal to SI or the macroblock prediction mode is equal to Inter in an SP slice, $sMbFlag$ is set equal to 1,
- Otherwise (mb_type not equal to SI and the macroblock prediction mode is not equal to Inter in an SP slice), $sMbFlag$ is set equal to 0.

The variable qP is derived as follows.

- If the input array c relates to a luma residual block and $sMbFlag$ is equal to 0

$$qP = QP'_Y \quad (8-334)$$

- Otherwise, if the input array c relates to a luma residual block and $sMbFlag$ is equal to 1

$$qP = QS_Y \quad (8-335)$$

- Otherwise, if the input array c relates to a chroma residual block and $sMbFlag$ is equal to 0

$$qP = QP'_C \quad (8-336)$$

- Otherwise (the input array c relates to a chroma residual block and $sMbFlag$ is equal to 1),

$$qP = QS_C \quad (8-337)$$

Scaling of 4x4 block transform coefficient levels c_{ij} proceeds as follows.

- If all of the following conditions are true
 - i is equal to 0
 - j is equal to 0
 - c relates to a luma residual block coded using Intra_16x16 prediction mode or c relates to a chroma residual block

the variable d_{00} is derived by

$$d_{00} = c_{00} \quad (8-338)$$

– Otherwise, the following applies.

– If qP is greater than or equal to 24, the scaled result is derived as follows

$$d_{ij} = (c_{ij} * \text{LevelScale}(qP \% 6, i, j)) \ll (qP / 6 - 4), \text{ with } i, j = 0..3 \text{ except as noted above} \quad (8-339)$$

– Otherwise (qP is less than 24), the scaled result is derived as follows

$$d_{ij} = (c_{ij} * \text{LevelScale}(qP \% 6, i, j) + 2^{3-qP/6}) \gg (4 - qP / 6), \text{ with } i, j = 0..3 \text{ except as noted above} \quad (8-340)$$

The bitstream shall not contain data that results in any element d_{ij} of d with $i, j = 0..3$ that exceeds the range of integer values from $-2^{(7 + \text{bitDepth})}$ to $2^{(7 + \text{bitDepth})} - 1$, inclusive.

The transform process shall convert the block of scaled transform coefficients to a block of output samples in a manner mathematically equivalent to the following.

First, each (horizontal) row of scaled transform coefficients is transformed using a one-dimensional inverse transform as follows.

A set of intermediate values is computed as follows.

$$e_{i0} = d_{i0} + d_{i2}, \text{ with } i = 0..3 \quad (8-341)$$

$$e_{i1} = d_{i0} - d_{i2}, \text{ with } i = 0..3 \quad (8-342)$$

$$e_{i2} = (d_{i1} \gg 1) - d_{i3}, \text{ with } i = 0..3 \quad (8-343)$$

$$e_{i3} = d_{i1} + (d_{i3} \gg 1), \text{ with } i = 0..3 \quad (8-344)$$

The bitstream shall not contain data that results in any element e_{ij} of e with $i, j = 0..3$ that exceeds the range of integer values from $-2^{(7 + \text{bitDepth})}$ to $2^{(7 + \text{bitDepth})} - 1$, inclusive.

Then, the transformed result is computed from these intermediate values as follows.

$$f_{i0} = e_{i0} + e_{i3}, \text{ with } i = 0..3 \quad (8-345)$$

$$f_{i1} = e_{i1} + e_{i2}, \text{ with } i = 0..3 \quad (8-346)$$

$$f_{i2} = e_{i1} - e_{i2}, \text{ with } i = 0..3 \quad (8-347)$$

$$f_{i3} = e_{i0} - e_{i3}, \text{ with } i = 0..3 \quad (8-348)$$

The bitstream shall not contain data that results in any element f_{ij} of f with $i, j = 0..3$ that exceeds the range of integer values from $-2^{(7 + \text{bitDepth})}$ to $2^{(7 + \text{bitDepth})} - 1$, inclusive.

Then, each (vertical) column of the resulting matrix is transformed using the same one-dimensional inverse transform as follows.

A set of intermediate values is computed as follows.

$$g_{0j} = f_{0j} + f_{2j}, \text{ with } j = 0..3 \quad (8-349)$$

$$g_{1j} = f_{0j} - f_{2j}, \text{ with } j = 0..3 \quad (8-350)$$

$$g_{2j} = (f_{1j} \gg 1) - f_{3j}, \text{ with } j = 0..3 \quad (8-351)$$

$$g_{3j} = f_{1j} + (f_{3j} \gg 1), \text{ with } j = 0..3 \quad (8-352)$$

The bitstream shall not contain data that results in any element g_{ij} of g with $i, j = 0..3$ that exceeds the range of integer values from $-2^{(7 + \text{bitDepth})}$ to $2^{(7 + \text{bitDepth})} - 1$, inclusive.

Then, the transformed result is computed from these intermediate values as follows.

$$h_{0j} = g_{0j} + g_{3j}, \text{ with } j = 0..3 \quad (8-353)$$

$$h_{1j} = g_{1j} + g_{2j}, \text{ with } j = 0..3 \quad (8-354)$$

$$h_{2j} = g_{1j} - g_{2j}, \text{ with } j = 0..3 \quad (8-355)$$

$$h_{3j} = g_{0j} - g_{3j}, \text{ with } j = 0..3 \quad (8-356)$$

The bitstream shall not contain data that results in any element h_{ij} of h with $i, j = 0..3$ that exceeds the range of integer values from $-2^{(7 + \text{bitDepth})}$ to $2^{(7 + \text{bitDepth})} - 33$, inclusive.

After performing both the one-dimensional horizontal and the one-dimensional vertical inverse transforms to produce an array of transformed samples, the final constructed residual sample values is derived as

$$r_{ij} = (h_{ij} + 2^5) \gg 6 \text{ with } i, j = 0..3 \quad (8-357)$$

8.5.11 Scaling and transformation process for residual 8x8 luma blocks

Input to this process is an 8x8 array c with elements c_{ij} which is an array relating to an 8x8 residual block of the luma component.

Outputs of this process are residual sample values as 8x8 array r with elements r_{ij} .

Depending on the values of `qpprime_y_zero_transform_bypass_flag` and QP'_Y , the following applies.

- If `qpprime_y_zero_transform_bypass_flag` is equal to 1 and QP'_Y is equal to 0, the output r is derived as

$$r_{ij} = c_{ij} \text{ with } i, j = 0..7 \quad (8-358)$$

- Otherwise (`qpprime_y_zero_transform_bypass_flag` is equal to 0 or QP'_Y is not equal to 0), the following text of this process specifies the output.

The bitstream shall not contain data that results in any element c_{ij} of c with $i, j = 0..7$ that exceeds the range of integer values from $-2^{(7 + \text{BitDepth}_Y)}$ to $2^{(7 + \text{BitDepth}_Y)} - 1$, inclusive.

The scaling process for 8x8 block transform coefficient levels c_{ij} proceeds as follows.

- If QP'_Y is greater than or equal to 36, the scaled result is derived as

$$d_{ij} = (c_{ij} * \text{LevelScale8x8}(QP'_Y \% 6, i, j)) \ll (QP'_Y / 6 - 6), \text{ with } i, j = 0..7 \quad (8-359)$$

- Otherwise (QP'_Y is less than 36), the scaled result is derived as

$$d_{ij} = (c_{ij} * \text{LevelScale8x8}(QP'_Y \% 6, i, j)) + 2^{5-QP'_Y/6} \gg (6 - QP'_Y/6), \text{ with } i, j = 0..7 \quad (8-360)$$

The bitstream shall not contain data that results in any element d_{ij} of d with $i, j = 0..7$ that exceeds the range of integer values from $-2^{(7 + \text{BitDepth}_Y)}$ to $2^{(7 + \text{BitDepth}_Y)} - 1$, inclusive.

The transform process shall convert the block of scaled transform coefficients to a block of output samples in a manner mathematically equivalent to the following.

First, each (horizontal) row of scaled transform coefficients is transformed using a one-dimensional inverse transform as follows.

- A set of intermediate values e_{ij} is derived by

$$e_{i0} = d_{i0} + d_{i4}, \text{ with } i = 0..7 \quad (8-361)$$

$$e_{i1} = -d_{i3} + d_{i5} - d_{i7} - (d_{i7} \gg 1), \text{ with } i = 0..7 \quad (8-362)$$

$$e_{i2} = d_{i0} - d_{i4}, \text{ with } i = 0..7 \quad (8-363)$$

$$e_{i3} = d_{i1} + d_{i7} - d_{i3} - (d_{i3} \gg 1), \text{ with } i = 0..7 \quad (8-364)$$

$$e_{i4} = (d_{i2} \gg 1) - d_{i6}, \text{ with } i = 0..7 \quad (8-365)$$

$$e_{i5} = -d_{i1} + d_{i7} + d_{i5} + (d_{i5} \gg 1), \text{ with } i = 0..7 \quad (8-366)$$

$$e_{i6} = d_{i2} + (d_{i6} \gg 1), \text{ with } i = 0..7 \quad (8-367)$$

$$e_{i7} = d_{i3} + d_{i5} + d_{i1} + (d_{i1} \gg 1), \text{ with } i = 0..7 \quad (8-368)$$

- A second set of intermediate results f_{ij} is computed from the intermediate values e_{ij} as

$$f_{i0} = e_{i0} + e_{i6}, \text{ with } i = 0..7 \quad (8-369)$$

$$f_{i1} = e_{i1} + (e_{i7} \gg 2), \text{ with } i = 0..7 \quad (8-370)$$

$$f_{i2} = e_{i2} + e_{i4}, \text{ with } i = 0..7 \quad (8-371)$$

$$f_{i3} = e_{i3} + (e_{i5} \gg 2), \text{ with } i = 0..7 \quad (8-372)$$

$$f_{i4} = e_{i2} - e_{i4}, \text{ with } i = 0..7 \quad (8-373)$$

$$f_{i5} = (e_{i3} \gg 2) - e_{i5}, \text{ with } i = 0..7 \quad (8-374)$$

$$f_{i6} = e_{i0} - e_{i6}, \text{ with } i = 0..7 \quad (8-375)$$

$$f_{i7} = e_{i7} - (e_{i1} \gg 2), \text{ with } i = 0..7 \quad (8-376)$$

- Then, the transformed result g_{ij} is computed from these intermediate values f_{ij} as

$$g_{i0} = f_{i0} + f_{i7}, \text{ with } i = 0..7 \quad (8-377)$$

$$g_{i1} = f_{i2} + f_{i5}, \text{ with } i = 0..7 \quad (8-378)$$

$$g_{i2} = f_{i4} + f_{i3}, \text{ with } i = 0..7 \quad (8-379)$$

$$g_{i3} = f_{i6} + f_{i1}, \text{ with } i = 0..7 \quad (8-380)$$

$$g_{i4} = f_{i6} - f_{i1}, \text{ with } i = 0..7 \quad (8-381)$$

$$g_{i5} = f_{i4} - f_{i3}, \text{ with } i = 0..7 \quad (8-382)$$

$$g_{i6} = f_{i2} - f_{i5}, \text{ with } i = 0..7 \quad (8-383)$$

$$g_{i7} = f_{i0} - f_{i7}, \text{ with } i = 0..7 \quad (8-384)$$

Then, each (vertical) column of the resulting matrix is transformed using the same one-dimensional inverse transform as follows.

- A set of intermediate values h_{ij} is computed from the horizontally transformed value g_{ij} as

$$h_{0j} = g_{0j} + g_{4j}, \text{ with } j = 0..7 \quad (8-385)$$

$$h_{1j} = -g_{3j} + g_{5j} - g_{7j} - (g_{7j} >> 1), \text{ with } j = 0..7 \quad (8-386)$$

$$h_{2j} = g_{0j} - g_{4j}, \text{ with } j = 0..7 \quad (8-387)$$

$$h_{3j} = g_{1j} + g_{7j} - g_{3j} - (g_{3j} >> 1), \text{ with } j = 0..7 \quad (8-388)$$

$$h_{4j} = (g_{2j} >> 1) - g_{6j}, \text{ with } j = 0..7 \quad (8-389)$$

$$h_{5j} = -g_{1j} + g_{7j} + g_{5j} + (g_{5j} >> 1), \text{ with } j = 0..7 \quad (8-390)$$

$$h_{6j} = g_{2j} + (g_{6j} >> 1), \text{ with } j = 0..7 \quad (8-391)$$

$$h_{7j} = g_{3j} + g_{5j} + g_{1j} + (g_{1j} >> 1), \text{ with } j = 0..7 \quad (8-392)$$

- A second set of intermediate results k_{ij} is computed from the intermediate values h_{ij} as

$$k_{0j} = h_{0j} + h_{6j}, \text{ with } j = 0..7 \quad (8-393)$$

$$k_{1j} = h_{1j} + (h_{7j} >> 2), \text{ with } j = 0..7 \quad (8-394)$$

$$k_{2j} = h_{2j} + h_{4j}, \text{ with } j = 0..7 \quad (8-395)$$

$$k_{3j} = h_{3j} + (h_{5j} >> 2), \text{ with } j = 0..7 \quad (8-396)$$

$$k_{4j} = h_{2j} - h_{4j}, \text{ with } j = 0..7 \quad (8-397)$$

$$k_{5j} = (h_{3j} >> 2) - h_{5j}, \text{ with } j = 0..7 \quad (8-398)$$

$$k_{6j} = h_{0j} - h_{6j}, \text{ with } j = 0..7 \quad (8-399)$$

$$k_{7j} = h_{7j} - (h_{1j} \gg 2), \text{ with } j = 0..7 \quad (8-400)$$

- Then, the transformed result m_{ij} is computed from these intermediate values k_{ij} as

$$m_{0j} = k_{0j} + k_{7j}, \text{ with } j = 0..7 \quad (8-401)$$

$$m_{1j} = k_{2j} + k_{5j}, \text{ with } j = 0..7 \quad (8-402)$$

$$m_{2j} = k_{4j} + k_{3j}, \text{ with } j = 0..7 \quad (8-403)$$

$$m_{3j} = k_{6j} + k_{1j}, \text{ with } j = 0..7 \quad (8-404)$$

$$m_{4j} = k_{6j} - k_{1j}, \text{ with } j = 0..7 \quad (8-405)$$

$$m_{5j} = k_{4j} - k_{3j}, \text{ with } j = 0..7 \quad (8-406)$$

$$m_{6j} = k_{2j} - k_{5j}, \text{ with } j = 0..7 \quad (8-407)$$

$$m_{7j} = k_{0j} - k_{7j}, \text{ with } j = 0..7 \quad (8-408)$$

The bitstream shall not contain data that results in any element e_{ij} , f_{ij} , g_{ij} , h_{ij} , or k_{ij} for i and j in the range of $0..7$, inclusive, that exceeds the range of integer values from $-2^{(7 + \text{BitDepth}_Y)}$ to $2^{(7 + \text{BitDepth}_Y)} - 1$, inclusive.

The bitstream shall not contain data that results in any element m_{ij} for i and j in the range of $0..7$, inclusive, that exceeds the range of integer values from $-2^{(7 + \text{BitDepth}_Y)}$ to $2^{(7 + \text{BitDepth}_Y)} - 33$, inclusive.

After performing both the one-dimensional horizontal and the one-dimensional vertical inverse transforms to produce an array of transformed samples, the final constructed residual sample values are derived as

$$r_{ij} = (m_{ij} + 2^5) \gg 6 \text{ with } i, j = 0..7 \quad (8-409)$$

8.5.12 Picture construction process prior to deblocking filter process

Inputs to this process are

- luma4x4BlkIdx or chroma4x4BlkIdx or luma8x8BlkIdx
- a sample array u with elements u_{ij} which is either a 4x4 luma block or a 4x4 chroma block or an 8x8 luma block

The position of the upper-left luma sample of the current macroblock is derived by invoking the inverse macroblock scanning process in subclause 6.4.1 with CurrMbAddr as input and the output being assigned to (xP, yP) .

When u is a luma block, for each sample u_{ij} of the luma block, the following applies.

- Depending on the size of the block u , the following applies.
 - If u is an 4x4 luma block, the position of the upper-left sample of the 4x4 luma block with index luma4x4BlkIdx inside the macroblock is derived by invoking the inverse 4x4 luma block scanning process in subclause 6.4.3 with luma4x4BlkIdx as the input and the output being assigned to (xO, yO) , and the variable nE is set equal to 4.
 - Otherwise (u is an 8x8 luma block), the position of the upper-left sample of the 8x8 luma block with index luma8x8BlkIdx inside the macroblock is derived by invoking the inverse 8x8 luma block scanning process in subclause 6.4.4 with luma8x8BlkIdx as the input and the output being assigned to (xO, yO) , and the variable nE is set equal to 8.
- Depending on the variable MbaffFrameFlag and the current macroblock, the following applies.
 - If MbaffFrameFlag is equal to 1 and the current macroblock is a field macroblock

$$S'_L[xP + xO + j, yP + 2 * (yO + i)] = u_{ij} \text{ with } i, j = 0..nE - 1 \quad (8-410)$$

- Otherwise (MbaffFrameFlag is equal to 0 or the current macroblock is a frame macroblock),

$$S'_L[xP + xO + j, yP + yO + i] = u_{ij} \quad \text{with } i, j = 0..nE - 1 \quad (8-411)$$

When u is a chroma block, for each sample u_{ij} of the 4x4 chroma block, the following applies.

- The subscript C in the variable S'_C is replaced with Cb for the Cb chroma component and with Cr for the Cr chroma component.
- Depending on the variable chroma_format_idc, the position of the upper-left sample of a 4x4 chroma block with index chroma4x4BlkIdx inside the macroblock is derived as follows.

- If chroma_format_idc is equal to 1 or 2, the following applies.

$$xO = \text{InverseRasterScan}(\text{chroma4x4BlkIdx}, 4, 4, 8, 0) \quad (8-412)$$

$$yO = \text{InverseRasterScan}(\text{chroma4x4BlkIdx}, 4, 4, 8, 1) \quad (8-413)$$

- Otherwise (chroma_format_idc is equal to 3), the following applies.

$$xO = \text{InverseRasterScan}(\text{chroma4x4BlkIdx} / 4, 8, 8, 16, 0) + \text{InverseRasterScan}(\text{chroma4x4BlkIdx} \% 4, 4, 4, 8, 0) \quad (8-414)$$

$$yO = \text{InverseRasterScan}(\text{chroma4x4BlkIdx} / 4, 8, 8, 16, 1) + \text{InverseRasterScan}(\text{chroma4x4BlkIdx} \% 4, 4, 4, 8, 1) \quad (8-415)$$

- Depending on the variable MbaffFrameFlag and the current macroblock, the following applies.

- If MbaffFrameFlag is equal to 1 and the current macroblock is a field macroblock

$$S'_C[(xP / \text{subWidthC}) + xO + j, ((yP + \text{SubHeightC} - 1) / \text{SubHeightC}) + 2 * (yO + i)] = u_{ij} \quad \text{with } i, j = 0..3 \quad (8-416)$$

- Otherwise (MbaffFrameFlag is equal to 0 or the current macroblock is a frame macroblock),

$$S'_C[(xP / \text{subWidthC}) + xO + j, (yP / \text{SubHeightC}) + yO + i] = u_{ij} \quad \text{with } i, j = 0..3 \quad (8-417)$$

8.5.13 Residual colour transform process

This process is invoked when residual_colour_transform_flag is equal to 1.

After invoking, this process is suspended until the derivation of $R_{Y,ij}$, $R_{Cb,ij}$, and $R_{Cr,ij}$ has been completed for $i, j = 0..ijMax$, where $ijMax$ is specified as follows.

- If transform_size_8x8_flag is equal to 0, the variable $ijMax$ is set equal to 3.
- Otherwise (transform_size_8x8_flag is equal to 1), the variable $ijMax$ is set equal to 7.

At the resumption of this process, all values $R_{Y,ij}$, $R_{Cb,ij}$, and $R_{Cr,ij}$ with $i, j = 0..ijMax$ shall be available through prior invocations of the relevant processes specified in subclauses 8.5.1, 8.5.2, 8.5.3, or 8.5.4

For each $i, j = 0..ijMax$, the residual colour transform is computed as

$$t = R_{Y,ij} - (R_{Cb,ij} >> 1) \quad (8-418)$$

$$R_{G,ij} = t + R_{Cb,ij} \quad (8-419)$$

$$R_{B,ij} = t - (R_{Cr,ij} >> 1) \quad (8-420)$$

$$R_{R,ij} = R_{B,ij} + R_{Cr,ij} \quad (8-421)$$

NOTE – The residual colour transform is similar to the YCgCo transformation specified in Equations E-30 through E-33. However, the residual colour transform operates on the decoded residual difference data within the decoding process rather than operating as a post-processing step that is outside the decoding process specified in this Recommendation | International Standard.

8.6 Decoding process for P macroblocks in SP slices or SI macroblocks

This process is invoked when decoding P macroblock types in an SP slice type or an SI macroblock type in SI slices.

Inputs to this process are the prediction residual transform coefficient levels and the predicted samples for the current macroblock.

Outputs of this process are the decoded samples of the current macroblock prior to the deblocking filter process.

This subclause specifies the transform coefficient decoding process and picture construction process for P macroblock types in SP slices and SI macroblock type in SI slices.

NOTE – SP slices make use of Inter predictive coding to exploit temporal redundancy in the sequence, in a similar manner to P slice coding. Unlike P slice coding, however, SP slice coding allows identical reconstruction of a slice even when different reference pictures are being used. SI slices make use of spatial prediction, in a similar manner to I slices. SI slice coding allows identical reconstruction to a corresponding SP slice. The properties of SP and SI slices aid in providing functionalities for bitstream switching, splicing, random access, fast-forward, fast reverse, and error resilience/recovery.

An SP slice consists of macroblocks coded either as I macroblock types or P macroblock types.

An SI slice consists of macroblocks coded either as I macroblock types or SI macroblock type.

The transform coefficient decoding process and picture construction process prior to deblocking filter process for I macroblock types in SI slices is invoked as specified in subclause 8.5. SI macroblock type is decoded as described below.

When the current macroblock is coded as P_Skip, all values of LumaLevel, ChromaDCLevel, ChromaACLevel are set equal to 0 for the current macroblock.

8.6.1 SP decoding process for non-switching pictures

This process is invoked, when decoding P macroblock types in SP slices in which `sp_for_switch_flag` is equal to 0.

Inputs to this process are Inter prediction samples for the current macroblock from subclause 8.4 and the prediction residual transform coefficient levels.

Outputs of this process are the decoded samples of the current macroblock prior to the deblocking filter process.

This subclause applies to all macroblocks in SP slices in which `sp_for_switch_flag` is equal to 0, except those with macroblock prediction mode equal to `Intra_4x4` or `Intra_16x16`. It does not apply to SI slices.

8.6.1.1 Luma transform coefficient decoding process

Inputs to this process are Inter prediction luma samples for the current macroblock pred_L from subclause 8.4 and the prediction residual transform coefficient levels, LumaLevel, and the index of the 4x4 luma block `luma4x4BlkIdx`.

The position of the upper-left sample of the 4x4 luma block with index `luma4x4BlkIdx` inside the current macroblock is derived by invoking the inverse 4x4 luma block scanning process in subclause 6.4.3 with `luma4x4BlkIdx` as the input and the output being assigned to (x, y) .

Let the variable p be a 4x4 array of prediction samples with element p_{ij} being derived as follows.

$$p_{ij} = \text{pred}_L[x + j, y + i] \quad \text{with } i, j = 0..3 \quad (8-422)$$

The variable p is transformed producing transform coefficients c^p according to:

$$c^p = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 2 & 1 & -1 & -2 \\ 1 & -1 & -1 & 1 \\ 1 & -2 & 2 & -1 \end{bmatrix} \begin{bmatrix} p_{00} & p_{01} & p_{02} & p_{03} \\ p_{10} & p_{11} & p_{12} & p_{13} \\ p_{20} & p_{21} & p_{22} & p_{23} \\ p_{30} & p_{31} & p_{32} & p_{33} \end{bmatrix} \begin{bmatrix} 1 & 2 & 1 & 1 \\ 1 & 1 & -1 & -2 \\ 1 & -1 & -1 & 2 \\ 1 & -2 & 1 & -1 \end{bmatrix} \quad (8-423)$$

The inverse transform coefficient scanning process as described in subclause 8.5.5 is invoked with $\text{LumaLevel}[\text{ luma4x4BlkIdx }]$ as the input and the two-dimensional array c^r with elements c_{ij}^r as the output.

The prediction residual transform coefficients c^r are scaled using quantisation parameter QP_Y , and added to the transform coefficients of the prediction block c^p with $i, j = 0..3$ as follows.

$$c_{ij}^s = c_{ij}^p + (((c_{ij}^r * \text{LevelScale}(QP_Y \% 6, i, j) * A_{ij}) << (QP_Y / 6)) >> 10) \quad (8-424)$$

where $\text{LevelScale}(m, i, j)$ is specified in Equation 8-312, and where A_{ij} is specified as:

$$A_{ij} = \begin{cases} 16 & \text{for } (i, j) \in \{(0,0), (0,2), (2,0), (2,2)\}, \\ 25 & \text{for } (i, j) \in \{(1,1), (1,3), (3,1), (3,3)\}, \\ 20 & \text{otherwise;} \end{cases} \quad (8-425)$$

The function $\text{LevelScale2}(m, i, j)$, used in the formulas below, is specified as:

$$\text{LevelScale2}(m, i, j) = \begin{cases} w_{m0} & \text{for } (i, j) \in \{(0,0), (0,2), (2,0), (2,2)\}, \\ w_{m1} & \text{for } (i, j) \in \{(1,1), (1,3), (3,1), (3,3)\}, \\ w_{m2} & \text{otherwise;} \end{cases} \quad (8-426)$$

where the first and second subscripts of w are row and column indices, respectively, of the matrix specified as:

$$w = \begin{bmatrix} 13107 & 5243 & 8066 \\ 11916 & 4660 & 7490 \\ 10082 & 4194 & 6554 \\ 9362 & 3647 & 5825 \\ 8192 & 3355 & 5243 \\ 7282 & 2893 & 4559 \end{bmatrix} \quad (8-427)$$

The resulting sum, c^s , is quantised with a quantisation parameter QS_Y and with $i, j = 0..3$ as follows.

$$c_{ij} = \text{Sign}(c_{ij}^s) * ((\text{Abs}(c_{ij}^s) * \text{LevelScale2}(QS_Y \% 6, i, j) + (1 << (14 + QS_Y / 6))) >> (15 + QS_Y / 6)) \quad (8-428)$$

The scaling and transformation process for residual 4x4 blocks as specified in subclause 8.5.10 is invoked with c as the input and r as the output.

The 4x4 array u with elements u_{ij} is derived as follows.

$$u_{ij} = \text{Clip1}_Y(r_{ij}) \text{ with } i, j = 0..3 \quad (8-429)$$

The picture construction process prior to deblocking filter process in subclause 8.5.12 is invoked with luma4x4BlkIdx and u as the inputs.

8.6.1.2 Chroma transform coefficient decoding process

Inputs to this process are Inter prediction chroma samples for the current macroblock from subclause 8.4 and the prediction residual transform coefficient levels, ChromaDCLevel and ChromaACLevel .

This process is invoked twice: once for the Cb component and once for the Cr component. The component is referred to by replacing C with Cb for the Cb component and C with Cr for the Cr component. Let $iCbCr$ select the current chroma component.

For each 4x4 block of the current chroma component indexed using chroma4x4BlkIdx with chroma4x4BlkIdx equal to 0..3, the following applies.

- The position of the upper-left sample of a 4x4 chroma block with index chroma4x4BlkIdx inside the macroblock is derived as follows.

$$x = \text{InverseRasterScan}(\text{chroma4x4BlkIdx}, 4, 4, 8, 0) \quad (8-430)$$

$$y = \text{InverseRasterScan}(\text{chroma4x4BlkIdx}, 4, 4, 8, 1) \quad (8-431)$$

- Let p be a 4x4 array of prediction samples with elements p_{ij} being derived as follows.

$$p_{ij} = \text{pred}_c[x + j, y + i] \quad \text{with } i, j = 0..3 \quad (8-432)$$

- The 4x4 array p is transformed producing transform coefficients $c^p(\text{chroma4x4BlkIdx})$ using Equation 8-423.
- The variable chromaList , which is a list of 16 entries, is derived. $\text{chromaList}[0]$ is set equal to 0. $\text{chromaList}[k]$ with index $k = 1..15$ are specified as follows.

$$\text{chromaList}[k] = \text{ChromaACLevel}[\text{iCbCr}][\text{chroma4x4BlkIdx}][k - 1] \quad (8-433)$$

- The inverse transform coefficient scanning process as described in subclause 8.5.5 is invoked with chromaList as the input and the 4x4 array c^r as the output.
- The prediction residual transform coefficients c^r are scaled using quantisation parameter QP_C , and added to the transform coefficients of the prediction block c^p with $i, j = 0..3$ except for the combination $i = 0, j = 0$ as follows.

$$c_{ij}^s = c_{ij}^p(\text{chroma4x4BlkIdx}) + ((c_{ij}^r * \text{LevelScale}(QP_C \% 6, i, j) * A_{ij}) << (QP_C / 6)) >> 10) \quad (8-434)$$

- The resulting sum, c^s , is quantised with a quantisation parameter QS_C and with $i, j = 0..3$ except for the combination $i = 0, j = 0$ as follows. The derivation of $c_{00}(\text{chroma4x4BlkIdx})$ is described below in this subclause.

$$c_{ij}(\text{chroma4x4BlkIdx}) = (\text{Sign}(c_{ij}^s) * (\text{Abs}(c_{ij}^s) * \text{LevelScale2}(QS_C \% 6, i, j) + (1 << (14 + QS_C / 6)))) >> (15 + QS_C / 6) \quad (8-435)$$

- The scaling and transformation process for residual 4x4 blocks as specified in 8.5.10 is invoked with $c(\text{chroma4x4BlkIdx})$ as the input and r as the output.
- The 4x4 array u with elements u_{ij} is derived as follows.

$$u_{ij} = \text{Clip1}_c(r_{ij}) \quad \text{with } i, j = 0..3 \quad (8-436)$$

- The picture construction process prior to deblocking filter process in subclause 8.5.12 is invoked with chroma4x4BlkIdx and u as the inputs.

The derivation of the DC transform coefficient level $c_{00}(\text{chroma4x4BlkIdx})$ is specified as follows. The DC transform coefficients of the 4 prediction chroma 4x4 blocks of the current component of the macroblock are assembled into a 2x2 matrix with elements $c_{00}^p(\text{chroma4x4BlkIdx})$ and a 2x2 transform is applied to the DC transform coefficients as follows

$$dc^p = \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} c_{00}^p(0) & c_{00}^p(1) \\ c_{00}^p(2) & c_{00}^p(3) \end{bmatrix} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \quad (8-437)$$

The chroma DC prediction residual transform coefficient levels, $\text{ChromaDCLevel}[\text{iCbCr}][k]$ with $k = 0..3$ are scaled using quantisation parameter QP , and added to the prediction DC transform coefficients as follows.

$$dc_{ij}^s = dc_{ij}^p + ((\text{ChromaDCLevel}[\text{iCbCr}][j * 2 + i] * \text{LevelScale}(QP_C \% 6, 0, 0) * A_{00}) << (QP_C / 6)) >> 9) \quad \text{with } i, j = 0, 1 \quad (8-438)$$

The 2x2 array dc^s , is quantised using the quantisation parameter QS_C as follows.

$$dc_{ij}^r = (\text{Sign}(dc_{ij}^s) * (\text{Abs}(dc_{ij}^s) * \text{LevelScale2}(QS_C \% 6, 0, 0) + (1 << (15 + QS_C / 6)))) >> (16 + QS_C / 6) \quad \text{with } i, j = 0, 1 \quad (8-439)$$

The 2x2 array f with elements f_{ij} and $i, j = 0..1$ is derived as follows.

$$f = \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} dc_{00}^r & dc_{01}^r \\ dc_{10}^r & dc_{11}^r \end{bmatrix} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}. \quad (8-440)$$

Scaling of the elements f_{ij} of f is performed as follows.

$$c_{00}(j * 2 + i) = ((f_{ij} * \text{LevelScale}(QS_C \% 6, 0, 0)) \ll (QS_C / 6)) \gg 5 \text{ with } i, j = 0, 1 \quad (8-441)$$

8.6.2 SP and SI slice decoding process for switching pictures

This process is invoked, when decoding P macroblock types in SP slices in which `sp_for_switch_flag` is equal to 1 and when decoding SI macroblock type in SI slices.

Inputs to this process are the prediction residual transform coefficient levels and the prediction sample arrays pred_L , pred_{Cb} and pred_{Cr} for the current macroblock.

8.6.2.1 Luma transform coefficient decoding process

Inputs to this process are prediction luma samples pred_L and the luma prediction residual transform coefficient levels, `LumaLevel`.

The 4x4 array p with elements p_{ij} with $i, j = 0..3$ is derived as in subclause 8.6.1.1, is transformed according to Equation 8-423 to produce transform coefficients c^p . These transform coefficients are then quantised with the quantisation parameter QS_Y , as follows:

$$c_{ij}^s = \text{Sign}(c_{ij}^p) * ((\text{Abs}(c_{ij}^p) * \text{LevelScale2}(QS_Y \% 6, i, j) + (1 \ll (14 + QS_Y / 6))) \gg (15 + QS_Y / 6)) \text{ with } i, j = 0..3 \quad (8-442)$$

The inverse transform coefficient scanning process as described in subclause 8.5.5 is invoked with `LumaLevel[luma4x4BlkIdx]` as the input and the two-dimensional array c^r with elements c_{ij}^r as the output.

The 4x4 array c with elements c_{ij} with $i, j = 0..3$ is derived as follows.

$$c_{ij} = c_{ij}^r + c_{ij}^s \text{ with } i, j = 0..3 \quad (8-443)$$

The scaling and transformation process for residual 4x4 blocks as specified in subclause 8.5.10 is invoked with c as the input and r as the output.

The 4x4 array u with elements u_{ij} is derived as follows.

$$u_{ij} = \text{Clip1}_Y(r_{ij}) \text{ with } i, j = 0..3 \quad (8-444)$$

The picture construction process prior to deblocking filter process in subclause 8.5.12 is invoked with `luma4x4BlkIdx` and u as the inputs.

8.6.2.2 Chroma transform coefficient decoding process

Inputs to this process are predicted chroma samples for the current macroblock from subclause 8.4 and the prediction residual transform coefficient levels, `ChromaDCLevel` and `ChromaACLevel`.

This process is invoked twice: once for the Cb component and once for the Cr component. The component is referred to by replacing C with Cb for the Cb component and C with Cr for the Cr component. Let `iCbCr` select the current chroma component.

For each 4x4 block of the current chroma component indexed using `chroma4x4BlkIdx` with `chroma4x4BlkIdx` equal to 0..3, the following applies.

1. The 4x4 array p with elements p_{ij} with $i, j = 0..3$ is derived as in subclause 8.6.1.2, is transformed according to Equation 8-423 to produce transform coefficients $c^p(\text{chroma4x4BlkIdx})$. These transform coefficients are then quantised with the quantisation parameter QS_C , with $i, j = 0..3$ except for the combination $i = 0, j = 0$ as follows. The processing of $c_{00}^p(\text{chroma4x4BlkIdx})$ is described below in this subclause.

$$c_{ij}^s = (\text{Sign}(c_{ij}^p(\text{chroma4x4BlkIdx})) * (\text{Abs}(c_{ij}^p(\text{chroma4x4BlkIdx})) * \text{LevelScale2}(\text{QSC} \% 6, i, j) + (1 << (14 + \text{QSC} / 6)))) >> (15 + \text{QSC} / 6) \quad (8-445)$$

- The variable chromaList, which is a list of 16 entries, is derived. chromaList[0] is set equal to 0. chromaList[k] with index k = 1..15 are specified as follows.

$$\text{chromaList}[k] = \text{ChromaACLevel}[\text{iCbCr}][\text{chroma4x4BlkIdx}][k - 1] \quad (8-446)$$

- The inverse transform coefficient scanning process as described in subclause 8.5.5 is invoked with chromaList as the input and the two-dimensional array $c^r(\text{chroma4x4BlkIdx})$ with elements $c_{ij}^r(\text{chroma4x4BlkIdx})$ as the output.
- The 4x4 array $c(\text{chroma4x4BlkIdx})$ with elements $c_{ij}(\text{chroma4x4BlkIdx})$ with $i, j = 0..3$ except for the combination $i = 0, j = 0$ is derived as follows. The derivation of $c_{00}(\text{chroma4x4BlkIdx})$ is described below.

$$c_{ij}(\text{chroma4x4BlkIdx}) = c_{ij}^r(\text{chroma4x4BlkIdx}) + c_{ij}^s \quad (8-447)$$

- The scaling and transformation process for residual 4x4 blocks as specified in subclause 8.5.10 is invoked with $c(\text{chroma4x4BlkIdx})$ as the input and r as the output.
- The 4x4 array u with elements u_{ij} is derived as follows.

$$u_{ij} = \text{Clip1}_C(r_{ij}) \text{ with } i, j = 0..3 \quad (8-448)$$

- The picture construction process prior to deblocking filter process in subclause 8.5.12 is invoked with chroma4x4BlkIdx and u as the inputs.

The derivation of the DC transform coefficient level $c_{00}(\text{chroma4x4BlkIdx})$ is specified as follows. The DC transform coefficients of the 4 prediction 4x4 chroma blocks of the current component of the macroblock, $c_{00}^p(\text{chroma4x4BlkIdx})$, are assembled into a 2x2 matrix, and a 2x2 transform is applied to the DC transform coefficients of these blocks according to Equation 8-437 resulting in DC transform coefficients dc_{ij}^p .

These DC transform coefficients are then quantised with the quantisation parameter QSC , as given by:

$$dc_{ij}^s = (\text{Sign}(dc_{ij}^p) * (\text{Abs}(dc_{ij}^p) * \text{LevelScale2}(\text{QSC} \% 6, 0, 0) + (1 << (15 + \text{QSC} / 6)))) >> (16 + \text{QSC} / 6) \quad \text{with } i, j = 0, 1 \quad (8-449)$$

The parsed chroma DC prediction residual transform coefficients, $\text{ChromaDCLevel}[\text{iCbCr}][k]$ with $k = 0..3$ are added to these quantised DC transform coefficients of the prediction block, as given by:

$$dc_{ij}^r = dc_{ij}^s + \text{ChromaDCLevel}[\text{iCbCr}][j * 2 + i] \text{ with } i, j = 0, 1 \quad (8-450)$$

The 2x2 array f with elements f_{ij} and $i, j = 0..1$ is derived using Equation 8-440.

The 2x2 array f with elements f_{ij} and $i, j = 0..1$ is copied as follows.

$$c_{00}(j * 2 + i) = f_{ij} \text{ with } i, j = 0, 1 \quad (8-451)$$

8.7 Deblocking filter process

A conditional filtering process is applied to all NxN (where $N = 4$ or $N = 8$ for luma, and $N = 4$ for chroma) block edges of a picture, except edges at the boundary of the picture and any edges for which the deblocking filter process is disabled by `disable_deblocking_filter_idc`, as specified below. This filtering process is performed on a macroblock basis after the completion of the picture construction process prior to deblocking filter process (as specified in subclauses 8.5 and 8.6) for the entire decoded picture, with all macroblocks in a picture processed in order of increasing macroblock addresses.

NOTE 1 – Prior to the operation of the deblocking filter process for each macroblock, the deblocked samples of the macroblock or macroblock pair above (if any) and the macroblock or macroblock pair to the left (if any) of the current macroblock are always available because the deblocking filter process is performed after the completion of the picture construction process prior to deblocking filter process for the entire decoded picture. However, for purposes of determining which edges are to be filtered

when `disable_deblocking_filter_idc` is equal to 2, macroblocks in different slices are considered not available during specified steps of the operation of the deblocking filter process.

The deblocking filter process is invoked for the luma and chroma components separately. For each macroblock and each component, vertical edges are filtered first, starting with the edge on the left-hand side of the macroblock proceeding through the edges towards the right-hand side of the macroblock in their geometrical order, and then horizontal edges are filtered, starting with the edge on the top of the macroblock proceeding through the edges towards the bottom of the macroblock in their geometrical order. Figure 8-10 shows edges of a macroblock which can be interpreted as luma or chroma edges.

When interpreting the edges in Figure 8-10 as luma edges, depending on the `transform_size_8x8_flag`, the following applies.

- If `transform_size_8x8_flag` is equal to 0, both types, the solid bold and dashed bold luma edges are filtered.
- Otherwise (`transform_size_8x8_flag` is equal to 1), only the solid bold luma edges are filtered.

When interpreting the edges in Figure 8-10 as chroma edges, depending on `chroma_format_idc`, the following applies.

- If `chroma_format_idc` is equal to 1 (4:2:0 format), only the solid bold chroma edges are filtered.
- Otherwise, if `chroma_format_idc` is equal to 2 (4:2:2 format), the solid bold vertical chroma edges are filtered and both types, the solid bold and dashed bold horizontal chroma edges are filtered.
- Otherwise, if `chroma_format_idc` is equal to 3 (4:4:4 format), both types, the solid bold and dashed bold chroma edges are filtered.
- Otherwise (`chroma_format_idc` is equal to 0 (monochrome)), no chroma edges are filtered.

Figure 8-10 – Boundaries in a macroblock to be filtered

For the current macroblock address `CurrMbAddr` proceeding over values $0..PicSizeInMbs - 1$, the following applies.

1. The derivation process for neighbouring macroblocks specified in subclause 6.4.8.1 is invoked and the output is assigned to `mbAddrA` and `mbAddrB`.
2. The variables `fieldModeMbFlag`, `filterInternalEdgesFlag`, `filterLeftMbEdgeFlag` and `filterTopMbEdgeFlag` are derived as follows.
 - The variable `fieldModeMbFlag` is derived as follows.
 - If any of the following conditions is true, `fieldModeMbFlag` is set equal to 1.
 - `field_pic_flag` is equal to 1
 - `MbaffFrameFlag` is equal to 1 and the macroblock `CurrMbAddr` is a field macroblock
 - Otherwise, `fieldModeMbFlag` is set equal to 0.
 - The variable `filterInternalEdgesFlag` is derived as follows.

- If `disable_deblocking_filter_idc` for the slice that contains the macroblock `CurrMbAddr` is equal to 1, the variable `filterInternalEdgesFlag` is set equal to 0;
 - Otherwise (`disable_deblocking_filter_idc` for the slice that contains the macroblock `CurrMbAddr` is not equal to 1), the variable `filterInternalEdgesFlag` is set equal to 1.
 - The variable `filterLeftMbEdgeFlag` is derived as follows.
 - If any of the following conditions is true, the variable `filterLeftMbEdgeFlag` is set equal to 0.
 - `MbaffFrameFlag` is equal to 0 and `CurrMbAddr % PicWidthInMbs` is equal to 0.
 - `MbaffFrameFlag` is equal to 1 and $(CurrMbAddr \gg 1) \% PicWidthInMbs$ is equal to 0
 - `disable_deblocking_filter_idc` for the slice that contains the macroblock `CurrMbAddr` is equal to 1
 - `disable_deblocking_filter_idc` for the slice that contains the macroblock `CurrMbAddr` is equal to 2 and the macroblock `mbAddrA` is not available
 - Otherwise, the variable `filterLeftMbEdgeFlag` is set equal to 1.
 - The variable `filterTopMbEdgeFlag` is derived as follows.
 - If any of the following conditions is true, the variable `filterTopMbEdgeFlag` is set equal to 0.
 - `MbaffFrameFlag` is equal to 0 and `CurrMbAddr` is less than `PicWidthInMbs`.
 - `MbaffFrameFlag` is equal to 1, $(CurrMbAddr \gg 1)$ is less than `PicWidthInMbs`, and the macroblock `CurrMbAddr` is a field macroblock.
 - `MbaffFrameFlag` is equal to 1, $(CurrMbAddr \gg 1)$ is less than `PicWidthInMbs`, the macroblock `CurrMbAddr` is a frame macroblock, and `CurrMbAddr % 2` is equal to 0.
 - `disable_deblocking_filter_idc` for the slice that contains the macroblock `CurrMbAddr` is equal to 1
 - `disable_deblocking_filter_idc` for the slice that contains the macroblock `CurrMbAddr` is equal to 2 and the macroblock `mbAddrB` is not available
 - Otherwise, the variable `filterTopMbEdgeFlag` is set equal to 1.
3. Given the variables `fieldModeMbFlag`, `filterInternalEdgesFlag`, `filterLeftMbEdgeFlag` and `filterTopMbEdgeFlag` the deblocking filtering is controlled as follows.
- When `filterLeftMbEdgeFlag` is equal to 1, the filtering of the left vertical luma edge is specified as follows.
 - The process specified in subclause 8.7.1 is invoked with `chromaEdgeFlag` = 0, `verticalEdgeFlag` = 1, `fieldModeFilteringFlag` = `fieldModeMbFlag`, and $(xE_k, yE_k) = (0, k)$ with $k = 0..15$ as input and S'_L as output.
 - When `filterInternalEdgesFlag` is equal to 1, the filtering of the internal vertical luma edges is specified as follows.
 - When `transform_size_8x8_flag` is equal to 0, the process specified in subclause 8.7.1 is invoked with `chromaEdgeFlag` = 0, `verticalEdgeFlag` = 1, `fieldModeFilteringFlag` = `fieldModeMbFlag`, and $(xE_k, yE_k) = (4, k)$ with $k = 0..15$ as input and S'_L as output.
 - The process specified in subclause 8.7.1 is invoked with `chromaEdgeFlag` = 0, `verticalEdgeFlag` = 1, `fieldModeFilteringFlag` = `fieldModeMbFlag`, and $(xE_k, yE_k) = (8, k)$ with $k = 0..15$ as input and S'_L as output.
 - When `transform_size_8x8_flag` is equal to 0, the process specified in subclause 8.7.1 is invoked with `chromaEdgeFlag` = 0, `verticalEdgeFlag` = 1, `fieldModeFilteringFlag` = `fieldModeMbFlag`, and $(xE_k, yE_k) = (12, k)$ with $k = 0..15$ as input and S'_L as output.
 - When `filterTopMbEdgeFlag` is equal to 1, the filtering of the top horizontal luma edge is specified as follows.
 - If `MbaffFrameFlag` is equal to 1, $(CurrMbAddr \% 2)$ is equal to 0, `CurrMbAddr` is greater than or equal to $2 * PicWidthInMbs$, the macroblock `CurrMbAddr` is a frame macroblock, and the macroblock $(CurrMbAddr - 2 * PicWidthInMbs + 1)$ is a field macroblock, the following applies.
 - The process specified in subclause 8.7.1 is invoked with `chromaEdgeFlag` = 0, `verticalEdgeFlag` = 0, `fieldModeFilteringFlag` = 1, and $(xE_k, yE_k) = (k, 0)$ with $k = 0..15$ as input and S'_L as output.

- The process specified in subclause 8.7.1 is invoked with $\text{chromaEdgeFlag} = 0$, $\text{verticalEdgeFlag} = 0$, $\text{fieldModeFilteringFlag} = 1$, and $(xE_k, yE_k) = (k, 1)$ with $k = 0..15$ as input and S'_L as output.
 - Otherwise, the process specified in subclause 8.7.1 is invoked with $\text{chromaEdgeFlag} = 0$, $\text{verticalEdgeFlag} = 0$, $\text{fieldModeFilteringFlag} = \text{fieldModeMbFlag}$, and $(xE_k, yE_k) = (k, 0)$ with $k = 0..15$ as input and S'_L as output.
- When $\text{filterInternalEdgesFlag}$ is equal to 1, the filtering of the internal horizontal luma edges is specified as follows.
 - When $\text{transform_size_8x8_flag}$ is equal to 0, the process specified in subclause 8.7.1 is invoked with $\text{chromaEdgeFlag} = 0$, $\text{verticalEdgeFlag} = 0$, $\text{fieldModeFilteringFlag} = \text{fieldModeMbFlag}$, and $(xE_k, yE_k) = (k, 4)$ with $k = 0..15$ as input and S'_L as output.
 - The process specified in subclause 8.7.1 is invoked with $\text{chromaEdgeFlag} = 0$, $\text{verticalEdgeFlag} = 0$, $\text{fieldModeFilteringFlag} = \text{fieldModeMbFlag}$, and $(xE_k, yE_k) = (k, 8)$ with $k = 0..15$ as input and S'_L as output.
 - When $\text{transform_size_8x8_flag}$ is equal to 0, the process specified in subclause 8.7.1 is invoked with $\text{chromaEdgeFlag} = 0$, $\text{verticalEdgeFlag} = 0$, $\text{fieldModeFilteringFlag} = \text{fieldModeMbFlag}$, and $(xE_k, yE_k) = (k, 12)$ with $k = 0..15$ as input and S'_L as output.
- For the filtering of both chroma components with $iCbCr = 0$ for Cb and $iCbCr = 1$ for Cr, the following applies.
 - When $\text{filterLeftMbEdgeFlag}$ is equal to 1, the filtering of the left vertical chroma edge is specified as follows.
 - The process specified in subclause 8.7.1 is invoked with $\text{chromaEdgeFlag} = 1$, $iCbCr$, $\text{verticalEdgeFlag} = 1$, $\text{fieldModeFilteringFlag} = \text{fieldModeMbFlag}$, and $(xE_k, yE_k) = (0, k)$ with $k = 0..\text{MbHeightC} - 1$ as input and S'_C with C being replaced by Cb for $iCbCr = 0$ and C being replaced by Cr for $iCbCr = 1$ as output.
 - When $\text{filterInternalEdgesFlag}$ is equal to 1, the filtering of the internal vertical chroma edge is specified as follows.
 - The process specified in subclause 8.7.1 is invoked with $\text{chromaEdgeFlag} = 1$, $iCbCr$, $\text{verticalEdgeFlag} = 1$, $\text{fieldModeFilteringFlag} = \text{fieldModeMbFlag}$, and $(xE_k, yE_k) = (4, k)$ with $k = 0..\text{MbHeightC} - 1$ as input and S'_C with C being replaced by Cb for $iCbCr = 0$ and C being replaced by Cr for $iCbCr = 1$ as output.
 - When chroma_format_idc is equal to 3, the process specified in subclause 8.7.1 is invoked with $\text{chromaEdgeFlag} = 1$, $iCbCr$, $\text{verticalEdgeFlag} = 1$, $\text{fieldModeFilteringFlag} = \text{fieldModeMbFlag}$, and $(xE_k, yE_k) = (8, k)$ with $k = 0..\text{MbHeightC} - 1$ as input and S'_C with C being replaced by Cb for $iCbCr = 0$ and C being replaced by Cr for $iCbCr = 1$ as output.
 - When chroma_format_idc is equal to 3, the process specified in subclause 8.7.1 is invoked with $\text{chromaEdgeFlag} = 1$, $iCbCr$, $\text{verticalEdgeFlag} = 1$, $\text{fieldModeFilteringFlag} = \text{fieldModeMbFlag}$, and $(xE_k, yE_k) = (12, k)$ with $k = 0..\text{MbHeightC} - 1$ as input and S'_C with C being replaced by Cb for $iCbCr = 0$ and C being replaced by Cr for $iCbCr = 1$ as output.
- When $\text{filterTopMbEdgeFlag}$ is equal to 1, the filtering of the top horizontal chroma edge is specified as follows.
 - If MbaffFrameFlag is equal to 1, $(\text{CurrMbAddr} \% 2)$ is equal to 0, CurrMbAddr is greater than or equal to $2 * \text{PicWidthInMbs}$, the macroblock CurrMbAddr is a frame macroblock, and the macroblock $(\text{CurrMbAddr} - 2 * \text{PicWidthInMbs} + 1)$ is a field macroblock, the following applies.
 - The process specified in subclause 8.7.1 is invoked with $\text{chromaEdgeFlag} = 1$, $iCbCr$, $\text{verticalEdgeFlag} = 0$, $\text{fieldModeFilteringFlag} = 1$, and $(xE_k, yE_k) = (k, 0)$ with $k = 0..\text{MbWidthC} - 1$ as input and S'_C with C being replaced by Cb for $iCbCr = 0$ and C being replaced by Cr for $iCbCr = 1$ as output.
 - The process specified in subclause 8.7.1 is invoked with $\text{chromaEdgeFlag} = 1$, $iCbCr$, $\text{verticalEdgeFlag} = 0$, $\text{fieldModeFilteringFlag} = 1$, and $(xE_k, yE_k) = (k, 1)$ with $k = 0..\text{MbWidthC} - 1$ as input and S'_C with C being replaced by Cb for $iCbCr = 0$ and C being replaced by Cr for $iCbCr = 1$ as output.

- Otherwise, the process specified in subclause 8.7.1 is invoked with $\text{chromaEdgeFlag} = 1$, iCbCr , $\text{verticalEdgeFlag} = 0$, $\text{fieldModeFilteringFlag} = \text{fieldModeMbFlag}$, and $(x_{E_k}, y_{E_k}) = (k, 0)$ with $k = 0..MbWidthC - 1$ as input and S'_C with C being replaced by C_b for $\text{iCbCr} = 0$ and C being replaced by C_r for $\text{iCbCr} = 1$ as output.
- When $\text{filterInternalEdgesFlag}$ is equal to 1, the filtering of the internal horizontal chroma edge is specified as follows.
 - The process specified in subclause 8.7.1 is invoked with $\text{chromaEdgeFlag} = 1$, iCbCr , $\text{verticalEdgeFlag} = 0$, $\text{fieldModeFilteringFlag} = \text{fieldModeMbFlag}$, and $(x_{E_k}, y_{E_k}) = (k, 4)$ with $k = 0..MbWidthC - 1$ as input and S'_C with C being replaced by C_b for $\text{iCbCr} = 0$ and C being replaced by C_r for $\text{iCbCr} = 1$ as output.
 - When chroma_format_idc is not equal to 1, the process specified in subclause 8.7.1 is invoked with $\text{chromaEdgeFlag} = 1$, iCbCr , $\text{verticalEdgeFlag} = 0$, $\text{fieldModeFilteringFlag} = \text{fieldModeMbFlag}$, and $(x_{E_k}, y_{E_k}) = (k, 8)$ with $k = 0..MbWidthC - 1$ as input and S'_C with C being replaced by C_b for $\text{iCbCr} = 0$ and C being replaced by C_r for $\text{iCbCr} = 1$ as output.
 - When chroma_format_idc is not equal to 1, the process specified in subclause 8.7.1 is invoked with $\text{chromaEdgeFlag} = 1$, iCbCr , $\text{verticalEdgeFlag} = 0$, $\text{fieldModeFilteringFlag} = \text{fieldModeMbFlag}$, and $(x_{E_k}, y_{E_k}) = (k, 12)$ with $k = 0..MbWidthC - 1$ as input and S'_C with C being replaced by C_b for $\text{iCbCr} = 0$ and C being replaced by C_r for $\text{iCbCr} = 1$ as output.

NOTE 2 – When field mode filtering ($\text{fieldModeFilteringFlag}$ is equal to 1) is applied across the top horizontal edges of a frame macroblock, this vertical filtering across the top or bottom macroblock boundary may involve some samples that extend across an internal block edge that is also filtered internally in frame mode.

NOTE 3 – For example, in 4:2:0 chroma format when $\text{transform_size_8x8_flag}$ is equal to 0, the following applies. 3 horizontal luma edges, 1 horizontal chroma edge for C_b , and 1 horizontal chroma edge for C_r are filtered that are internal to a macroblock. When field mode filtering ($\text{fieldModeFilteringFlag}$ is equal to 1) is applied to the top edges of a frame macroblock, 2 horizontal luma, 2 horizontal chroma edges for C_b , and 2 horizontal chroma edges for C_r between the frame macroblock and the above macroblock pair are filtered using field mode filtering, for a total of up to 5 horizontal luma edges, 3 horizontal chroma edges for C_b , and 3 horizontal chroma edges for C_r filtered that are considered to be controlled by the frame macroblock. In all other cases, at most 4 horizontal luma, 2 horizontal chroma edges for C_b , and 2 horizontal chroma edges for C_r are filtered that are considered to be controlled by a particular macroblock.

Finally, the arrays S'_L , S'_{Cb} , S'_{Cr} are assigned to the arrays S_L , S_{Cb} , S_{Cr} (which represent the decoded picture), respectively.

8.7.1 Filtering process for block edges

Inputs to this process are chromaEdgeFlag , the chroma component index iCbCr (when chromaEdgeFlag is equal to 1), verticalEdgeFlag , $\text{fieldModeFilteringFlag}$, and a set of nE sample locations (x_{E_k}, y_{E_k}) , with $k = 0..nE - 1$, expressed relative to the upper left corner of the macroblock CurrMbAddr . The set of sample locations (x_{E_k}, y_{E_k}) represent the sample locations immediately to the right of a vertical edge (when verticalEdgeFlag is equal to 1) or immediately below a horizontal edge (when verticalEdgeFlag is equal to 0).

The variable nE is derived as follows.

- If chromaEdgeFlag is equal to 0, nE is set equal to 16.
- Otherwise (chromaEdgeFlag is equal to 1), nE is set equal to $(\text{verticalEdgeFlag} == 1) ? MbHeightC : MbWidthC$.

Let s' be a variable specifying a luma or chroma sample array, be derived as follows.

- If chromaEdgeFlag is equal to 0, s' represents the luma sample array S'_L of the current picture.
- Otherwise, if chromaEdgeFlag is equal to 1 and iCbCr is equal to 0, s' represents the chroma sample array S'_{Cb} of the chroma component C_b of the current picture.
- Otherwise (chromaEdgeFlag is equal to 1 and iCbCr is equal to 1), s' represents the chroma sample array S'_{Cr} of the chroma component C_r of the current picture.

The variable dy is derived as follows.

- If $\text{fieldModeFilteringFlag}$ is equal to 1 and MbaffFrameFlag is equal to 1, dy is set equal to 2.
- Otherwise ($\text{fieldModeFilteringFlag}$ is equal to 0 or MbaffFrameFlag is equal to 0), dy is set equal to 1.

The position of the upper-left luma sample of the macroblock CurrMbAddr is derived by invoking the inverse macroblock scanning process in subclause 6.4.1 with mbAddr = CurrMbAddr as input and the output being assigned to (xI, yI).

The variables xP and yP are derived as follows.

- If chromaEdgeFlag is equal to 0, xP is set equal to xI and yP is set equal to yI.
- Otherwise (chromaEdgeFlag is equal to 1), xP is set equal to xI / SubWidthC and yP is set equal to (yI + SubHeightC – 1) / SubHeightC.

Figure 8-11 – Convention for describing samples across a 4x4 block horizontal or vertical boundary

For each sample location (xE_k, yE_k), k = 0 .. nE – 1, the following applies.

- The filtering process is applied to a set of eight samples across a 4x4 block horizontal or vertical edge denoted as p_i and q_i with i = 0..3 as shown in Figure 8-11 with the edge lying between p₀ and q₀. p_i and q_i with i = 0..3 are specified as follows.

- If verticalEdgeFlag is equal to 1,

$$q_i = s'[xP + xE_k + i, yP + dy * yE_k] \quad (8-452)$$

$$p_i = s'[xP + xE_k - i - 1, yP + dy * yE_k] \quad (8-453)$$

- Otherwise (verticalEdgeFlag is equal to 0),

$$q_i = s'[xP + xE_k, yP + dy * (yE_k + i) - (yE_k \% 2)] \quad (8-454)$$

$$p_i = s'[xP + xE_k, yP + dy * (yE_k - i - 1) - (yE_k \% 2)] \quad (8-455)$$

- The process specified in subclause 8.7.2 is invoked with the sample values p_i and q_i (i = 0..3), chromaEdgeFlag, verticalEdgeFlag, and fieldModeFilteringFlag as input, and the output is assigned to the filtered result sample values p'_i and q'_i with i = 0..2.
- The input sample values p_i and q_i with i = 0..2 are replaced by the corresponding filtered result sample values p'_i and q'_i with i = 0..2 inside the sample array s' as follows.

- If verticalEdgeFlag is equal to 1,

$$s'[xP + xE_k + i, yP + dy * yE_k] = q'_i \quad (8-456)$$

$$s'[xP + xE_k - i - 1, yP + dy * yE_k] = p'_i \quad (8-457)$$

- Otherwise (verticalEdgeFlag is equal to 0),

$$s'[xP + xE_k, yP + dy * (yE_k + i) - (yE_k \% 2)] = q'_i \quad (8-458)$$

$$s'[xP + xE_k, yP + dy * (yE_k - i - 1) - (yE_k \% 2)] = p'_i \quad (8-459)$$

8.7.2 Filtering process for a set of samples across a horizontal or vertical block edge

Inputs to this process are the input sample values p_i and q_i with i in the range of 0..3 of a single set of samples across an edge that is to be filtered, `chromaEdgeFlag`, `verticalEdgeFlag`, and `fieldModeFilteringFlag`.

Outputs of this process are the filtered result sample values p'_i and q'_i with i in the range of 0..2.

The content dependent boundary filtering strength variable bS is derived as follows.

- If `chromaEdgeFlag` is equal to 0, the derivation process for the content dependent boundary filtering strength specified in subclause 8.7.2.1 is invoked with p_0 , q_0 , and `verticalEdgeFlag` as input, and the output is assigned to bS .
- Otherwise (`chromaEdgeFlag` is equal to 1), the bS used for filtering a set of samples of a horizontal or vertical chroma edge is set equal to the value of bS for filtering the set of samples of a horizontal or vertical luma edge, respectively, that contains the luma sample at location (`SubWidthC * x`, `SubHeightC * y`) inside the luma array of the same field, where (x , y) is the location of the chroma sample q_0 inside the chroma array for that field.

The process specified in subclause 8.7.2.2 is invoked with p_0 , q_0 , p_1 , q_1 , `chromaEdgeFlag`, and bS as input, and the output is assigned to `filterSamplesFlag`, `indexA`, α , and β .

Depending on the variable `filterSamplesFlag`, the following applies.

- If `filterSamplesFlag` is equal to 1, the following applies.
 - If bS is less than 4, the process specified in subclause 8.7.2.3 is invoked with p_i and q_i ($i = 0..2$), `chromaEdgeFlag`, bS , β , and `indexA` given as input, and the output is assigned to p'_i and q'_i ($i = 0..2$).
 - Otherwise (bS is equal to 4), the process specified in subclause 8.7.2.4 is invoked with p_i and q_i ($i = 0..3$), `chromaEdgeFlag`, α , and β given as input, and the output is assigned to p'_i and q'_i ($i = 0..2$).
- Otherwise (`filterSamplesFlag` is equal to 0), the filtered result samples p'_i and q'_i ($i = 0..2$) are replaced by the corresponding input samples p_i and q_i :

$$\text{for } i = 0..2, \quad p'_i = p_i \quad (8-460)$$

$$\text{for } i = 0..2, \quad q'_i = q_i \quad (8-461)$$

8.7.2.1 Derivation process for the luma content dependent boundary filtering strength

Inputs to this process are the input sample values p_0 and q_0 of a single set of samples across an edge that is to be filtered and `verticalEdgeFlag`.

Output of this process is the variable bS .

Let the variable `mixedModeEdgeFlag` be derived as follows.

- If `MbaffFrameFlag` is equal to 1 and the samples p_0 and q_0 are in different macroblock pairs, one of which is a field macroblock pair and the other is a frame macroblock pair, `mixedModeEdgeFlag` is set equal to 1
- Otherwise, `mixedModeEdgeFlag` is set equal to 0.

The variable bS is derived as follows.

- If the block edge is also a macroblock edge and any of the following conditions are true, a value of bS equal to 4 is the output:
 - the samples p_0 and q_0 are both in frame macroblocks and either or both of the samples p_0 or q_0 is in a macroblock coded using an Intra macroblock prediction mode
 - the samples p_0 and q_0 are both in frame macroblocks and either or both of the samples p_0 or q_0 is in a macroblock that is in a slice with `slice_type` equal to SP or SI
 - `MbaffFrameFlag` is equal to 1 or `field_pic_flag` is equal to 1, and `verticalEdgeFlag` is equal to 1, and either or both of the samples p_0 or q_0 is in a macroblock coded using an Intra macroblock prediction mode
 - `MbaffFrameFlag` is equal to 1 or `field_pic_flag` is equal to 1, and `verticalEdgeFlag` is equal to 1, and either or both of the samples p_0 or q_0 is in a macroblock that is in a slice with `slice_type` equal to SP or SI

- Otherwise, if any of the following conditions are true, a value of bS equal to 3 is the output:
 - mixedModeEdgeFlag is equal to 0 and either or both of the samples p_0 or q_0 is in a macroblock coded using an Intra macroblock prediction mode
 - mixedModeEdgeFlag is equal to 0 and either or both of the samples p_0 or q_0 is in a macroblock that is in a slice with slice_type equal to SP or SI
 - mixedModeEdgeFlag is equal to 1, verticalEdgeFlag is equal to 0, and either or both of the samples p_0 or q_0 is in a macroblock coded using an Intra macroblock prediction mode
 - mixedModeEdgeFlag is equal to 1, verticalEdgeFlag is equal to 0, and either or both of the samples p_0 or q_0 is in a macroblock that is in a slice with slice_type equal to SP or SI
- Otherwise, if the following condition is true, a value of bS equal to 2 is the output:
 - the luma block containing sample p_0 or the luma block containing sample q_0 contains non-zero transform coefficient levels
- Otherwise, if any of the following conditions are true, a value of bS equal to 1 is the output:
 - mixedModeEdgeFlag is equal to 1
 - mixedModeEdgeFlag is equal to 0 and for the prediction of the macroblock/sub-macroblock partition containing the sample p_0 different reference pictures or a different number of motion vectors are used than for the prediction of the macroblock/sub-macroblock partition containing the sample q_0 .
 NOTE 1 – The determination of whether the reference pictures used for the two macroblock/sub-macroblock partitions are the same or different is based only on which pictures are referenced, without regard to whether a prediction is formed using an index into reference picture list 0 or an index into reference picture list 1, and also without regard to whether or not the index position within a reference picture list is different or not.
 - mixedModeEdgeFlag is equal to 0 and one motion vector is used to predict the macroblock/sub-macroblock partition containing the sample p_0 and one motion vector is used to predict the macroblock/sub-macroblock partition containing the sample q_0 and the absolute difference between the horizontal or vertical component of the motion vectors used is greater than or equal to 4 in units of quarter luma frame samples.
 - mixedModeEdgeFlag is equal to 0 and two motion vectors and two different reference pictures are used to predict the macroblock/sub-macroblock partition containing the sample p_0 and two motion vectors for the same two reference pictures are used to predict the macroblock/sub-macroblock partition containing the sample q_0 and the absolute difference between the horizontal or vertical component of the two motion vectors used in the prediction of the two macroblock/sub-macroblock partitions for the same reference picture is greater than or equal to 4 in units of quarter luma frame samples.
 - mixedModeEdgeFlag is equal to 0 and two motion vectors for the same reference picture are used to predict the macroblock/sub-macroblock partition containing the sample p_0 and two motion vectors for the same reference picture are used to predict the macroblock/sub-macroblock partition containing the sample q_0 and both of the following conditions are true:
 - The absolute difference between the horizontal or vertical component of list 0 motion vectors used in the prediction of the two macroblock/sub-macroblock partitions is greater than or equal to 4 in quarter luma frame samples or the absolute difference between the horizontal or vertical component of the list 1 motion vectors used in the prediction of the two macroblock/sub-macroblock partitions is greater than or equal to 4 in units of quarter luma frame samples.
 - The absolute difference between the horizontal or vertical component of list 0 motion vector used in the prediction of the macroblock/sub-macroblock partition containing the sample p_0 and the list 1 motion vector used in the prediction of the macroblock/sub-macroblock partition containing the sample q_0 is greater than or equal to 4 in units of quarter luma frame samples or the absolute difference between the horizontal or vertical component of the list 1 motion vector used in the prediction of the macroblock/sub-macroblock partition containing the sample p_0 and list 0 motion vector used in the prediction of the macroblock/sub-macroblock partition containing the sample q_0 is greater than or equal to 4 in units of quarter luma frame samples.

NOTE 2 – A vertical difference of 4 in units of quarter luma frame samples is a difference of 2 in units of quarter luma field samples

- Otherwise, a value of bS equal to 0 is the output.

8.7.2.2 Derivation process for the thresholds for each block edge

Inputs to this process are the input sample values p_0 , q_0 , p_1 and q_1 of a single set of samples across an edge that is to be filtered, chromaEdgeFlag, and bS, for the set of input samples, as specified in 8.7.2.

Outputs of this process are the variable filterSamplesFlag, which indicates whether the input samples are filtered, the value of indexA, and the values of the threshold variables α and β .

Let qP_p and qP_q be variables specifying quantisation parameter values for the macroblocks containing the samples p_0 and q_0 , respectively. The variables qP_z (with z being replaced by p or q) are derived as follows.

- If chromaEdgeFlag is equal to 0, the following applies.
 - If the macroblock containing the sample z_0 is an I_PCM macroblock, qP_z is set to 0.
 - Otherwise (the macroblock containing the sample z_0 is not an I_PCM macroblock), qP_z is set to the value of QP_Y of the macroblock containing the sample z_0 .
- Otherwise (chromaEdgeFlag is equal to 1), the following applies.
 - If the macroblock containing the sample z_0 is an I_PCM macroblock, qP_z is set to the value of QP_C that corresponds to a value of 0 for QP_Y as specified in subclause 8.5.7.
 - Otherwise (the macroblock containing the sample z_0 is not an I_PCM macroblock), qP_z is set to the value of QP_C that corresponds to the value QP_Y of the macroblock containing the sample z_0 as specified in subclause 8.5.7.

Let qP_{av} be a variable specifying an average quantisation parameter. It is derived as follows.

$$qP_{av} = (qP_p + qP_q + 1) \gg 1 \quad (8-462)$$

NOTE – In SP and SI slices, qP_{av} is derived in the same way as in other slice types. QS_Y from Equation 7-28 is not used in the deblocking filter.

Let indexA be a variable that is used to access the α table (Table 8-16) as well as the t_{C0} table (Table 8-17), which is used in filtering of edges with bS less than 4 as specified in subclause 8.7.2.3, and let indexB be a variable that is used to access the β table (Table 8-16). The variables indexA and indexB are derived as follows, where the values of FilterOffsetA and FilterOffsetB are the values of those variables specified in subclause 7.4.3 for the slice that contains the macroblock containing sample q_0 .

$$\text{indexA} = \text{Clip3}(0, 51, qP_{av} + \text{FilterOffsetA}) \quad (8-463)$$

$$\text{indexB} = \text{Clip3}(0, 51, qP_{av} + \text{FilterOffsetB}) \quad (8-464)$$

The variables α' and β' depending on the values of indexA and indexB are specified in Table 8-16. Depending on chromaEdgeFlag, the corresponding threshold variables α and β are derived as follows.

- If chromaEdgeFlag is equal to 0,

$$\alpha = \alpha' * (1 \ll (\text{BitDepth}_Y - 8)) \quad (8-465)$$

$$\beta = \beta' * (1 \ll (\text{BitDepth}_Y - 8)) \quad (8-466)$$

- Otherwise (chromaEdgeFlag is equal to 1),

$$\alpha = \alpha' * (1 \ll (\text{BitDepth}_C - 8)) \quad (8-467)$$

$$\beta = \beta' * (1 \ll (\text{BitDepth}_C - 8)) \quad (8-468)$$

The variable filterSamplesFlag is derived by

$$\text{filterSamplesFlag} = (bS \neq 0 \ \&\& \ \text{Abs}(p_0 - q_0) < \alpha \ \&\& \ \text{Abs}(p_1 - p_0) < \beta \ \&\& \ \text{Abs}(q_1 - q_0) < \beta) \quad (8-469)$$

Table 8-16 – Derivation of offset dependent threshold variables α' and β' from indexA and indexB

	indexA (for α') or indexB (for β')

8.7.2.3 Filtering process for edges with bS less than 4

Inputs to this process are the input sample values p_i and q_i ($i = 0..2$) of a single set of samples across an edge that is to be filtered, chromaEdgeFlag, bS, β , and indexA, for the set of input samples, as specified in 8.7.2.

Outputs of this process are the filtered result sample values p'_i and q'_i ($i = 0..2$) for the set of input sample values.

The filtered result samples p'_0 and q'_0 are derived by

$$\Delta = \text{Clip3}(-t_c, t_c, (((q_0 - p_0) < 2) + (p_1 - q_1) + 4) >> 3)) \quad (8-470)$$

$$p'_0 = \text{Clip1}(p_0 + \Delta) \quad (8-471)$$

$$q'_0 = \text{Clip1}(q_0 - \Delta) \quad (8-472)$$

where the threshold t_c is determined as follows.

- If chromaEdgeFlag is equal to 0,

$$t_c = t_{c0} + ((a_p < \beta) ? 1 : 0) + ((a_q < \beta) ? 1 : 0) \quad (8-473)$$

- Otherwise (chromaEdgeFlag is equal to 1),

$$t_c = t_{c0} + 1 \quad (8-474)$$

Depending on the values of indexA and bS the variable t'_{c0} is specified in Table 8-17. Depending on chromaEdgeFlag, the corresponding threshold variable t_{c0} is derived as follows.

- If chromaEdgeFlag is equal to 0,

$$t_{c0} = t'_{c0} * (1 << (\text{BitDepth}_Y - 8)) \quad (8-475)$$

- Otherwise (chromaEdgeFlag is equal to 1),

$$t_{c0} = t'_{c0} * (1 << (\text{BitDepth}_C - 8)) \quad (8-476)$$

Let a_p and a_q be two threshold variables specified by

$$a_p = \text{Abs}(p_2 - p_0) \quad (8-477)$$

$$a_q = \text{Abs}(q_2 - q_0) \quad (8-478)$$

The filtered result sample p'_1 is derived as follows

- If chromaEdgeFlag is equal to 0 and a_p is less than β ,

$$p'_1 = p_1 + \text{Clip3}(-t_{C0}, t_{C0}, (p_2 + ((p_0 + q_0 + 1) \gg 1) - (p_1 \ll 1)) \gg 1) \quad (8-479)$$

- Otherwise (chromaEdgeFlag is equal to 1 or a_p is greater than or equal to β),

$$p'_1 = p_1 \quad (8-480)$$

The filtered result sample q'_1 is derived as follows

- If chromaEdgeFlag is equal to 0 and a_q is less than β ,

$$q'_1 = q_1 + \text{Clip3}(-t_{C0}, t_{C0}, (q_2 + ((p_0 + q_0 + 1) \gg 1) - (q_1 \ll 1)) \gg 1) \quad (8-481)$$

- Otherwise (chromaEdgeFlag is equal to 1 or a_q is greater than or equal to β),

$$q'_1 = q_1 \quad (8-482)$$

The filtered result samples p'_2 and q'_2 are always set equal to the input samples p_2 and q_2 :

$$p'_2 = p_2 \quad (8-483)$$

$$q'_2 = q_2 \quad (8-484)$$

8.7.2.4 Filtering process for edges for bS equal to 4

Inputs to this process are the input sample values p_i and q_i ($i = 0..3$) of a single set of samples across an edge that is to be filtered, the variable `chromaEdgeFlag`, and the values of the threshold variables α and β for the set of samples, as specified in subclause 8.7.2.

Outputs of this process are the filtered result sample values p'_i and q'_i ($i = 0..2$) for the set of input sample values.

Let a_p and a_q be two threshold variables as specified in Equations 8-477 and 8-478, respectively, in subclause 8.7.2.3.

The filtered result samples p'_i ($i = 0..2$) are derived as follows.

- If `chromaEdgeFlag` is equal to 0 and the following condition holds,

$$a_p < \beta \ \&\& \ \text{Abs}(p_0 - q_0) < ((\alpha >> 2) + 2) \quad (8-485)$$

then the variables p'_0 , p'_1 , and p'_2 are derived by

$$p'_0 = (p_2 + 2*p_1 + 2*p_0 + 2*q_0 + q_1 + 4) >> 3 \quad (8-486)$$

$$p'_1 = (p_2 + p_1 + p_0 + q_0 + 2) >> 2 \quad (8-487)$$

$$p'_2 = (2*p_3 + 3*p_2 + p_1 + p_0 + q_0 + 4) >> 3 \quad (8-488)$$

- Otherwise (`chromaEdgeFlag` is equal to 1 or the condition in Equation 8-485 does not hold), the variables p'_0 , p'_1 , and p'_2 are derived by

$$p'_0 = (2*p_1 + p_0 + q_1 + 2) >> 2 \quad (8-489)$$

$$p'_1 = p_1 \quad (8-490)$$

$$p'_2 = p_2 \quad (8-491)$$

The filtered result samples q'_i ($i = 0..2$) are derived as follows.

- If `chromaEdgeFlag` is equal to 0 and the following condition holds,

$$a_q < \beta \ \&\& \ \text{Abs}(p_0 - q_0) < ((\alpha >> 2) + 2) \quad (8-492)$$

then the variables q'_0 , q'_1 , and q'_2 are derived by

$$q'_0 = (p_1 + 2*p_0 + 2*q_0 + 2*q_1 + q_2 + 4) >> 3 \quad (8-493)$$

$$q'_1 = (p_0 + q_0 + q_1 + q_2 + 2) >> 2 \quad (8-494)$$

$$q'_2 = (2*q_3 + 3*q_2 + q_1 + q_0 + p_0 + 4) >> 3 \quad (8-495)$$

- Otherwise (`chromaEdgeFlag` is equal to 1 or the condition in Equation 8-492 does not hold), the variables q'_0 , q'_1 , and q'_2 are derived by

$$q'_0 = (2*q_1 + q_0 + p_1 + 2) >> 2 \quad (8-496)$$

$$q'_1 = q_1 \quad (8-497)$$

$$q'_2 = q_2 \quad (8-498)$$

9 Parsing process

Inputs to this process are bits from the RBSP.

Outputs of this process are syntax element values.

This process is invoked when the descriptor of a syntax element in the syntax tables in subclause 7.3 is equal to ue(v), me(v), se(v), te(v) (see subclause 9.1), ce(v) (see subclause 9.2), or ae(v) (see subclause 9.3).

9.1 Parsing process for Exp-Golomb codes

This process is invoked when the descriptor of a syntax element in the syntax tables in subclause 7.3 is equal to ue(v), me(v), se(v), or te(v). For syntax elements in subclauses 7.3.4 and 7.3.5, this process is invoked only when entropy_coding_mode_flag is equal to 0.

Inputs to this process are bits from the RBSP.

Outputs of this process are syntax element values.

Syntax elements coded as ue(v), me(v), or se(v) are Exp-Golomb-coded. Syntax elements coded as te(v) are truncated Exp-Golomb-coded. The parsing process for these syntax elements begins with reading the bits starting at the current location in the bitstream up to and including the first non-zero bit, and counting the number of leading bits that are equal to 0. This process is specified as follows:

```
leadingZeroBits = -1;
for( b = 0; !b; leadingZeroBits++ )
    b = read_bits( 1 )
```

The variable codeNum is then assigned as follows:

$$\text{codeNum} = 2^{\text{leadingZeroBits}} - 1 + \text{read_bits}(\text{leadingZeroBits})$$

where the value returned from read_bits(leadingZeroBits) is interpreted as a binary representation of an unsigned integer with most significant bit written first.

Table 9-1 illustrates the structure of the Exp-Golomb code by separating the bit string into “prefix” and “suffix” bits. The “prefix” bits are those bits that are parsed in the above pseudo-code for the computation of leadingZeroBits, and are shown as either 0 or 1 in the bit string column of Table 9-1. The “suffix” bits are those bits that are parsed in the computation of codeNum and are shown as x_i in Table 9-1, with i being in the range 0 to leadingZeroBits - 1, inclusive. Each x_i can take on values 0 or 1.

Table 9-1 – Bit strings with “prefix” and “suffix” bits and assignment to codeNum ranges (informative)

Bit string form	Range of codeNum
1	0
0 1 x_0	1-2
0 0 1 $x_1 x_0$	3-6
0 0 0 1 $x_2 x_1 x_0$	7-14
0 0 0 0 1 $x_3 x_2 x_1 x_0$	15-30
0 0 0 0 0 1 $x_4 x_3 x_2 x_1 x_0$	31-62
...	...

Table 9-2 illustrates explicitly the assignment of bit strings to codeNum values.

Table 9-2 – Exp-Golomb bit strings and codeNum in explicit form and used as ue(v) (informative)

Bit string	codeNum
1	0
0 1 0	1
0 1 1	2
0 0 1 0 0	3
0 0 1 0 1	4
0 0 1 1 0	5
0 0 1 1 1	6
0 0 0 1 0 0 0	7
0 0 0 1 0 0 1	8
0 0 0 1 0 1 0	9
...	...

Depending on the descriptor, the value of a syntax element is derived as follows.

- If the syntax element is coded as ue(v), the value of the syntax element is equal to codeNum.
- Otherwise, if the syntax element is coded as se(v), the value of the syntax element is derived by invoking the mapping process for signed Exp-Golomb codes as specified in subclause 9.1.1 with codeNum as the input.
- Otherwise, if the syntax element is coded as me(v), the value of the syntax element is derived by invoking the mapping process for coded block pattern as specified in subclause 9.1.2 with codeNum as the input.
- Otherwise (the syntax element is coded as te(v)), the range of possible values for the syntax element is determined first. The range of this syntax element may be between 0 and x, with x being greater than or equal to 1 and the range is used in the derivation of the value of the syntax element value as follows
 - If x is greater than 1, codeNum and the value of the syntax element is derived in the same way as for syntax elements coded as ue(v)
 - Otherwise (x is equal to 1), the parsing process for codeNum which is equal to the value of the syntax element is given by a process equivalent to:

$$b = \text{read_bits}(1)$$

$$\text{codeNum} = !b$$

9.1.1 Mapping process for signed Exp-Golomb codes

Input to this process is codeNum as specified in subclause 9.1.

Output of this process is a value of a syntax element coded as se(v).

The syntax element is assigned to the codeNum by ordering the syntax element by its absolute value in increasing order and representing the positive value for a given absolute value with the lower codeNum. Table 9-3 provides the assignment rule.

Table 9-3 – Assignment of syntax element to codeNum for signed Exp-Golomb coded syntax elements se(v)

codeNum	syntax element value
0	0
1	1
2	−1
3	2
4	−2
5	3
6	−3
k	$(-1)^{k+1} \text{Ceil}(k \div 2)$

9.1.2 Mapping process for coded block pattern

Input to this process is codeNum as specified in subclause 9.1.

Output of this process is a value of the syntax element coded_block_pattern coded as me(v).

Table 9-4 shows the assignment of coded_block_pattern to codeNum depending on whether the macroblock prediction mode is equal to Intra_4x4, Intra_8x8 or Inter.

Table 9-4 – Assignment of codeNum to values of coded_block_pattern for macroblock prediction modes

(a) chroma_format_idc is not equal to 0

9.2 CAVLC parsing process for transform coefficient levels

This process is invoked when parsing syntax elements with descriptor equal to ce(v) in subclause 7.3.5.3.1 and when entropy_coding_mode_flag is equal to 0.

Inputs to this process are bits from slice data, a maximum number of non-zero transform coefficient levels maxNumCoeff, the luma block index luma4x4BlkIdx or the chroma block index chroma4x4BlkIdx of the current block of transform coefficient levels.

Output of this process is the list coeffLevel containing transform coefficient levels of the luma block with block index luma4x4BlkIdx or the chroma block with block index chroma4x4BlkIdx.

The process is specified in the following ordered steps:

1. All transform coefficient levels, with indices from 0 to maxNumCoeff - 1, in the list coeffLevel are set equal to 0.
2. The total number of non-zero transform coefficient levels TotalCoeff(coeff_token) and the number of trailing one transform coefficient levels TrailingOnes(coeff_token) are derived by parsing coeff_token (see subclause 9.2.1) as follows.
 - If the number of non-zero transform coefficient levels TotalCoeff(coeff_token) is equal to 0, the list coeffLevel containing 0 values is returned and no further step is carried out.
 - Otherwise, the following steps are carried out.
 - a. The non-zero transform coefficient levels are derived by parsing trailing_ones_sign_flag, level_prefix, and level_suffix (see subclause 9.2.2).
 - b. The runs of zero transform coefficient levels before each non-zero transform coefficient level are derived by parsing total_zeros and run_before (see subclause 9.2.3).

- c. The level and run information are combined into the list `coeffLevel` (see subclause 9.2.4).

9.2.1 Parsing process for total number of transform coefficient levels and trailing ones

Inputs to this process are bits from slice data, a maximum number of non-zero transform coefficient levels `maxNumCoeff`, the luma block index `luma4x4BlkIdx` or the chroma block index `chroma4x4BlkIdx` of the current block of transform.

Outputs of this process are `TotalCoeff(coeff_token)` and `TrailingOnes(coeff_token)`.

The syntax element `coeff_token` is decoded using one of the six VLCs specified in the six right-most columns of Table 9-5. Each VLC specifies both `TotalCoeff(coeff_token)` and `TrailingOnes(coeff_token)` for a given codeword `coeff_token`. VLC selection is dependent upon a variable `nC` that is derived as follows.

- If the CAVLC parsing process is invoked for `ChromaDCLevel`, `nC` is derived as follows.
 - If `chroma_format_idc` is equal to 1, `nC` is set equal to -1,
 - Otherwise, if `chroma_format_idc` is equal to 2, `nC` is set equal to -2,
 - Otherwise (`chroma_format_idc` is equal to 3), `nC` is set equal to 0.
- Otherwise, the following applies.
 - When the CAVLC parsing process is invoked for `Intra16x16DCLevel`, `luma4x4BlkIdx` is set equal to 0.
 - The variables `blkA` and `blkB` are derived as follows.
 - If the CAVLC parsing process is invoked for `Intra16x16DCLevel`, `Intra16x16ACLevel`, or `LumaLevel`, the process specified in subclause 6.4.8.3 is invoked with `luma4x4BlkIdx` as the input, and the output is assigned to `mbAddrA`, `mbAddrB`, `luma4x4BlkIdxA`, and `luma4x4BlkIdxB`. The 4x4 luma block specified by `mbAddrA\luma4x4BlkIdxA` is assigned to `blkA`, and the 4x4 luma block specified by `mbAddrB\luma4x4BlkIdxB` is assigned to `blkB`.
 - Otherwise (the CAVLC parsing process is invoked for `ChromaACLevel`), the process specified in subclause 6.4.8.4 is invoked with `chroma4x4BlkIdx` as input, and the output is assigned to `mbAddrA`, `mbAddrB`, `chroma4x4BlkIdxA`, and `chroma4x4BlkIdxB`. The 4x4 chroma block specified by `mbAddrA\iCbCr\chroma4x4BlkIdxA` is assigned to `blkA`, and the 4x4 chroma block specified by `mbAddrB\iCbCr\chroma4x4BlkIdxB` is assigned to `blkB`.
 - Let `nA` and `nB` be the number of non-zero transform coefficient levels (given by `TotalCoeff(coeff_token)`) in the block of transform coefficient levels `blkA` located to the left of the current block and the block of transform coefficient levels `blkB` located above the current block, respectively.
 - With `N` replaced by `A` and `B`, in `mbAddrN`, `blkN`, and `nN` the following applies.
 - If any of the following conditions is true, `nN` is set equal to 0.
 - `mbAddrN` is not available
 - The current macroblock is coded using an Intra prediction mode, `constrained_intra_pred_flag` is equal to 1 and `mbAddrN` is coded using Inter prediction and slice data partitioning is in use (`nal_unit_type` is in the range of 2 to 4, inclusive).
 - The macroblock `mbAddrN` has `mb_type` equal to `P_Skip` or `B_Skip`
 - All AC residual transform coefficient levels of the neighbouring block `blkN` are equal to 0 due to the corresponding bit of `CodedBlockPatternLuma` or `CodedBlockPatternChroma` being equal to 0
 - Otherwise, if `mbAddrN` is an `I_PCM` macroblock, `nN` is set equal to 16.
 - Otherwise, `nN` is set equal to the value `TotalCoeff(coeff_token)` of the neighbouring block `blkN`.

NOTE 1 – The values `nA` and `nB` that are derived using `TotalCoeff(coeff_token)` do not include the DC transform coefficient levels in `Intra_16x16` macroblocks or DC transform coefficient levels in chroma blocks, because these transform coefficient levels are decoded separately. When the block above or to the left belongs to an `Intra_16x16` macroblock, or is a chroma block, `nA` and `nB` is the number of decoded non-zero AC transform coefficient levels.

NOTE 2 – When parsing for `Intra16x16DCLevel`, the values `nA` and `nB` are based on the number of non-zero transform coefficient levels in adjacent 4x4 blocks and not on the number of non-zero DC transform coefficient levels in adjacent 16x16 blocks.
- Given the values of `nA` and `nB`, the variable `nC` is derived as follows.

- If both mbAddrA and mbAddrB are available, the variable nC is set equal to $(nA + nB + 1) >> 1$.
- Otherwise (mbAddrA is not available or mbAddrB is not available), the variable nC is set equal to nA + nB.

The value of TotalCoeff(coeff_token) resulting from decoding coeff_token shall be in the range of 0 to maxNumCoeff, inclusive.

Table 9-5 – coeff_token mapping to TotalCoeff(coeff_token) and TrailingOnes(coeff_token)

TrailingOnes (coeff_token)	TotalCoeff (coeff_token)	$0 \leq nC < 2$	$2 \leq nC < 4$	$4 \leq nC < 8$	$8 \leq nC$	$nC = -1$	$nC = -2$

3	16	0000 0000 0000 1000	0000 0000 0001 00	0000 0000 10	1111 11	-	

9.2.2 Parsing process for level information

Inputs to this process are bits from slice data, the number of non-zero transform coefficient levels TotalCoeff(coeff_token), and the number of trailing one transform coefficient levels TrailingOnes(coeff_token).

Output of this process is a list with name level containing transform coefficient levels.

Initially an index i is set equal to 0. Then the following procedure is iteratively applied $\text{TrailingOnes}(\text{coeff_token})$ times to decode the trailing one transform coefficient levels (if any):

- A 1-bit syntax element $\text{trailing_ones_sign_flag}$ is decoded and evaluated as follows.
 - If $\text{trailing_ones_sign_flag}$ is equal to 0, the value +1 is assigned to $\text{level}[i]$.
 - Otherwise ($\text{trailing_ones_sign_flag}$ is equal to 1), the value -1 is assigned to $\text{level}[i]$.
- The index i is incremented by 1.

Following the decoding of the trailing one transform coefficient levels, a variable suffixLength is initialised as follows.

- If $\text{TotalCoeff}(\text{coeff_token})$ is greater than 10 and $\text{TrailingOnes}(\text{coeff_token})$ is less than 3, suffixLength is set equal to 1.
- Otherwise ($\text{TotalCoeff}(\text{coeff_token})$ is less than or equal to 10 or $\text{TrailingOnes}(\text{coeff_token})$ is equal to 3), suffixLength is set equal to 0.

The following procedure is then applied iteratively ($\text{TotalCoeff}(\text{coeff_token}) - \text{TrailingOnes}(\text{coeff_token})$) times to decode the remaining levels (if any):

- The syntax element level_prefix is decoded as specified in subclause 9.2.2.1.
- The variable levelSuffixSize is set equal to the variable suffixLength with the exception of the following two cases.
- When level_prefix is equal to 14 and suffixLength is equal to 0, levelSuffixSize is set equal to 4.
- When level_prefix is greater than or equal to 15, levelSuffixSize is set equal to $\text{level_prefix} - 3$.
- The syntax element level_suffix is decoded as follows.
 - If levelSuffixSize is greater than 0, the syntax element level_suffix is decoded as unsigned integer representation $u(v)$ with levelSuffixSize bits.
 - Otherwise (levelSuffixSize is equal to 0), the syntax element level_suffix is inferred to be equal to 0.
- A variable levelCode is set equal to $(\text{Min}(15, \text{level_prefix}) \ll \text{suffixLength}) + \text{level_suffix}$.
- When level_prefix is greater than or equal to 15 and suffixLength is equal to 0, levelCode is incremented by 15.
- When level_prefix is greater than or equal to 16, levelCode is incremented by $(1 \ll (\text{level_prefix} - 3)) - 4096$.
- When the index i is equal to $\text{TrailingOnes}(\text{coeff_token})$ and $\text{TrailingOnes}(\text{coeff_token})$ is less than 3, levelCode is incremented by 2.
- The variable $\text{level}[i]$ is derived as follows.
 - If levelCode is an even number, the value $(\text{levelCode} + 2) \gg 1$ is assigned to $\text{level}[i]$.
 - Otherwise (levelCode is an odd number), the value $(-\text{levelCode} - 1) \gg 1$ is assigned to $\text{level}[i]$.
- When suffixLength is equal to 0, suffixLength is set equal to 1.
- When the absolute value of $\text{level}[i]$ is greater than $(3 \ll (\text{suffixLength} - 1))$ and suffixLength is less than 6, suffixLength is incremented by 1.
- The index i is incremented by 1.

9.2.2.1 Parsing process for level_prefix

Inputs to this process are bits from slice data.

Output of this process is level_prefix .

The parsing process for this syntax element consists in reading the bits starting at the current location in the bitstream up to and including the first non-zero bit, and counting the number of leading bits that are equal to 0. This process is specified as follows:

```

leadingZeroBits = -1
for( b = 0; !b; leadingZeroBits++ )
    b = read_bits( 1 )
level_prefix = leadingZeroBits

```

Table 9-6 illustrates the codeword table for level_prefix.

Table 9-6 – Codeword table for level_prefix (informative)

level_prefix	bit string
0	1
1	01
2	001
3	0001

14	0000 0000 0000 001
15	0000 0000 0000 0001
...	...

9.2.3 Parsing process for run information

Inputs to this process are bits from slice data, the number of non-zero transform coefficient levels TotalCoeff(coeff_token), and the maximum number of non-zero transform coefficient levels maxNumCoeff.

Output of this process is a list of runs of zero transform coefficient levels preceding non-zero transform coefficient levels called run.

Initially, an index i is set equal to 0.

The variable zerosLeft is derived as follows.

- If the number of non-zero transform coefficient levels TotalCoeff(coeff_token) is equal to the maximum number of non-zero transform coefficient levels maxNumCoeff, a variable zerosLeft is set equal to 0.
- Otherwise (the number of non-zero transform coefficient levels TotalCoeff(coeff_token) is less than the maximum number of non-zero transform coefficient levels maxNumCoeff), total_zeros is decoded and zerosLeft is set equal to its value.

The VLC used to decode total_zeros is derived as follows:

If maxNumCoeff is equal to 4, one of the VLCs specified in Table 9-9 (a) is used.

- Otherwise, if maxNumCoeff is equal to 8, one of the VLCs specified in Table 9-9 (b) is used.
- Otherwise (maxNumCoeff is not equal to 4 and not equal to 8), VLCs from Tables 9-7 and 9-8 are used.

The following procedure is then applied iteratively (TotalCoeff(coeff_token) – 1) times:

- The variable run[i] is derived as follows.
 - If zerosLeft is greater than zero, a value run_before is decoded based on Table 9-10 and zerosLeft. run[i] is set equal to run_before.
 - Otherwise (zerosLeft is equal to 0), run[i] is set equal to 0.
- The value of run[i] is subtracted from zerosLeft and the result assigned to zerosLeft. The result of the subtraction shall be greater than or equal to 0.
- The index i is incremented by 1.

Finally the value of zerosLeft is assigned to run[i].

Table 9-7 – total_zeros tables for 4x4 blocks with TotalCoeff(coeff_token) 1 to 7

9.2.4 Combining level and run information

Input to this process are a list of transform coefficient levels called level, a list of runs called run, and the number of non-zero transform coefficient levels TotalCoeff(coeff_token).

Output of this process is an list coeffLevel of transform coefficient levels.

A variable coeffNum is set equal to -1 and an index i is set equal to (TotalCoeff(coeff_token) – 1). The following procedure is iteratively applied TotalCoeff(coeff_token) times:

- coeffNum is incremented by run[i] + 1.
- coeffLevel[coeffNum] is set equal to level[i].
- The index i is decremented by 1.

9.3 CABAC parsing process for slice data

This process is invoked when parsing syntax elements with descriptor ae(v) in subclauses 7.3.4 and 7.3.5 when entropy_coding_mode_flag is equal to 1.

Inputs to this process are a request for a value of a syntax element and values of prior parsed syntax elements.

Output of this process is the value of the syntax element.

When starting the parsing of the slice data of a slice in subclause 7.3.4, the initialisation process of the CABAC parsing process is invoked as specified in subclause 9.3.1.

The parsing of syntax elements proceeds as follows:

For each requested value of a syntax element a binarization is derived as described in subclause 9.3.2.

The binarization for the syntax element and the sequence of parsed bins determines the decoding process flow as described in subclause 9.3.3.

For each bin of the binarization of the syntax element, which is indexed by the variable `binIdx`, a context index `ctxIdx` is derived as specified in subclause 9.3.3.1.

For each `ctxIdx` the arithmetic decoding process is invoked as specified in subclause 9.3.3.2.

The resulting sequence ($b_0 \dots b_{\text{binIdx}}$) of parsed bins is compared to the set of bin strings given by the binarization process after decoding of each bin. When the sequence matches a bin string in the given set, the corresponding value is assigned to the syntax element.

In case the request for a value of a syntax element is processed for the syntax element `mb_type` and the decoded value of `mb_type` is equal to `I_PCM`, the decoding engine is initialised after the decoding of any `pcm_alignment_zero_bit` and all `pcm_sample_luma` and `pcm_sample_chroma` data as specified in subclause 9.3.1.2.

The whole CABAC parsing process is illustrated in the flowchart of Figure 9-1 with the abbreviation SE for syntax element.

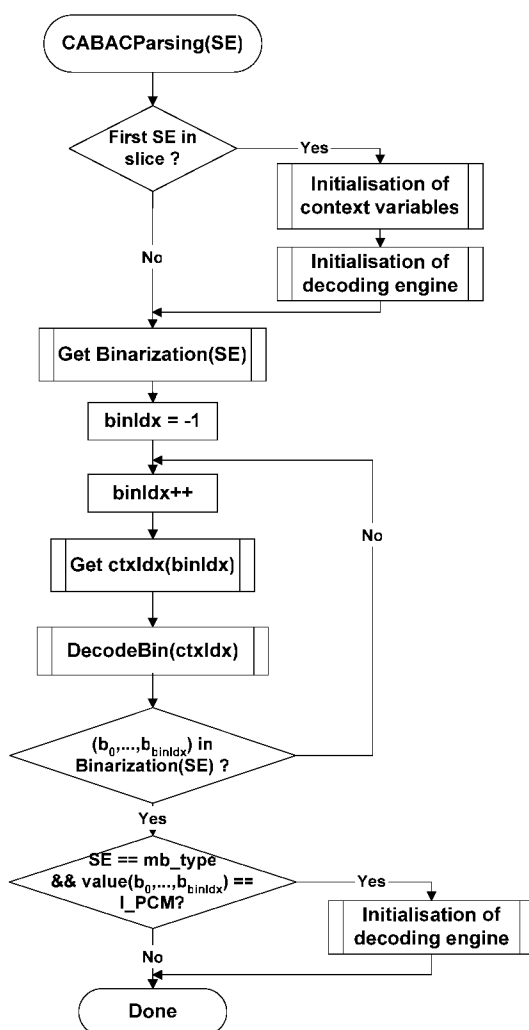

Figure 9-1 – Illustration of CABAC parsing process for a syntax element SE (informative)

9.3.1 Initialisation process

Outputs of this process are initialised CABAC internal variables.

The processes in subclauses 9.3.1.1 and 9.3.1.2 are invoked when starting the parsing of the slice data of a slice in subclause 7.3.4.

The process in subclause 9.3.1.2 is also invoked after decoding any pcm_alignment_zero_bit and all pcm_sample_luma and pcm_sample_chroma data for a macroblock of type I_PCM.

9.3.1.1 Initialisation process for context variables

Outputs of this process are the initialised CABAC context variables indexed by ctxIdx.

Table 9-12 to Table 9-23 contain the values of the variables n and m used in the initialisation of context variables that are assigned to all syntax elements in subclauses 7.3.4 and 7.3.5 except for the end-of-slice flag.

For each context variable, the two variables pStateIdx and valMPS are initialised.

NOTE 1 – The variable pStateIdx corresponds to a probability state index and the variable valMPS corresponds to the value of the most probable symbol as further described in subclause 9.3.3.2.

The two values assigned to pStateIdx and valMPS for the initialisation are derived from SliceQP_Y, which is derived in Equation 7-27. Given the two table entries (m, n),

1. $\text{preCtxState} = \text{Clip3}(1, 126, ((m * \text{Clip3}(0, 51, \text{SliceQP}_Y)) \gg 4) + n)$
2. $\text{if}(\text{preCtxState} \leq 63) \{$
 $\quad \text{pStateIdx} = 63 - \text{preCtxState}$
 $\quad \text{valMPS} = 0$
 $\quad \text{else} \{$
 $\quad \quad \text{pStateIdx} = \text{preCtxState} - 64$
 $\quad \quad \text{valMPS} = 1$
 $\quad \}$
 $\}$

In Table 9-11, the ctxIdx for which initialisation is needed for each of the slice types are listed. Also listed is the table number that includes the values of m and n needed for the initialisation. For P, SP and B slice type, the initialisation depends also on the value of the cabac_init_idc syntax element. Note that the syntax element names do not affect the initialisation process.

Table 9-11 – Association of ctxIdx and syntax elements for each slice type in the initialisation process

	coeff_abs_level_minus1[]	Table 9-21 Table 9-24	227-275	227-275 426-435	227-275 426-435	227-275 426-435

NOTE 2 – ctxIdx equal to 276 is associated with the end_of_slice_flag and the bin of mb_type, which specifies the I_PCM macroblock type. The decoding process specified in subclause 9.3.3.2.4 applies to ctxIdx equal to 276. This decoding process, however, may also be implemented by using the decoding process specified in subclause 9.3.3.2.1. In this case, the initial values associated with ctxIdx equal to 276 are specified to be pStateIdx = 63 and valMPS = 0, where pStateIdx = 63 represents a non-adapting probability state.

Table 9-12 – Values of variables m and n for ctxIdx from 0 to 10

9.3.1.2 Initialisation process for the arithmetic decoding engine

This process is invoked before decoding the first macroblock of a slice or after the decoding of any pcm_alignment_zero_bit and all pcm_sample_luma and pcm_sample_chroma data for a macroblock of type I_PCM.

Outputs of this process are the initialised decoding engine registers codIRange and codIOffset both in 16 bit register precision.

The status of the arithmetic decoding engine is represented by the variables codIRange and codIOffset. In the initialisation procedure of the arithmetic decoding process, codIRange is set equal to 0x01FE and codIOffset is set equal

to the value returned from `read_bits(9)` interpreted as a 9 bit binary representation of an unsigned integer with most significant bit written first.

The bitstream shall not contain data that results in a value of `codIOffset` being equal to 0x01FE or 0x01FF.

NOTE – The description of the arithmetic decoding engine in this Recommendation | International Standard utilizes 16 bit register precision. However, the minimum register precision for the variables `codIRange` and `codIOffset` is 9 bits.

9.3.2 Binarization process

Input to this process is a request for a syntax element.

Output of this process is the binarization of the syntax element, `maxBinIdxCtx`, `ctxIdxOffset`, and `bypassFlag`.

Table 9-25 specifies the type of binarization process, `maxBinIdxCtx`, and `ctxIdxOffset` associated with each syntax element.

The specification of the unary (U) binarization process, the truncated unary (TU) binarization process, the concatenated unary / k-th order Exp-Golomb (UEGk) binarization process, and the fixed-length (FL) binarization process are given in subclauses 9.3.2.1 to 9.3.2.4, respectively. Other binarizations are specified in subclauses 9.3.2.5 to 9.3.2.7.

Except for I slices, the binarizations for the syntax element `mb_type` as specified in subclause 9.3.2.5 consist of bin strings given by a concatenation of prefix and suffix bit strings. The UEGk binarization as specified in 9.3.2.3, which is used for the binarization of the syntax elements `mvd_IX` ($X = 0, 1$) and `coeff_abs_level_minus1`, and the binarization of the `coded_block_pattern` also consist of a concatenation of prefix and suffix bit strings. For these binarization processes, the prefix and the suffix bit string are separately indexed using the `binIdx` variable as specified further in subclause 9.3.3. The two sets of prefix bit strings and suffix bit strings are referred to as the binarization prefix part and the binarization suffix part, respectively.

Associated with each binarization or binarization part of a syntax element is a specific value of the context index offset (`ctxIdxOffset`) variable and a specific value of the `maxBinIdxCtx` variable as given in Table 9-25. When two values for each of these variables are specified for one syntax element in Table 9-25, the value in the upper row is related to the prefix part while the value in the lower row is related to the suffix part of the binarization of the corresponding syntax element.

The use of the `DecodeBypass` process and the variable `bypassFlag` is derived as follows.

- If no value is assigned to `ctxIdxOffset` for the corresponding binarization or binarization part in Table 9-25 labelled as “na”, all bins of the bit strings of the corresponding binarization or of the binarization prefix/suffix part are decoded by invoking the `DecodeBypass` process as specified in subclause 9.3.3.2.3. In such a case, `bypassFlag` is set equal to 1, where `bypassFlag` is used to indicate that for parsing the value of the bin from the bitstream the `DecodeBypass` process is applied.
- Otherwise, for each possible value of `binIdx` up to the specified value of `maxBinIdxCtx` given in Table 9-25, a specific value of the variable `ctxIdx` is further specified in subclause 9.3.3. `bypassFlag` is set equal to 0.

The possible values of the context index `ctxIdx` are in the range 0 to 459, inclusive. The value assigned to `ctxIdxOffset` specifies the lower value of the range of `ctxIdx` assigned to the corresponding binarization or binarization part of a syntax element.

`ctxIdx = ctxIdxOffset = 276` is assigned to the syntax element `end_of_slice_flag` and the bin of `mb_type`, which specifies the I_PCM macroblock type as further specified in subclause 9.3.3.1. For parsing the value of the corresponding bin from the bitstream, the arithmetic decoding process for decisions before termination (`DecodeTerminate`) as specified in subclause 9.3.3.2.4 is applied.

NOTE – The bins of `mb_type` in I slices and the bins of the suffix for `mb_type` in SI slices that correspond to the same value of `binIdx` share the same `ctxIdx`. The last bin of the prefix of `mb_type` and the first bin of the suffix of `mb_type` in P, SP, and B slices may share the same `ctxIdx`.

Table 9-25 – Syntax elements and associated types of binarization, maxBinIdxCtx, and ctxIdxOffset

Syntax element	Type of binarization	maxBinIdxCtx	ctxIdxOffset
mb_type (SI slices only)	prefix and suffix as specified in subclause 9.3.2.5	prefix: 0 suffix: 6	prefix: 0 suffix: 3
mb_type (I slices only)	as specified in subclause 9.3.2.5	6	3

coded_block_flag	FL, cMax=1	0	85
significant_coeff_flag (frame coded blocks with ctxBlockCat < 5)	FL, cMax=1	0	105
last_significant_coeff_flag (frame coded blocks with ctxBlockCat < 5)	FL, cMax=1	0	166
coeff_abs_level_minus1 (blocks with ctxBlockCat < 5)	prefix and suffix as given by UEG0 with signedValFlag=0, uCoff=14	prefix: 1 suffix: na	prefix: 227 suffix: na, (uses DecodeBypass)
coeff_sign_flag	FL, cMax=1	0	na, (uses DecodeBypass)
end_of_slice_flag	FL, cMax=1	0	276
significant_coeff_flag (field coded blocks with ctxBlockCat < 5)	FL, cMax=1	0	277

Syntax element	Type of binarization	maxBinIdxCtx	ctxIdxOffset
last_significant_coeff_flag (field coded blocks with ctxBlockCat < 5)	FL, cMax=1	0	338
transform_size_8x8_flag	FL, cMax=1	0	399
significant_coeff_flag (frame coded blocks with ctxBlockCat == 5)	FL, cMax=1	0	402
last_significant_coeff_flag (frame coded blocks with ctxBlockCat == 5)	FL, cMax=1	0	417
coeff_abs_level_minus1 (blocks with ctxBlockCat == 5)	prefix and suffix as given by UEG0 with signedValFlag=0, uCoff=14	prefix: 1 suffix: na	prefix: 426 suffix: na, (uses DecodeBypass)
significant_coeff_flag (field coded blocks with ctxBlockCat == 5)	FL, cMax=1	0	436
last_significant_coeff_flag (field coded blocks with ctxBlockCat == 5)	FL, cMax=1	0	451

9.3.2.1 Unary (U) binarization process

Input to this process is a request for a U binarization for a syntax element.

Output of this process is the U binarization of the syntax element.

The bin string of a syntax element having (unsigned integer) value synElVal is a bit string of length synElVal + 1 indexed by BinIdx. The bins for binIdx less than synElVal are equal to 1. The bin with binIdx equal to synElVal is equal to 0.

Table 9-26 illustrates the bin strings of the unary binarization for a syntax element.

Table 9-26 – Bin string of the unary binarization (informative)

Value of syntax element	Bin string					
0 (I_NxN)	0					
1	1	0				
2	1	1	0			
3	1	1	1	0		
4	1	1	1	1	0	
5	1	1	1	1	1	0
...						
binIdx	0	1	2	3	4	5

9.3.2.2 Truncated unary (TU) binarization process

Input to this process is a request for a TU binarization for a syntax element and cMax.

Output of this process is the TU binarization of the syntax element.

For syntax element (unsigned integer) values less than cMax, the U binarization process as specified in subclause 9.3.2.1 is invoked. For the syntax element value equal to cMax the bin string is a bit string of length cMax with all bins being equal to 1.

NOTE – TU binarization is always invoked with a cMax value equal to the largest possible value of the syntax element being decoded.

9.3.2.3 Concatenated unary/ k-th order Exp-Golomb (UEGk) binarization process

Input to this process is a request for a UEGk binarization for a syntax element, signedValFlag and uCoff.

Output of this process is the UEGk binarization of the syntax element.

A UEGk bin string is a concatenation of a prefix bit string and a suffix bit string. The prefix of the binarization is specified by invoking the TU binarization process for the prefix part $\text{Min}(\text{uCoff}, \text{Abs}(\text{synElVal}))$ of a syntax element value synElVal as specified in subclause 9.3.2.2 with cMax = uCoff, where uCoff > 0.

The UEGk bin string is derived as follows.

- If one of the following is true, the bin string of a syntax element having value synElVal consists only of a prefix bit string,
 - signedValFlag is equal to 0 and the prefix bit string is not equal to the bit string of length uCoff with all bits equal to 1.
 - signedValFlag is equal to 1 and the prefix bit string is equal to the bit string that consists of a single bit with value equal to 0.
- Otherwise, the bin string of the UEGk suffix part of a syntax element value synElVal is specified by a process equivalent to the following pseudo-code:

```
if( Abs( synElVal ) >= uCoff ) {
    sufS = Abs( synElVal ) - uCoff
    stopLoop = 0
    do {
        if( sufS >= ( 1 << k ) ) {
            put( 1 )
            sufS = sufS - ( 1 << k )
            k++
        } else {
            put( 0 )
            while( k-- )
                put( ( sufS >> k ) & 0x01 )
            stopLoop = 1
        }
    } while( !stopLoop )
}
if( signedValFlag && synElVal != 0 )
    if( synElVal > 0 )
        put( 0 )
    else
        put( 1 )
```

NOTE – The specification for the k-th order Exp-Golomb (EGk) code uses 1's and 0's in reverse meaning for the unary part of the Exp-Golomb code of 0-th order as specified in subclause 9.1.

9.3.2.4 Fixed-length (FL) binarization process

Input to this process is a request for a FL binarization for a syntax element and cMax.

Output of this process is the FL binarization of the syntax element.

FL binarization is constructed by using an fixedLength-bit unsigned integer bin string of the syntax element value, where $\text{fixedLength} = \text{Ceil}(\text{Log}_2(\text{cMax} + 1))$. The indexing of bins for the FL binarization is such that the binIdx = 0 relates to the least significant bit with increasing values of binIdx towards the most significant bit.

9.3.2.5 Binarization process for macroblock type and sub-macroblock type

Input to this process is a request for a binarization for syntax elements mb_type or sub_mb_type.

Output of this process is the binarization of the syntax element.

The binarization scheme for decoding of macroblock type in I slices is specified in Table 9-27.

For macroblock types in SI slices, the binarization consists of bin strings specified as a concatenation of a prefix and a suffix bit string as follows.

The prefix bit string consists of a single bit, which is specified by $b_0 = ((mb_type == SI) ? 0 : 1)$. For the syntax element value for which b_0 is equal to 0, the bin string only consists of the prefix bit string. For the syntax element value for which b_0 is equal to 1, the binarization is given by concatenating the prefix b_0 and the suffix bit string as specified in Table 9-27 for macroblock type in I slices indexed by subtracting 1 from the value of mb_type in SI slices.

Table 9-27 – Binarization for macroblock types in I slices

Value (name) of mb_type	Bin string						
0 (I_4x4)	0						
1 (I_16x16_0_0_0)	1	0	0	0	0	0	
2 (I_16x16_1_0_0)	1	0	0	0	0	1	
3 (I_16x16_2_0_0)	1	0	0	0	1	0	
4 (I_16x16_3_0_0)	1	0	0	0	1	1	
5 (I_16x16_0_1_0)	1	0	0	1	0	0	0
6 (I_16x16_1_1_0)	1	0	0	1	0	0	1
7 (I_16x16_2_1_0)	1	0	0	1	0	1	0
8 (I_16x16_3_1_0)	1	0	0	1	0	1	1
9 (I_16x16_0_2_0)	1	0	0	1	1	0	0
10 (I_16x16_1_2_0)	1	0	0	1	1	0	1
11 (I_16x16_2_2_0)	1	0	0	1	1	1	0
12 (I_16x16_3_2_0)	1	0	0	1	1	1	1
13 (I_16x16_0_0_1)	1	0	1	0	0	0	
14 (I_16x16_1_0_1)	1	0	1	0	0	1	
15 (I_16x16_2_0_1)	1	0	1	0	1	0	
16 (I_16x16_3_0_1)	1	0	1	0	1	1	
17 (I_16x16_0_1_1)	1	0	1	1	0	0	0
18 (I_16x16_1_1_1)	1	0	1	1	0	0	1
19 (I_16x16_2_1_1)	1	0	1	1	0	1	0
20 (I_16x16_3_1_1)	1	0	1	1	0	1	1
21 (I_16x16_0_2_1)	1	0	1	1	1	0	0
22 (I_16x16_1_2_1)	1	0	1	1	1	0	1
23 (I_16x16_2_2_1)	1	0	1	1	1	1	0
24 (I_16x16_3_2_1)	1	0	1	1	1	1	1
25 (I_PCM)	1	1					
binIdx	0	1	2	3	4	5	6

The binarization schemes for P macroblock types in P and SP slices and for B macroblocks in B slices are specified in Table 9-28.

The bin string for I macroblock types in P and SP slices corresponding to mb_type values 5 to 30 consists of a concatenation of a prefix, which consists of a single bit with value equal to 1 as specified in Table 9-28 and a suffix as specified in Table 9-27, indexed by subtracting 5 from the value of mb_type .

mb_type equal to 4 (P_8x8ref0) is not allowed.

For I macroblock types in B slices (mb_type values 23 to 48) the binarization consists of bin strings specified as a concatenation of a prefix bit string as specified in Table 9-28 and suffix bit strings as specified in Table 9-27, indexed by subtracting 23 from the value of mb_type.

Table 9-28 – Binarization for macroblock types in P, SP, and B slices

Slice type	Value (name) of mb_type	Bin string							
P, SP slice	0 (P_L0_16x16)	0	0	0					
	1 (P_L0_L0_16x8)	0	1	1					
	2 (P_L0_L0_8x16)	0	1	0					
	3 (P_8x8)	0	0	1					
	4 (P_8x8ref0)	na							
	5 to 30 (Intra, prefix only)	1							
B slice	0 (B_Direct_16x16)	0							
	1 (B_L0_16x16)	1	0	0					
	2 (B_L1_16x16)	1	0	1					
	3 (B_Bi_16x16)	1	1	0	0	0	0		
	4 (B_L0_L0_16x8)	1	1	0	0	0	1		
	5 (B_L0_L0_8x16)	1	1	0	0	1	0		
	6 (B_L1_L1_16x8)	1	1	0	0	1	1		
	7 (B_L1_L1_8x16)	1	1	0	1	0	0		
	8 (B_L0_L1_16x8)	1	1	0	1	0	1		
	9 (B_L0_L1_8x16)	1	1	0	1	1	0		
	10 (B_L1_L0_16x8)	1	1	0	1	1	1		
	11 (B_L1_L0_8x16)	1	1	1	1	1	0		
	12 (B_L0_Bi_16x8)	1	1	1	0	0	0	0	
	13 (B_L0_Bi_8x16)	1	1	1	0	0	0	1	
	14 (B_L1_Bi_16x8)	1	1	1	0	0	1	0	
	15 (B_L1_Bi_8x16)	1	1	1	0	0	1	1	
	16 (B_Bi_L0_16x8)	1	1	1	0	1	0	0	
	17 (B_Bi_L0_8x16)	1	1	1	0	1	0	1	
	18 (B_Bi_L1_16x8)	1	1	1	0	1	1	0	
	19 (B_Bi_L1_8x16)	1	1	1	0	1	1	1	
	20 (B_Bi_Bi_16x8)	1	1	1	1	0	0	0	
	21 (B_Bi_Bi_8x16)	1	1	1	1	0	0	1	
	22 (B_8x8)	1	1	1	1	1	1		
	23 to 48 (Intra, prefix only)	1	1	1	1	0	1		
binIdx		0	1	2	3	4	5	6	

For P, SP, and B slices the specification of the binarization for sub_mb_type is given in Table 9-29.

Table 9-29 – Binarization for sub-macroblock types in P, SP, and B slices

Slice type	Value (name) of sub_mb_type	Bin string					
P, SP slice	0 (P_L0_8x8)	1					
	1 (P_L0_8x4)	0	0				
	2 (P_L0_4x8)	0	1	1			
	3 (P_L0_4x4)	0	1	0			
B slice	0 (B_Direct_8x8)	0					
	1 (B_L0_8x8)	1	0	0			
	2 (B_L1_8x8)	1	0	1			
	3 (B_Bi_8x8)	1	1	0	0	0	
	4 (B_L0_8x4)	1	1	0	0	1	
	5 (B_L0_4x8)	1	1	0	1	0	
	6 (B_L1_8x4)	1	1	0	1	1	
	7 (B_L1_4x8)	1	1	1	0	0	0
	8 (B_Bi_8x4)	1	1	1	0	0	1
	9 (B_Bi_4x8)	1	1	1	0	1	0
	10 (B_L0_4x4)	1	1	1	0	1	1
	11 (B_L1_4x4)	1	1	1	1	0	
	12 (B_Bi_4x4)	1	1	1	1	1	
binIdx		0	1	2	3	4	5

9.3.2.6 Binarization process for coded block pattern

Input to this process is a request for a binarization for the syntax element coded_block_pattern.

Output of this process is the binarization of the syntax element.

The binarization of coded_block_pattern consists of a prefix part and (when present) a suffix part. The prefix part of the binarization is given by the FL binarization of CodedBlockPatternLuma with cMax = 15. When chroma_format_idc is not equal to 0 (monochrome), the suffix part is present and consists of the TU binarization of CodedBlockPatternChroma with cMax = 2. The relationship between the value of the syntax element coded_block_pattern and the values of CodedBlockPatternLuma and CodedBlockPatternChroma is given as specified in subclause 7.4.5.

9.3.2.7 Binarization process for mb_qp_delta

Input to this process is a request for a binarization for the syntax element mb_qp_delta.

Output of this process is the binarization of the syntax element.

The bin string of mb_qp_delta is derived by the U binarization of the mapped value of the syntax element mb_qp_delta, where the assignment rule between the signed value of mb_qp_delta and its mapped value is given as specified in Table 9-3.

9.3.3 Decoding process flow

Input to this process is a binarization of the requested syntax element, maxBinIdxCtx, bypassFlag and ctxIdxOffset as specified in subclause 9.3.2.

Output of this process is the value of the syntax element.

This process specifies how each bit of a bit string is parsed for each syntax element.

After parsing each bit, the resulting bit string is compared to all bin strings of the binarization of the syntax element and the following applies.

- If the bit string is equal to one of the bin strings, the corresponding value of the syntax element is the output.
- Otherwise (the bit string is not equal to one of the bin strings), the next bit is parsed.

While parsing each bin, the variable `binIdx` is incremented by 1 starting with `binIdx` being set equal to 0 for the first bin.

When the binarization of the corresponding syntax element consists of a prefix and a suffix binarization part,, the variable `binIdx` is set equal to 0 for the first bin of each part of the bin string (prefix part or suffix part). In this case, after parsing the prefix bit string, the parsing process of the suffix bit string related to the binarizations specified in subclauses 9.3.2.3 and 9.3.2.5 is invoked depending on the resulting prefix bit string as specified in subclauses 9.3.2.3 and 9.3.2.5. Note that for the binarization of the syntax element `coded_block_pattern`, the suffix bit string is present regardless of the prefix bit string of length 4 as specified in subclause 9.3.2.6.

Depending on the variable `bypassFlag`, the following applies.

- If `bypassFlag` is equal to 1, the bypass decoding process as specified in subclause 9.3.3.2.3 is applied for parsing the value of the bins from the bitstream.
- Otherwise (`bypassFlag` is equal to 0), the parsing of each bin is specified by the following two ordered steps:
 1. Given `binIdx`, `maxBinIdxCtx` and `ctxIdxOffset`, `ctxIdx` is derived as specified in subclause 9.3.3.1.
 2. Given `ctxIdx`, the value of the bin from the bitstream as specified in subclause 9.3.3.2 is decoded.

9.3.3.1 Derivation process for `ctxIdx`

Inputs to this process are `binIdx`, `maxBinIdxCtx` and `ctxIdxOffset`.

Output of this process is `ctxIdx`.

Table 9-30 shows the assignment of `ctxIdx` increments (`ctxIdxInc`) to `binIdx` for all `ctxIdxOffset` values except those related to the syntax elements `coded_block_flag`, `significant_coeff_flag`, `last_significant_coeff_flag`, and `coeff_abs_level_minus1`.

The `ctxIdx` to be used with a specific `binIdx` is specified by first determining the `ctxIdxOffset` associated with the given bin string or part thereof. The `ctxIdx` is determined as follows.

- If the `ctxIdxOffset` is listed in Table 9-30, the `ctxIdx` for a `binIdx` is the sum of `ctxIdxOffset` and `ctxIdxInc`, which is found in Table 9-30. When more than one value is listed in Table 9-30 for a `binIdx`, the assignment process for `ctxIdxInc` for that `binIdx` is further specified in the subclauses given in parenthesis of the corresponding table entry.
- Otherwise (`ctxIdxOffset` is not listed in Table 9-30), the `ctxIdx` is specified to be the sum of the following terms: `ctxIdxOffset` and `ctxIdxBlockCatOffset(ctxBlockCat)` as specified in Table 9-31 and `ctxIdxInc(ctxBlockCat)`. Subclause 9.3.3.1.3 specifies which `ctxBlockCat` is used. Subclause 9.3.3.1.9 specifies the assignment of `ctxIdxInc(ctxBlockCat)` for `coded_block_flag`, and subclause 9.3.3.1.3 specifies the assignment of `ctxIdxInc(ctxBlockCat)` for `significant_coeff_flag`, `last_significant_coeff_flag`, and `coeff_abs_level_minus1`.

All bins with `binIdx` greater than `maxBinIdxCtx` are parsed using the value of `ctxIdx` being assigned to `binIdx` equal to `maxBinIdxCtx`.

All entries in Table 9-30 labelled with “na” correspond to values of `binIdx` that do not occur for the corresponding `ctxIdxOffset`.

`ctxIdx = 276` is assigned to the `binIdx` of `mb_type` indicating the `I_PCM` mode. For parsing the value of the corresponding bins from the bitstream, the arithmetic decoding process for decisions before termination as specified in subclause 9.3.3.2.4 is applied.

Table 9-30 – Assignment of ctxIdxInc to binIdx for all ctxIdxOffset values except those related to the syntax elements coded_block_flag, significant_coeff_flag, last_significant_coeff_flag, and coeff_abs_level_minus1

ctxIdxOffset	binIdx						
	0	1	2	3	4	5	>= 6
0	0,1,2 (subclause 9.3.3.1.1.3)	na	na	na	na	na	na
3	0,1,2 (subclause 9.3.3.1.1.3)	ctxIdx=276	3	4	5,6 (subclause 9.3.3.1.2)	6,7 (subclause 9.3.3.1.2)	7
11	0,1,2 (subclause 9.3.3.1.1.1)	na	na	na	na	na	na
14	0	1	2,3 (subclause 9.3.3.1.2)	na	na	na	na
17	0	ctxIdx=276	1	2	2,3 (subclause 9.3.3.1.2)	3	3
21	0	1	2	na	na	na	na
24	0,1,2 (subclause 9.3.3.1.1.1)	na	na	na	na	na	na
27	0,1,2 (subclause 9.3.3.1.1.3)	3	4,5 (subclause 9.3.3.1.2)	5	5	5	5
32	0	ctxIdx=276	1	2	2,3 (subclause 9.3.3.1.2)	3	3
36	0	1	2,3 (subclause 9.3.3.1.2)	3	3	3	na
40	0,1,2 (subclause 9.3.3.1.1.7)	3	4	5	6	6	6
47	0,1,2 (subclause 9.3.3.1.1.7)	3	4	5	6	6	6
54	0,1,2,3 (subclause 9.3.3.1.1.6)	4	5	5	5	5	5
60	0,1 (subclause 9.3.3.1.1.5)	2	3	3	3	3	3
64	0,1,2 (subclause 9.3.3.1.1.8)	3	3	na	na	na	na
68	0	na	na	na	na	na	na
69	0	0	0	na	na	na	na
70	0,1,2 (subclause 9.3.3.1.1.2)	na	na	na	na	na	na
73	0,1,2,3 (subclause 9.3.3.1.1.4)	0,1,2,3 (subclause 9.3.3.1.1.4)	0,1,2,3 (subclause 9.3.3.1.1.4)	0,1,2,3 (subclause 9.3.3.1.1.4)	na	na	na
77	0,1,2,3 (subclause 9.3.3.1.1.4)	4,5,6,7 (subclause 9.3.3.1.1.4)	na	na	na	na	na
276	0	na	na	na	na	na	na
399	0,1,2 (subclause 9.3.3.1.1.10)	na	na	na	na	na	na

Table 9-31 shows the values of `ctxIdxBlockCatOffset` depending on `ctxBlockCat` for the syntax elements `coded_block_flag`, `significant_coeff_flag`, `last_significant_coeff_flag`, and `coeff_abs_level_minus1`. The specification of `ctxBlockCat` is given in Table 9-33.

Table 9-31 – Assignment of `ctxIdxBlockCatOffset` to `ctxBlockCat` for syntax elements `coded_block_flag`, `significant_coeff_flag`, `last_significant_coeff_flag`, and `coeff_abs_level_minus1`

Syntax element	ctxBlockCat (as specified in Table 9-33)					
	0	1	2	3	4	5
<code>coded_block_flag</code>	0	4	8	12	16	na
<code>significant_coeff_flag</code>	0	15	29	44	47	0
<code>last_significant_coeff_flag</code>	0	15	29	44	47	0
<code>coeff_abs_level_minus1</code>	0	10	20	30	39	0

9.3.3.1.1 Assignment process of `ctxIdxInc` using neighbouring syntax elements

Subclause 9.3.3.1.1.1 specifies the derivation process of `ctxIdxInc` for the syntax element `mb_skip_flag`.

Subclause 9.3.3.1.1.2 specifies the derivation process of `ctxIdxInc` for the syntax element `mb_field_decoding_flag`.

Subclause 9.3.3.1.1.3 specifies the derivation process of `ctxIdxInc` for the syntax element `mb_type`.

Subclause 9.3.3.1.1.4 specifies the derivation process of `ctxIdxInc` for the syntax element `coded_block_pattern`.

Subclause 9.3.3.1.1.5 specifies the derivation process of `ctxIdxInc` for the syntax element `mb_qp_delta`.

Subclause 9.3.3.1.1.6 specifies the derivation process of `ctxIdxInc` for the syntax elements `ref_idx_l0` and `ref_idx_l1`.

Subclause 9.3.3.1.1.7 specifies the derivation process of `ctxIdxInc` for the syntax elements `mvd_l0` and `mvd_l1`.

Subclause 9.3.3.1.1.8 specifies the derivation process of `ctxIdxInc` for the syntax element `intra_chroma_pred_mode`.

Subclause 9.3.3.1.1.9 specifies the derivation process of `ctxIdxInc` for the syntax element `coded_block_flag`.

Subclause 9.3.3.1.1.10 specifies the derivation process of `ctxIdxInc` for the syntax element `transform_size_8x8_flag`.

9.3.3.1.1.1 Derivation process of `ctxIdxInc` for the syntax element `mb_skip_flag`

Output of this process is `ctxIdxInc`.

When `MbaffFrameFlag` is equal to 1 and `mb_field_decoding_flag` has not been decoded (yet) for the current macroblock pair with top macroblock address $2 * (\text{CurrMbAddr} / 2)$, the inference rule for the syntax element `mb_field_decoding_flag` as specified in subclause 7.4.4 is applied.

The derivation process for neighbouring macroblocks specified in subclause 6.4.8.1 is invoked and the output is assigned to `mbAddrA` and `mbAddrB`.

Let the variable `condTermFlagN` (with `N` being either `A` or `B`) be derived as follows.

- If `mbAddrN` is not available or `mb_skip_flag` for the macroblock `mbAddrN` is equal to 1, `condTermFlagN` is set equal to 0.
- Otherwise (`mbAddrN` is available and `mb_skip_flag` for the macroblock `mbAddrN` is equal to 0), `condTermFlagN` is set equal to 1.

The variable `ctxIdxInc` is derived by

$$\text{ctxIdxInc} = \text{condTermFlagA} + \text{condTermFlagB} \quad (9-1)$$

9.3.3.1.1.2 Derivation process of `ctxIdxInc` for the syntax element `mb_field_decoding_flag`

Output of this process is `ctxIdxInc`.

The derivation process for neighbouring macroblock addresses and their availability in MBAFF frames as specified in subclause 6.4.7 is invoked and the output is assigned to `mbAddrA` and `mbAddrB`.

When both macroblocks mbAddrN and mbAddrN + 1 have mb_type equal to P_Skip or B_Skip, the inference rule for the syntax element mb_field_decoding_flag as specified in subclause 7.4.4 is applied for the macroblock mbAddrN.

Let the variable condTermFlagN (with N being either A or B) be derived as follows.

- If any of the following conditions is true, condTermFlagN is set equal to 0,
 - mbAddrN is not available
 - the macroblock mbAddrN is a frame macroblock.
- Otherwise, condTermFlagN is set equal to 1.

The variable ctxIdxInc is derived by

$$\text{ctxIdxInc} = \text{condTermFlagA} + \text{condTermFlagB} \quad (9-2)$$

9.3.3.1.1.3 Derivation process of ctxIdxInc for the syntax element mb_type

Input to this process is ctxIdxOffset.

Output of this process is ctxIdxInc.

The derivation process for neighbouring macroblocks specified in subclause 6.4.8.1 is invoked and the output is assigned to mbAddrA and mbAddrB.

Let the variable condTermFlagN (with N being either A or B) be derived as follows.

- If any of the following conditions is true, condTermFlagN is set equal to 0
 - mbAddrN is not available
 - ctxIdxOffset is equal to 0 and mb_type for the macroblock mbAddrN is equal to SI
 - ctxIdxOffset is equal to 3 and mb_type for the macroblock mbAddrN is equal to I_NxN
 - ctxIdxOffset is equal to 27 and mb_type for the macroblock mbAddrN is equal to P_Skip, B_Skip, or B_Direct_16x16
- Otherwise, condTermFlagN is set equal to 1.

The variable ctxIdxInc is derived as

$$\text{ctxIdxInc} = \text{condTermFlagA} + \text{condTermFlagB} \quad (9-3)$$

9.3.3.1.1.4 Derivation process of ctxIdxInc for the syntax element coded_block_pattern

Inputs to this process are ctxIdxOffset and binIdx.

Output of this process is ctxIdxInc.

Depending on the value of the variable ctxIdxOffset, the following applies.

- If ctxIdxOffset is equal to 73, the following applies
 - The derivation process for neighbouring 8x8 luma blocks specified in subclause 6.4.8.2 is invoked with luma8x8BlkIdx = binIdx as input and the output is assigned to mbAddrA, mbAddrB, luma8x8BlkIdxA, and luma8x8BlkIdxB.
 - Let the variable condTermFlagN (with N being either A or B) be derived as follows.
 - If any of the following conditions are true, condTermFlagN is set equal to 0
 - mbAddrN is not available
 - mb_type for the macroblock mbAddrN is equal to I_PCM
 - the macroblock mbAddrN is not the current macroblock CurrMbAddr and the macroblock mbAddrN does not have mb_type equal to P_Skip or B_Skip, and ((CodedBlockPatternLuma >> luma8x8BlkIdxN) & 1) is not equal to 0 for the value of CodedBlockPatternLuma for the macroblock mbAddrN

- the macroblock mbAddrN is the current macroblock CurrMbAddr and the prior decoded bin value b_k of coded_block_pattern with $k = \text{luma8x8BlkIdxN}$ is not equal to 0.
- Otherwise, condTermFlagN is set equal to 1.
- The variable ctxIdxInc is derived as

$$\text{ctxIdxInc} = \text{condTermFlagA} + 2 * \text{condTermFlagB} \quad (9-4)$$

- Otherwise (ctxIdxOffset is equal to 77), the following applies.
 - The derivation process for neighbouring macroblocks specified in subclause 6.4.8.1 is invoked and the output is assigned to mbAddrA and mbAddrB.
 - Let the variable condTermFlagN (with N being either A or B) be derived as follows.
 - If mbAddrN is available and mb_type for the macroblock mbAddrN is equal to I_PCM, condTermFlagN is set equal to 1
 - Otherwise, if any of the following conditions is true, condTermFlagN is set equal to 0
 - mbAddrN is not available or the macroblock mbAddrN has mb_type equal to P_Skip or B_Skip
 - binIdx is equal to 0 and CodedBlockPatternChroma for the macroblock mbAddrN is equal to 0
 - binIdx is equal to 1 and CodedBlockPatternChroma for the macroblock mbAddrN is not equal to 2
 - Otherwise, condTermFlagN is set equal to 1.
 - The variable ctxIdxInc is derived as

$$\text{ctxIdxInc} = \text{condTermFlagA} + 2 * \text{condTermFlagB} + ((\text{binIdx} == 1) ? 4 : 0) \quad (9-5)$$

NOTE – When a macroblock uses an Intra_16x16 prediction mode, the values of CodedBlockPatternLuma and CodedBlockPatternChroma for the macroblock are derived from mb_type as specified in Table 7-11.

9.3.3.1.1.5 Derivation process of ctxIdxInc for the syntax element mb_qp_delta

Output of this process is ctxIdxInc.

Let prevMbAddr be the macroblock address of the macroblock that precedes the current macroblock in decoding order. When the current macroblock is the first macroblock of a slice, prevMbAddr is marked as not available.

Let the variable ctxIdxInc be derived as follows.

- If any of the following conditions is true, ctxIdxInc is set equal to 0
 - prevMbAddr is not available or the macroblock prevMbAddr has mb_type equal to P_Skip or B_Skip
 - mb_type of the macroblock prevMbAddr is equal to I_PCM
 - The macroblock prevMbAddr is not coded in Intra_16x16 prediction mode and both CodedBlockPatternLuma and CodedBlockPatternChroma for the macroblock prevMbAddr are equal to 0
 - mb_qp_delta for the macroblock prevMbAddr is equal to 0
- Otherwise, ctxIdxInc is set equal to 1.

9.3.3.1.1.6 Derivation process of ctxIdxInc for the syntax elements ref_idx_l0 and ref_idx_l1

Input to this process is mbPartIdx.

Output of this process is ctxIdxInc.

The interpretation of ref_idx_lX and Pred_LX within this subclause is specified as follows.

- If this process is invoked for the derivation of ref_idx_l0, ref_idx_lX is interpreted as ref_idx_l0 and Pred_LX is interpreted as Pred_L0.
- Otherwise (this process is invoked for the derivation of ref_idx_l1), ref_idx_lX is interpreted as ref_idx_l1 and Pred_LX is interpreted as Pred_L1.

Let currSubMbType be set equal to sub_mb_type[mbPartIdx].

The derivation process for neighbouring partitions specified in subclause 6.4.8.5 is invoked with mbPartIdx, currSubMbType, and subMbPartIdx = 0 as input and the output is assigned to mbAddrA\mbPartIdxA and mbAddrB\mbPartIdxB.

With ref_idx_IX[mbPartIdxN] (with N being either A or B) specifying the syntax element for the macroblock mbAddrN, let the variable refIdxZeroFlagN be derived as follows.

- If MbaffFrameFlag is equal to 1, the current macroblock is a frame macroblock, and the macroblock mbAddrN is a field macroblock

$$\text{refIdxZeroFlagN} = ((\text{ref_idx_IX}[\text{mbPartIdxN}] > 1) ? 0 : 1) \quad (9-6)$$

- Otherwise,

$$\text{refIdxZeroFlagN} = ((\text{ref_idx_IX}[\text{mbPartIdxN}] > 0) ? 0 : 1) \quad (9-7)$$

Let the variable predModeEqualFlagN be specified as follows.

- If the macroblock mbAddrN has mb_type equal to P_8x8 or B_8x8, the following applies.
 - If SubMbPredMode(sub_mb_type[mbPartIdxN]) is not equal to Pred_LX and not equal to BiPred, predModeEqualFlagN is set equal to 0, where sub_mb_type specifies the syntax element for the macroblock mbAddrN.
 - Otherwise, predModeEqualFlagN is set equal to 1.
- Otherwise, the following applies.
 - If MbPartPredMode(mb_type, mbPartIdxN) is not equal to Pred_LX and not equal to BiPred, predModeEqualFlagN is set equal to 0, where mb_type specifies the syntax element for the macroblock mbAddrN.
 - Otherwise, predModeEqualFlagN is set equal to 1.

Let the variable condTermFlagN (with N being either A or B) be derived as follows.

- If any of the following conditions is true, condTermFlagN is set equal to 0
 - mbAddrN is not available
 - the macroblock mbAddrN has mb_type equal to P_Skip or B_Skip
 - The macroblock mbAddrN is coded in Intra prediction mode
 - predModeEqualFlagN is equal to 0
 - refIdxZeroFlagN is equal to 1
- Otherwise, condTermFlagN is set equal to 1.

The variable ctxIdxInc is derived as

$$\text{ctxIdxInc} = \text{condTermFlagA} + 2 * \text{condTermFlagB} \quad (9-8)$$

9.3.3.1.1.7 Derivation process of ctxIdxInc for the syntax elements mvd_l0 and mvd_l1

Inputs to this process are mbPartIdx, subMbPartIdx, and ctxIdxOffset.

Output of this process is ctxIdxInc.

The interpretation of mvd_IX and Pred_LX within this subclause is specified as follows.

- If this process is invoked for the derivation of mvd_l0, mvd_IX is interpreted as mvd_l0 and Pred_LX is interpreted as Pred_L0.
- Otherwise (this process is invoked for the derivation of mvd_l1), mvd_IX is interpreted as mvd_l1 and Pred_LX is interpreted as Pred_L1.

Let currSubMbType be set equal to sub_mb_type[mbPartIdx].

The derivation process for neighbouring partitions specified in subclause 6.4.8.5 is invoked with mbPartIdx, currSubMbType, and subMbPartIdx as input and the output is assigned to mbAddrA\mbPartIdxA\subMbPartIdxA and mbAddrB\mbPartIdxB\subMbPartIdxB.

Let the variable compIdx be derived as follows.

- If ctxIdxOffset is equal to 40, compIdx is set equal to 0.
- Otherwise (ctxIdxOffset is equal to 47), compIdx is set equal to 1.

Let the variable predModeEqualFlagN be specified as follows.

- If the macroblock mbAddrN has mb_type equal to P_8x8 or B_8x8, the following applies.
 - If SubMbPredMode(sub_mb_type[mbPartIdxN]) is not equal to Pred_LX and not equal to BiPred, predModeEqualFlagN is set equal to 0, where sub_mb_type specifies the syntax element for the macroblock mbAddrN.
 - Otherwise, predModeEqualFlagN is set equal to 1.
- Otherwise, the following applies.
 - If MbPartPredMode(mb_type, mbPartIdxN) is not equal to Pred_LX and not equal to BiPred, predModeEqualFlagN is set equal to 0, where mb_type specifies the syntax element for the macroblock mbAddrN.
 - Otherwise, predModeEqualFlagN is set equal to 1.

Let the variable absMvdCompN (with N being either A or B) be derived as follows.

- If any of the following conditions is true, absMvdCompN is set equal to 0
 - mbAddrN is not available
 - the macroblock mbAddrN has mb_type equal to P_Skip or B_Skip
 - The macroblock mbAddrN is coded in an Intra prediction mode
 - predModeEqualFlagN is equal to 0
- Otherwise, the following applies
 - If compIdx is equal to 1, MbaffFrameFlag is equal to 1, the current macroblock is a frame macroblock, and the macroblock mbAddrN is a field macroblock

$$\text{absMvdCompN} = \text{Abs}(\text{mvd_IX}[\text{mbPartIdxN}][\text{subMbPartIdxN}][\text{compIdx}]) * 2 \quad (9-9)$$

- Otherwise, if compIdx is equal to 1, MbaffFrameFlag is equal to 1, the current macroblock is a field macroblock, and the macroblock mbAddrN is a frame macroblock

$$\text{absMvdCompN} = \text{Abs}(\text{mvd_IX}[\text{mbPartIdxN}][\text{subMbPartIdxN}][\text{compIdx}]) / 2 \quad (9-10)$$

- Otherwise,

$$\text{absMvdCompN} = \text{Abs}(\text{mvd_IX}[\text{mbPartIdxN}][\text{subMbPartIdxN}][\text{compIdx}]) \quad (9-11)$$

The variable ctxIdxInc is derived as follows

- If (absMvdCompA + absMvdCompB) is less than 3, ctxIdxInc is set equal to 0.
- Otherwise, if (absMvdCompA + absMvdCompB) is greater than 32, ctxIdxInc is set equal to 2.
- Otherwise ((absMvdCompA + absMvdCompB) is in the range of 3 to 32, inclusive), ctxIdxInc is set equal to 1.

9.3.3.1.1.8 Derivation process of ctxIdxInc for the syntax element intra_chroma_pred_mode

Output of this process is ctxIdxInc.

The derivation process for neighbouring macroblocks specified in subclause 6.4.8.1 is invoked and the output is assigned to mbAddrA and mbAddrB.

Let the variable `condTermFlagN` (with `N` being replaced by either `A` or `B`) be derived as follows.

- If any of the following conditions is true, `condTermFlagN` is set equal to 0
 - `mbAddrN` is not available
 - The macroblock `mbAddrN` is coded in Inter prediction mode
 - `mb_type` for the macroblock `mbAddrN` is equal to `I_PCM`
 - `intra_chroma_pred_mode` for the macroblock `mbAddrN` is equal to 0
- Otherwise, `condTermFlagN` is set equal to 1.

The variable `ctxIdxInc` is derived by

$$\text{ctxIdxInc} = \text{condTermFlagA} + \text{condTermFlagB} \quad (9-12)$$

9.3.3.1.1.9 Derivation process of `ctxIdxInc` for the syntax element `coded_block_flag`

Input to this process is `ctxBlockCat` and additional input is specified as follows.

- If `ctxBlockCat` is equal to 0, no additional input
- Otherwise, if `ctxBlockCat` is equal to 1 or 2, `luma4x4BlkIdx`
- Otherwise, if `ctxBlockCat` is equal to 3, the chroma component index `iCbCr`
- Otherwise (`ctxBlockCat` is equal to 4), `chroma4x4BlkIdx` and the chroma component index `iCbCr`

Output of this process is `ctxIdxInc(ctxBlockCat)`.

Let the variable `transBlockN` (with `N` being either `A` or `B`) be derived as follows.

- If `ctxBlockCat` is equal to 0, the following applies.
 - The derivation process for neighbouring macroblocks specified in subclause 6.4.8.1 is invoked and the output is assigned to `mbAddrN` (with `N` being either `A` or `B`).
 - The variable `transBlockN` is derived as follows.
 - If `mbAddrN` is available and the macroblock `mbAddrN` is coded in `Intra_16x16` prediction mode, the luma DC block of macroblock `mbAddrN` is assigned to `transBlockN`
 - Otherwise, `transBlockN` is marked as not available.
- Otherwise, if `ctxBlockCat` is equal to 1 or 2, the following applies.
 - The derivation process for neighbouring 4x4 luma blocks specified in subclause 6.4.8.3 is invoked with `luma4x4BlkIdx` as input and the output is assigned to `mbAddrN`, `luma4x4BlkIdxN` (with `N` being either `A` or `B`).
 - The variable `transBlockN` is derived as follows.
 - If `mbAddrN` is available, the macroblock `mbAddrN` does not have `mb_type` equal to `P_Skip`, `B_Skip`, or `I_PCM`, $((\text{CodedBlockPatternLuma} \gg (\text{luma4x4BlkIdxN} \gg 2)) \& 1)$ is not equal to 0 for the macroblock `mbAddrN`, and `transform_size_8x8_flag` is equal to 0 for the macroblock `mbAddrN`, the 4x4 luma block with index `luma4x4BlkIdxN` of macroblock `mbAddrN` is assigned to `transBlockN`.
 - Otherwise, if `mbAddrN` is available, the macroblock `mbAddrN` does not have `mb_type` equal to `P_Skip` or `B_Skip`, $((\text{CodedBlockPatternLuma} \gg (\text{luma4x4BlkIdxN} \gg 2)) \& 1)$ is not equal to 0 for the macroblock `mbAddrN`, and `transform_size_8x8_flag` is equal to 1 for the macroblock `mbAddrN`, the 8x8 luma block with index $(\text{luma4x4BlkIdxN} \gg 2)$ of macroblock `mbAddrN` is assigned to `transBlockN`.
 - Otherwise, `transBlockN` is marked as not available.
- Otherwise, if `ctxBlockCat` is equal to 3, the following applies.
 - The derivation process for neighbouring macroblocks specified in subclause 6.4.8.1 is invoked and the output is assigned to `mbAddrN` (with `N` being either `A` or `B`).
 - The variable `transBlockN` is derived as follows.

- If mbAddrN is available, the macroblock mbAddrN does not have mb_type equal to P_Skip, B_Skip, or I_PCM, and CodedBlockPatternChroma is not equal to 0 for the macroblock mbAddrN, the chroma DC block of chroma component iCbCr of macroblock mbAddrN is assigned to transBlockN.
- Otherwise, transBlockN is marked as not available.
- Otherwise (ctxBlockCat is equal to 4), the following applies.
 - The derivation process for neighbouring 4x4 chroma blocks specified in subclause 6.4.8.4 is invoked with chroma4x4BlkIdx as input and the output is assigned to mbAddrN, chroma4x4BlkIdxN (with N being either A or B).
 - The variable transBlockN is derived as follows.
 - If mbAddrN is available, the macroblock mbAddrN does not have mb_type equal to P_Skip, B_Skip, or I_PCM, and CodedBlockPatternChroma is equal to 2 for the macroblock mbAddrN, the 4x4 chroma block with chroma4x4BlkIdxN of the chroma component iCbCr of macroblock mbAddrN is assigned to transBlockN.
 - Otherwise, transBlockN is marked as not available.

Let the variable condTermFlagN (with N being either A or B) be derived as follows.

- If any of the following conditions is true, condTermFlagN is set equal to 0
 - mbAddrN is not available and the current macroblock is coded in Inter prediction mode
 - mbAddrN is available and transBlockN is not available and mb_type for the macroblock mbAddrN is not equal to I_PCM
 - The current macroblock is coded in Intra prediction mode, constrained_intra_pred_flag is equal to 1, the macroblock mbAddrN is available and coded in Inter prediction mode, and slice data partitioning is in use (nal_unit_type is in the range of 2 through 4, inclusive).
- Otherwise, if any of the following conditions is true, condTermFlagN is set equal to 1
 - mbAddrN is not available and the current macroblock is coded in Intra prediction mode
 - mb_type for the macroblock mbAddrN is equal to I_PCM
- Otherwise, condTermFlagN is set equal to the value of the coded_block_flag of the transform block transBlockN that was decoded for the macroblock mbAddrN.

The variable ctxIdxInc(ctxBlockCat) is derived by

$$\text{ctxIdxInc}(\text{ctxBlockCat}) = \text{condTermFlagA} + 2 * \text{condTermFlagB} \quad (9-13)$$

9.3.3.1.1.10 Derivation process of ctxIdxInc for the syntax element transform_size_8x8_flag

Output of this process is ctxIdxInc.

The derivation process for neighbouring macroblocks specified in subclause 6.4.8.1 is invoked and the output is assigned to mbAddrA and mbAddrB.

Let the variable condTermFlagN (with N being either A or B) be derived as follows.

- If any of the following conditions is true, condTermFlagN is set equal to 0.
 - mbAddrN is not available
 - transform_size_8x8_flag for the macroblock mbAddrN is equal to 0
- Otherwise, condTermFlagN is set equal to 1.

The variable ctxIdxInc is derived by

$$\text{ctxIdxInc} = \text{condTermFlagA} + \text{condTermFlagB} \quad (9-14)$$

9.3.3.1.2 Assignment process of ctxIdxInc using prior decoded bin values

Inputs to this process are ctxIdxOffset and binIdx.

Output of this process is ctxIdxInc.

Table 9-32 contains the specification of ctxIdxInc for the given values of ctxIdxOffset and binIdx.

For each value of ctxIdxOffset and binIdx, ctxIdxInc is derived by using some of the values of prior decoded bin values ($b_0, b_1, b_2, \dots, b_k$), where the value of the index k is less than the value of binIdx.

Table 9-32 – Specification of ctxIdxInc for specific values of ctxIdxOffset and binIdx

Value (name) of ctxIdxOffset	binIdx	ctxIdxInc
3	4	$(b_3 \neq 0) ? 5 : 6$
	5	$(b_3 \neq 0) ? 6 : 7$
14	2	$(b_1 \neq 1) ? 2 : 3$
17	4	$(b_3 \neq 0) ? 2 : 3$
27	2	$(b_1 \neq 0) ? 4 : 5$
32	4	$(b_3 \neq 0) ? 2 : 3$
36	2	$(b_1 \neq 0) ? 2 : 3$

9.3.3.1.3 Assignment process of ctxIdxInc for syntax elements significant_coeff_flag, last_significant_coeff_flag, and coeff_abs_level_minus1

Inputs to this process are ctxIdxOffset and binIdx.

Output of this process is ctxIdxInc.

The assignment process of ctxIdxInc for syntax elements significant_coeff_flag, last_significant_coeff_flag, and coeff_abs_level_minus1 as well as for coded_block_flag depends on categories of different blocks denoted by the variable ctxBlockCat. The specification of these block categories is given in Table 9-33.

Table 9-33 – Specification of ctxBlockCat for the different blocks

Block description	maxNumCoeff	ctxBlockCat
block of luma DC transform coefficient levels (i.e., list Intra16x16DCLevel as described in subclause 7.4.5.3)	16	0
block of luma AC transform coefficient levels (i.e., list Intra16x16ACLevel[i] as described in subclause 7.4.5.3)	15	1
block of 16 luma transform coefficient levels (i.e., list LumaLevel[i] as described in subclause 7.4.5.3)	16	2
block of chroma DC transform coefficient levels	$4 * \text{NumC8x8}$	3
block of chroma AC transform coefficient levels	15	4
block of 64 luma transform coefficient levels (i.e., list LumaLevel8x8[i] as described in subclause 7.4.5.3)	64	5

Let the variable levelListIdx be set equal to the index of the list of transform coefficient levels as specified in subclause 7.4.5.3.

For the syntax elements significant_coeff_flag and last_significant_coeff_flag in blocks with ctxBlockCat < 5 and ctxBlockCat != 3, the variable ctxIdxInc is derived by

$$\text{ctxIdxInc} = \text{levelListIdx} \quad (9-15)$$

where levelListIdx ranges from 0 to maxNumCoeff – 2, inclusive.

For the syntax elements significant_coeff_flag and last_significant_coeff_flag in blocks with ctxBlockCat == 3, the variable ctxIdxInc is derived by

$$\text{ctxIdxInc} = \text{Min}(\text{levelListIdx} / \text{NumC8x8}, 2) \quad (9-16)$$

where levelListIdx ranges from 0 to $4 * \text{NumC8x8} - 2$, inclusive.

For the syntax elements `significant_coeff_flag` and `last_significant_coeff_flag` in 8x8 luma blocks with `ctxBlockCat == 5`, Table 9-34 contains the specification of `ctxIdxInc` for the given values of `levelListIdx`, where `levelListIdx` ranges from 0 to 62, inclusive.

Table 9-34 – Mapping of scanning position to `ctxIdxInc` for `ctxBlockCat == 5`

levelListIdx	ctxIdxInc for significant_coeff_flag (frame coded macroblocks)	ctxIdxInc for significant_coeff_flag (field coded macroblocks)	ctxIdxInc for last_significant_coeff_flag	levelListIdx	ctxIdxInc for significant_coeff_flag (frame coded macroblocks)	ctxIdxInc for significant_coeff_flag (field coded macroblocks)	ctxIdxInc for last_significant_coeff_flag
0	0	0	0	32	7	9	3
1	1	1	1	33	6	9	3
2	2	1	1	34	11	10	3
3	3	2	1	35	12	10	3
4	4	2	1	36	13	8	3

24	7	9	2	56	11	10	7

levelIdx	ctxIdxInc for significant_coeff_flag (frame coded macroblocks)	ctxIdxInc for significant_coeff_flag (field coded macroblocks)	ctxIdxInc for last_significant_coeff_flag	levelIdx	ctxIdxInc for significant_coeff_flag (frame coded macroblocks)	ctxIdxInc for significant_coeff_flag (field coded macroblocks)	ctxIdxInc for last_significant_coeff_flag
25	7	9	2	57	12	10	7
26	8	10	2	58	13	14	7
27	9	10	2	59	11	14	7
28	10	8	2	60	14	14	8
29	9	11	2	61	10	14	8
30	8	12	2	62	12	14	8
31	7	11	2				

Let numDecodAbsLevelEq1 denotes the accumulated number of decoded transform coefficient levels with absolute value equal to 1, and let numDecodAbsLevelGt1 denotes the accumulated number of decoded transform coefficient levels with absolute value greater than 1. Both numbers are related to the same transform coefficient block, where the current decoding process takes place. Then, for decoding of coeff_abs_level_minus1, ctxIdxInc for coeff_abs_level_minus1 is specified depending on binIdx as follows.

- If binIdx is equal to 0, ctxIdxInc is derived by

$$\text{ctxIdxInc} = ((\text{numDecodAbsLevelGt1} \neq 0) ? 0 : \text{Min}(4, 1 + \text{numDecodAbsLevelEq1})) \quad (9-17)$$

- Otherwise (binIdx is greater than 0), ctxIdxInc is derived by

$$\text{ctxIdxInc} = 5 + \text{Min}(4 - (\text{ctxBlockCat} == 3), \text{numDecodAbsLevelGt1}) \quad (9-18)$$

9.3.3.2 Arithmetic decoding process

Inputs to this process are the bypassFlag, ctxIdx as derived in subclause 9.3.3.1, and the state variables codIRange and codIOffset of the arithmetic decoding engine.

Output of this process is the value of the bin.

Figure 9-2 illustrates the whole arithmetic decoding process for a single bin. For decoding the value of a bin, the context index ctxIdx is passed to the arithmetic decoding process DecodeBin(ctxIdx), which is specified as follows.

- If bypassFlag is equal to 1, DecodeBypass() as specified in subclause 9.3.3.2.3 is invoked.
- Otherwise, if bypassFlag is equal to 0 and ctxIdx is equal to 276, DecodeTerminate() as specified in subclause 9.3.3.2.4 is invoked.
- Otherwise (bypassFlag is equal to 0 and ctxIdx is not equal to 276), DecodeDecision() as specified in subclause 9.3.3.2.1 is applied.

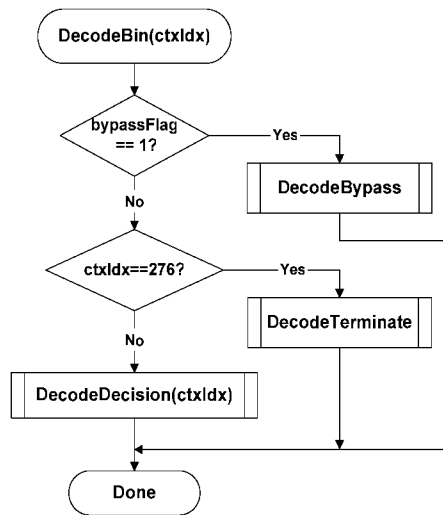

Figure 9-2 – Overview of the arithmetic decoding process for a single bin (informative)

NOTE – Arithmetic coding is based on the principle of recursive interval subdivision. Given a probability estimation $p(0)$ and $p(1) = 1 - p(0)$ of a binary decision $(0, 1)$, an initially given code sub-interval with the range codIRange will be subdivided into two sub-intervals having range $p(0) * \text{codIRange}$ and $\text{codIRange} - p(0) * \text{codIRange}$, respectively. Depending on the decision, which has been observed, the corresponding sub-interval will be chosen as the new code interval, and a binary code string pointing into that interval will represent the sequence of observed binary decisions. It is useful to distinguish between the most probable symbol (MPS) and the least probable symbol (LPS), so that binary decisions have to be identified as either MPS or LPS, rather than 0 or 1. Given this terminology, each context is specified by the probability p_{LPS} of the LPS and the value of MPS (valMPS), which is either 0 or 1.

The arithmetic core engine in this Recommendation | International Standard has three distinct properties:

- The probability estimation is performed by means of a finite-state machine with a table-based transition process between 64 different representative probability states $\{p_{\text{LPS}}(p\text{StateIdx}) \mid 0 \leq p\text{StateIdx} < 64\}$ for the LPS probability p_{LPS} . The numbering of the states is arranged in such a way that the probability state with index $p\text{StateIdx} = 0$ corresponds to an LPS probability value of 0.5, with decreasing LPS probability towards higher state indices.
- The range codIRange representing the state of the coding engine is quantised to a small set $\{Q_1, \dots, Q_4\}$ of pre-set quantisation values prior to the calculation of the new interval range. Storing a table containing all 64×4 pre-computed product values of $Q_i * p_{\text{LPS}}(p\text{StateIdx})$ allows a multiplication-free approximation of the product $\text{codIRange} * p_{\text{LPS}}(p\text{StateIdx})$.
- For syntax elements or parts thereof for which an approximately uniform probability distribution is assumed to be given a separate simplified encoding and decoding bypass process is used.

9.3.3.2.1 Arithmetic decoding process for a binary decision

Inputs to this process are ctxIdx , codIRange , and codIOffset .

Outputs of this process are the decoded value binVal , and the updated variables codIRange and codIOffset .

Figure 9-3 shows the flowchart for decoding a single decision (DecodeDecision).

1. The value of the variable codIRangeLPS is derived as follows.
 - Given the current value of codIRange , the variable qCodIRangeIdx is derived by

$$\text{qCodIRangeIdx} = (\text{codIRange} \gg 6) \& 0x03 \quad (9-19)$$

- Given qCodIRangeIdx and $p\text{StateIdx}$ associated with ctxIdx , the value of the variable rangeTabLPS as specified in Table 9-35 is assigned to codIRangeLPS :

$$\text{codIRangeLPS} = \text{rangeTabLPS}[p\text{StateIdx}][\text{qCodIRangeIdx}] \quad (9-20)$$

2. The variable `codIRange` is set equal to `codIRange – codIRangeLPS` and the following applies.
 - If `codIOffset` is greater than or equal to `codIRange`, the variable `binVal` is set equal to $1 - \text{valMPS}$, `codIOffset` is decremented by `codIRange`, and `codIRange` is set equal to `codIRangeLPS`.
 - Otherwise, the variable `binVal` is set equal to `valMPS`.

Given the value of `binVal`, the state transition is performed as specified in subclause 9.3.3.2.1.1. Depending on the current value of `codIRange`, renormalization is performed as specified in subclause 9.3.3.2.2.

9.3.3.2.1.1 State transition process

Inputs to this process are the current `pStateIdx`, the decoded value `binVal` and `valMPS` values of the context variable associated with `ctxIdx`.

Outputs of this process are the updated `pStateIdx` and `valMPS` of the context variable associated with `ctxIdx`.

Depending on the decoded value `binVal`, the update of the two variables `pStateIdx` and `valMPS` associated with `ctxIdx` is derived as follows:

```

if( binVal == valMPS )
    pStateIdx = transIdxMPS( pStateIdx )
else {
    if( pStateIdx == 0 )
        valMPS = 1 - valMPS
    pStateIdx = transIdxLPS( pStateIdx )
}
  
```

(9-21)

Table 9-36 specifies the transition rules `transIdxMPS()` and `transIdxLPS()` after decoding the value of `valMPS` and $1 - \text{valMPS}$, respectively.

9.3.3.2.2 Renormalization process in the arithmetic decoding engine

Inputs to this process are bits from slice data and the variables codIRange and codIOffset.

Outputs of this process are the updated variables codIRange and codIOffset.

A flowchart of the renormalization is shown in Figure 9-4. The current value of codIRange is first compared to 0x0100 and further steps are specified as follows.

- If codIRange is greater than or equal to 0x0100, no renormalization is needed and the RenormD process is finished;
- Otherwise (codIRange is less than 0x0100), the renormalization loop is entered. Within this loop, the value of codIRange is doubled, i.e., left-shifted by 1 and a single bit is shifted into codIOffset by using read_bits(1).

The bitstream shall not contain data that results in a value of codIOffset being greater than or equal to codIRange upon completion of this process.

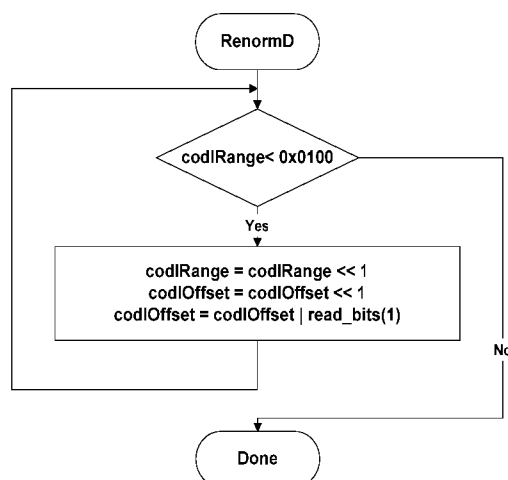

Figure 9-4 – Flowchart of renormalization

9.3.3.2.3 Bypass decoding process for binary decisions

Inputs to this process are bits from slice data and the variables `codIRange` and `codIOffset`.

Outputs of this process are the updated variable `codIOffset` and the decoded value `binVal`.

The bypass decoding process is invoked when `bypassFlag` is equal to 1. Figure 9-5 shows a flowchart of the corresponding process.

First, the value of `codIOffset` is doubled, i.e., left-shifted by 1 and a single bit is shifted into `codIOffset` by using `read_bits(1)`. Then, the value of `codIOffset` is compared to the value of `codIRange` and further steps are specified as follows.

- If `codIOffset` is greater than or equal to `codIRange`, the variable `binVal` is set equal to 1 and `codIOffset` is decremented by `codIRange`.
- Otherwise (`codIOffset` is less than `codIRange`), the variable `binVal` is set equal to 0.

The bitstream shall not contain data that results in a value of `codIOffset` being greater than or equal to `codIRange` upon completion of this process.

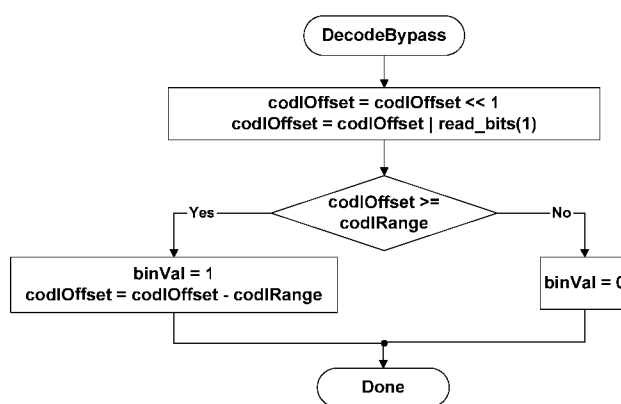

Figure 9-5 – Flowchart of bypass decoding process

9.3.3.2.4 Decoding process for binary decisions before termination

Inputs to this process are bits from slice data and the variables `codIRange` and `codIOffset`.

Outputs of this process are the updated variables `codIRange` and `codIOffset`, and the decoded value `binVal`.

This special decoding routine applies to decoding of `end_of_slice_flag` and of the bin indicating the `L_PCM` mode corresponding to `ctxIdx` equal to 276. Figure 9-6 shows the flowchart of the corresponding decoding process, which is specified as follows.

First, the value of `codIRange` is decremented by 2. Then, the value of `codIOffset` is compared to the value of `codIRange` and further steps are specified as follows.

- If `codIOffset` is greater than or equal to `codIRange`, the variable `binVal` is set equal to 1, no renormalization is carried out, and CABAC decoding is terminated. The last bit inserted in register `codIOffset` is equal to 1. When decoding `end_of_slice_flag`, this last bit inserted in register `codIOffset` is interpreted as `rbsp_stop_one_bit`.
- Otherwise (`codIOffset` is less than `codIRange`), the variable `binVal` is set equal to 0 and renormalization is performed as specified in subclause 9.3.3.2.2.

NOTE – This procedure may also be implemented using `DecodeDecision(ctxIdx)` with `ctxIdx = 276`. In the case where the decoded value is equal to 1, seven more bits would be read by `DecodeDecision(ctxIdx)` and a decoding process would have to adjust its bitstream pointer accordingly to properly decode following syntax elements.

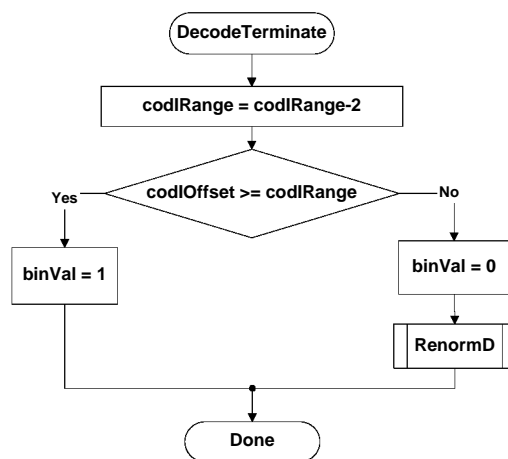

Figure 9-6 – Flowchart of decoding a decision before termination

9.3.4 Arithmetic encoding process (informative)

This subclause does not form an integral part of this Recommendation | International Standard.

Inputs to this process are decisions that are to be encoded and written.

Outputs of this process are bits that are written to the RBSP.

This informative subclause describes an arithmetic encoding engine that matches the arithmetic decoding engine described in subclause 9.3.3.2. The encoding engine is essentially symmetric with the decoding engine, i.e., procedures are called in the same order. The following procedures are described in this section: InitEncoder, EncodeDecision, EncodeBypass, EncodeTerminate, which correspond to InitDecoder, DecodeDecision, DecodeBypass, and DecodeTerminate, respectively. The state of the arithmetic encoding engine is represented by a value of the variable codILow pointing to the lower end of a sub-interval and a value of the variable codIRange specifying the corresponding range of that sub-interval.

9.3.4.1 Initialisation process for the arithmetic encoding engine (informative)

This subclause does not form an integral part of this Recommendation | International Standard.

This process is invoked before encoding the first macroblock of a slice, and after encoding any pcm_alignment_zero_bit and all pcm_sample_luma and pcm_sample_chroma data for a macroblock of type I_PCM.

Outputs of this process are the values codILow, codIRange, firstBitFlag, bitsOutstanding, and symCnt of the arithmetic encoding engine.

In the initialisation procedure of the encoder, codILow is set equal to 0, and codIRange is set equal to 0x01FE. Furthermore, a firstBitFlag is set equal to 1, and bitsOutstanding and symCnt counters are set equal to 0.

NOTE – The minimum register precision required for codILow is 10 bits and for CodIRange is 9 bits. The precision required for the counters bitsOutstanding and symCnt should be sufficiently large to prevent overflow of the related registers. When MaxBinCountInSlice denotes the maximum total number of binary decisions to encode in one slice, the minimum register precision required for the variables bitsOutstanding and symCnt is given by $\text{Ceil}(\text{Log}_2(\text{MaxBinCountInSlice} + 1))$.

9.3.4.2 Encoding process for a binary decision (informative)

This subclause does not form an integral part of this Recommendation | International Standard.

Inputs to this process are the context index ctxIdx, the value of binVal to be encoded, and the variables codIRange, codILow and symCnt.

Outputs of this process are the variables codIRange, codILow, and symCnt.

Figure 9-7 shows the flowchart for encoding a single decision. In a first step, the variable codIRangeLPS is derived as follows.

Given the current value of codIRange, codIRange is mapped to the index qCodIRangeIdx of a quantised value of codIRange by using Equation 9-19. The value of qCodIRangeIdx and the value of pStateIdx associated with ctxIdx are

used to determine the value of the variable rangeTabLPS as specified in Table 9-35, which is assigned to codIRangeLPS. The value of codIRange – codIRangeLPS is assigned to codIRange.

In a second step, the value of binVal is compared to valMPS associated with ctxIdx. When binVal is different from valMPS, codIRange is added to codILow and codIRange is set equal to the value codIRangeLPS. Given the encoded decision, the state transition is performed as specified in subclause 9.3.3.2.1.1. Depending on the current value of codIRange, renormalization is performed as specified in subclause 9.3.4.3. Finally, the variable symCnt is incremented by 1.

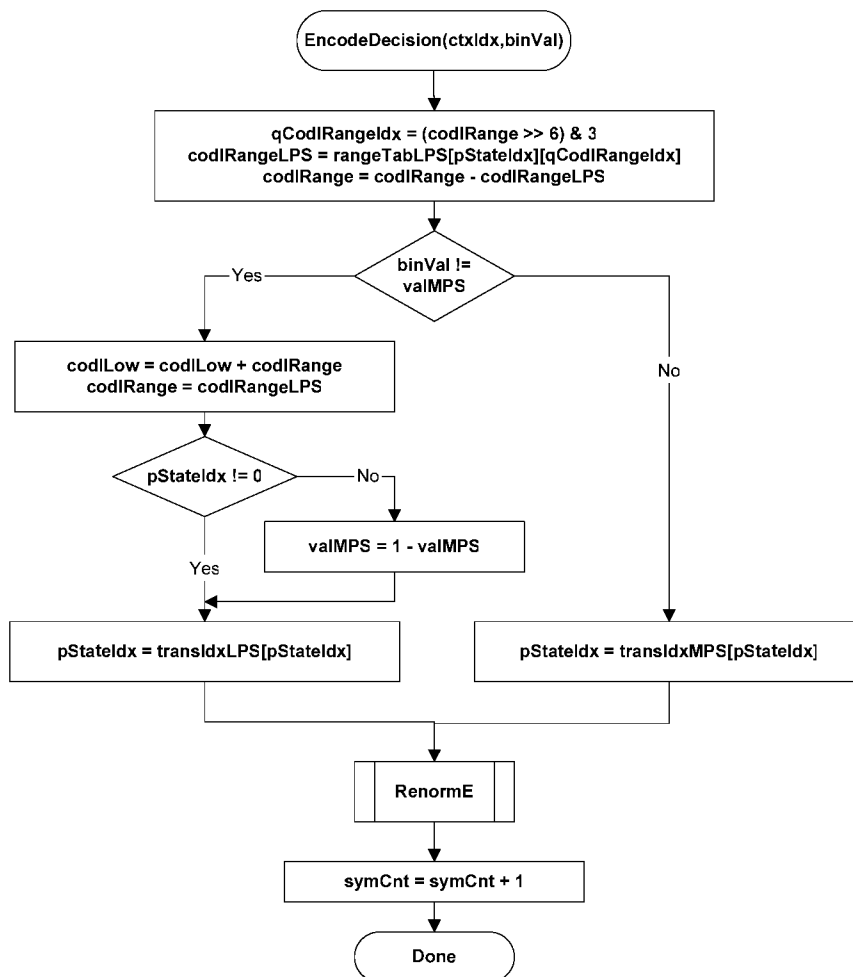

Figure 9-7 – Flowchart for encoding a decision

9.3.4.3 Renormalization process in the arithmetic encoding engine (informative)

This subclause does not form an integral part of this Recommendation | International Standard.

Inputs to this process are the variables codIRange, codILow, firstBitFlag, and bitsOutstanding.

Outputs of this process are zero or more bits written to the RBSP and the updated variables codIRange, codILow, firstBitFlag, and bitsOutstanding.

Renormalization is illustrated in Figure 9-8.

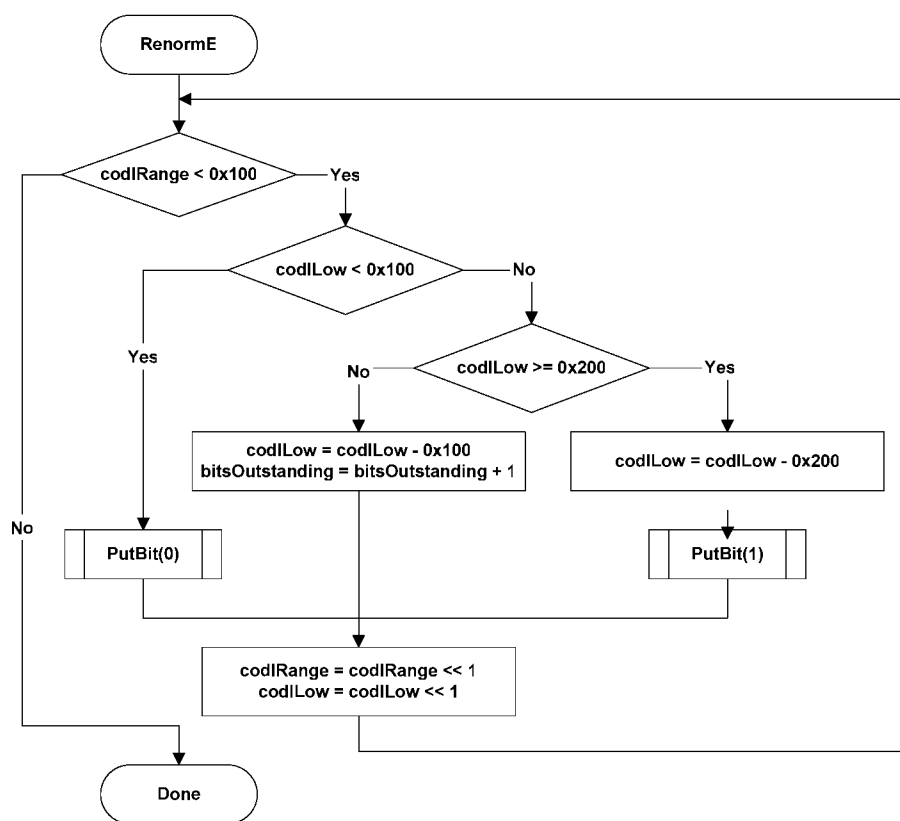

Figure 9-8 – Flowchart of renormalization in the encoder

The PutBit() procedure described in Figure 9-9 provides carry over control. It uses the function WriteBits(B, N) that writes N bits with value B to the bitstream and advances the bitstream pointer by N bit positions. This function assumes the existence of a bitstream pointer with an indication of the position of the next bit to be written to the bitstream by the encoding process.

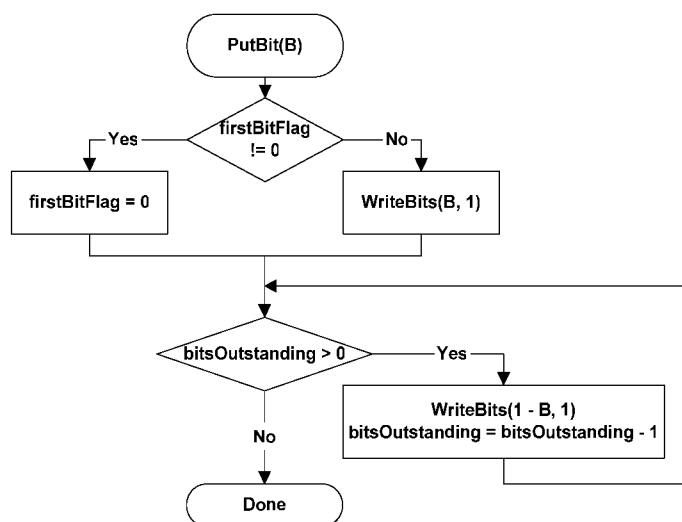

Figure 9-9 – Flowchart of PutBit(B)

9.3.4.4 Bypass encoding process for binary decisions (informative)

This subclause does not form an integral part of this Recommendation | International Standard.

Inputs to this process are the variables `binVal`, `codILow`, `codIRange`, `bitsOutstanding`, and `symCnt`.

Output of this process is a bit written to the RBSP and the updated variables `codILow`, `bitsOutstanding`, and `symCnt`.

This encoding process applies to all binary decisions with `bypassFlag` equal to 1. Renormalization is included in the specification of this process as given in Figure 9-10.

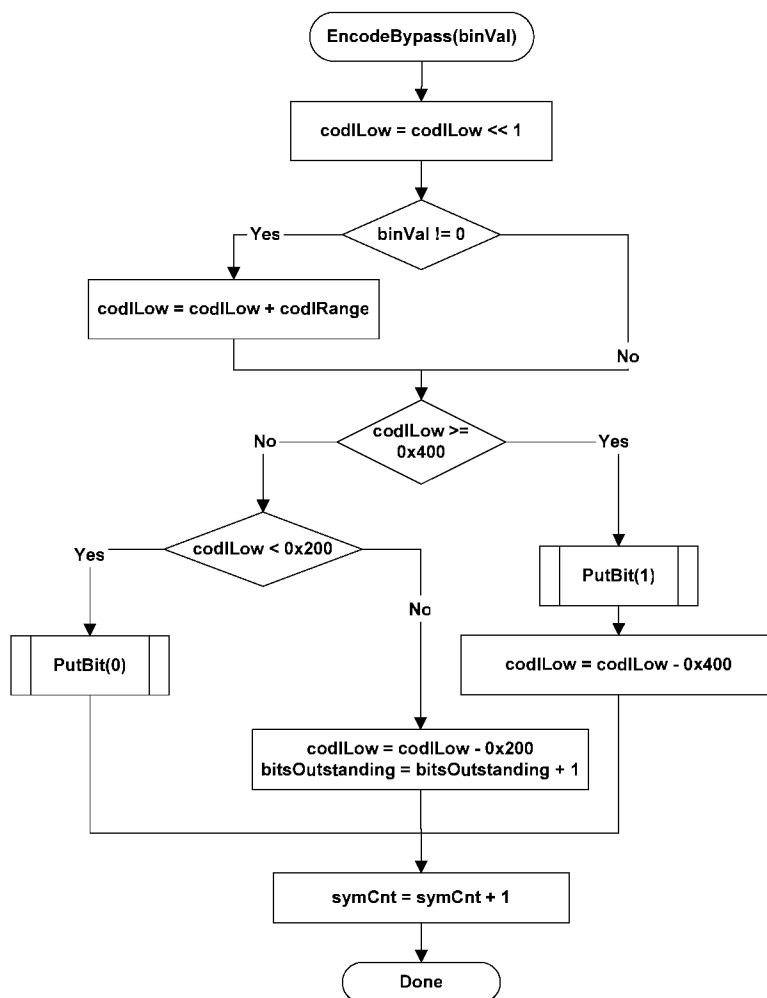

Figure 9-10 – Flowchart of encoding bypass

9.3.4.5 Encoding process for a binary decision before termination (informative)

This subclause does not form an integral part of this Recommendation | International Standard.

Inputs to this process are the variables `binVal`, `codIRange`, `codILow`, `bitsOutstanding`, and `symCnt`.

Outputs of this process are zero or more bits written to the RBSP and the updated variables `codILow`, `codIRange`, `bitsOutstanding`, and `symCnt`.

This encoding routine shown in Figure 9-11 applies to encoding of the `end_of_slice_flag` and of the bin indicating the `L_PCM mb_type` both associated with `ctxIdx` equal to 276.

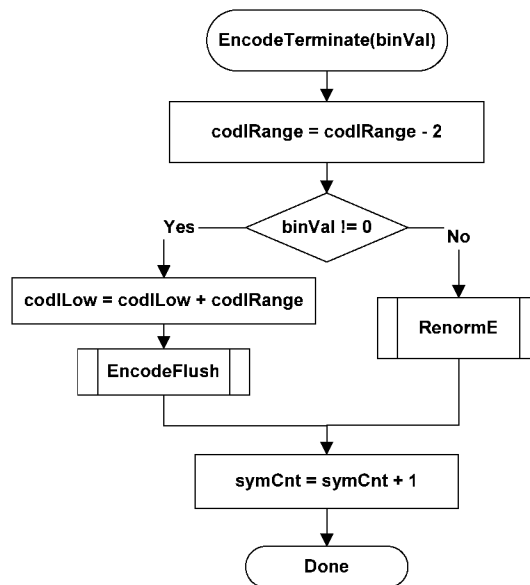

Figure 9-11 – Flowchart of encoding a decision before termination

When the value of binVal to encode is equal to 1, CABAC encoding is terminated and the flushing procedure shown in Figure 9-12 is applied. In this flushing procedure, the last bit written by WriteBits(B, N) is equal to 1. When encoding end_of_slice_flag, this last bit is interpreted as the rbsp_stop_one_bit.

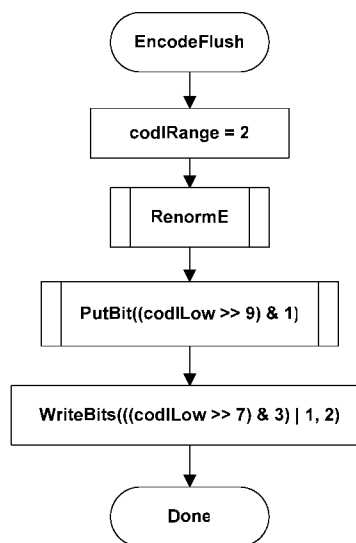

Figure 9-12 – Flowchart of flushing at termination

9.3.4.6 Byte stuffing process (informative)

This subclause does not form an integral part of this Recommendation | International Standard.

This process is invoked after encoding the last macroblock of the last slice of a picture and after encapsulation.

Inputs to this process are the number of bytes NumBytesInVclNALunits of all VCL NAL units of a picture, the number of macroblocks PicSizeInMbs in the picture, and the number of binary symbols BinCountsInNALunits resulting from encoding the contents of all VCL NAL units of the picture.

Outputs of this process are zero or more bytes appended to the NAL unit.

Let the variable k be set equal to $\text{Ceil}((\text{Ceil}(3 * (32 * \text{BinCountsInNALunits} - \text{RawMbBits} * \text{PicSizeInMbs}) \div 1024) - \text{NumBytesInVclNALunits}) \div 3)$. Depending on the variable k the following applies.

- If k is less than or equal to 0, no `cabac_zero_word` is appended to the NAL unit.
- Otherwise (k is greater than 0), the 3-byte sequence `0x000003` is appended k times to the NAL unit after encapsulation, where the first two bytes `0x0000` represent a `cabac_zero_word` and the third byte `0x03` represents an `emulation_prevention_three_byte`.

Annex A

Profiles and levels

(This annex forms an integral part of this Recommendation | International Standard)

Profiles and levels specify restrictions on bitstreams and hence limits on the capabilities needed to decode the bitstreams. Profiles and levels may also be used to indicate interoperability points between individual decoder implementations.

NOTE 1 – This Recommendation | International Standard does not include individually selectable “options” at the decoder, as this would increase interoperability difficulties.

Each profile specifies a subset of algorithmic features and limits that shall be supported by all decoders conforming to that profile.

NOTE 2 – Encoders are not required to make use of any particular subset of features supported in a profile.

Each level specifies a set of limits on the values that may be taken by the syntax elements of this Recommendation | International Standard. The same set of level definitions is used with all profiles, but individual implementations may support a different level for each supported profile. For any given profile, levels generally correspond to decoder processing load and memory capability.

A.1 Requirements on video decoder capability

Capabilities of video decoders conforming to this Recommendation | International Standard are specified in terms of the ability to decode video streams conforming to the constraints of profiles and levels specified in this Annex. For each such profile, the level supported for that profile shall also be expressed.

Specific values are specified in this annex for the syntax elements `profile_idc` and `level_idc`. All other values of `profile_idc` and `level_idc` are reserved for future use by ITU-T | ISO/IEC.

NOTE – Decoders should not infer that when a reserved value of `profile_idc` or `level_idc` falls between the values specified in this Recommendation | International Standard that this indicates intermediate capabilities between the specified profiles or levels, as there are no restrictions on the method to be chosen by ITU-T | ISO/IEC for the use of such future reserved values.

A.2 Profiles

A.2.1 Baseline profile

Bitstreams conforming to the Baseline profile shall obey the following constraints:

- Only I and P slice types may be present.
- NAL unit streams shall not contain `nal_unit_type` values in the range of 2 to 4, inclusive.
- Sequence parameter sets shall have `frame_mbs_only_flag` equal to 1.
- The syntax elements `chroma_format_idc`, `bit_depth_luma_minus8`, `bit_depth_chroma_minus8`, `qpprime_y_zero_transform_bypass_flag`, and `seq_scaling_matrix_present_flag` shall not be present in sequence parameter sets.
- Picture parameter sets shall have `weighted_pred_flag` and `weighted_bipred_idc` both equal to 0.
- Picture parameter sets shall have `entropy_coding_mode_flag` equal to 0.
- Picture parameter sets shall have `num_slice_groups_minus1` in the range of 0 to 7, inclusive.
- The syntax elements `transform_8x8_mode_flag`, `pic_scaling_matrix_present_flag`, and `second_chroma_qp_index_offset` shall not be present in picture parameter sets.
- The syntax element `level_prefix` shall not be greater than 15.
- The level constraints specified for the Baseline profile in subclause A.3 shall be fulfilled.

Conformance of a bitstream to the Baseline profile is specified by `profile_idc` being equal to 66.

Decoders conforming to the Baseline profile at a specific level shall be capable of decoding all bitstreams in which `profile_idc` is equal to 66 or `constraint_set0_flag` is equal to 1 and in which `level_idc` and `constraint_set3_flag` represent a level less than or equal to the specified level.

A.2.2 Main profile

Bitstreams conforming to the Main profile shall obey the following constraints:

- Only I, P, and B slice types may be present.
- NAL unit streams shall not contain `nal_unit_type` values in the range of 2 to 4, inclusive.
- Arbitrary slice order is not allowed.
- The syntax elements `chroma_format_idc`, `bit_depth_luma_minus8`, `bit_depth_chroma_minus8`, `qp_prime_y_zero_transform_bypass_flag`, and `seq_scaling_matrix_present_flag` shall not be present in sequence parameter sets.
- Picture parameter sets shall have `num_slice_groups_minus1` equal to 0 only.
- Picture parameter sets shall have `redundant_pic_cnt_present_flag` equal to 0 only.
- The syntax elements `transform_8x8_mode_flag`, `pic_scaling_matrix_present_flag`, and `second_chroma_qp_index_offset` shall not be present in picture parameter sets.
- The syntax element `level_prefix` shall not be greater than 15 (when present).
- The level constraints specified for the Main profile in subclause A.3 shall be fulfilled.

Conformance of a bitstream to the Main profile is specified by `profile_idc` being equal to 77.

Decoders conforming to the Main profile at a specified level shall be capable of decoding all bitstreams in which `profile_idc` is equal to 77 or `constraint_set1_flag` is equal to 1 and in which `level_idc` and `constraint_set3_flag` represent a level less than or equal to the specified level.

A.2.3 Extended profile

Bitstreams conforming to the Extended profile shall obey the following constraints:

- Sequence parameter sets shall have `direct_8x8_inference_flag` equal to 1.
- The syntax elements `chroma_format_idc`, `bit_depth_luma_minus8`, `bit_depth_chroma_minus8`, `qp_prime_y_zero_transform_bypass_flag`, and `seq_scaling_matrix_present_flag` shall not be present in sequence parameter sets.
- Picture parameter sets shall have `entropy_coding_mode_flag` equal to 0.
- Picture parameter sets shall have `num_slice_groups_minus1` in the range of 0 to 7, inclusive.
- The syntax elements `transform_8x8_mode_flag`, `pic_scaling_matrix_present_flag`, and `second_chroma_qp_index_offset` shall not be present in picture parameter sets.
- The syntax element `level_prefix` shall not be greater than 15 (when present).
- The level constraints specified for the Extended profile in subclause A.3 shall be fulfilled.

Conformance of a bitstream to the Extended profile is specified by `profile_idc` being equal to 88.

Decoders conforming to the Extended profile at a specified level shall be capable of decoding all bitstreams in which `profile_idc` is equal to 88 or `constraint_set2_flag` is equal to 1 and in which `level_idc` represents a level less than or equal to specified level.

Decoders conforming to the Extended profile at a specified level shall also be capable of decoding all bitstreams in which `profile_idc` is equal to 66 or `constraint_set0_flag` is equal to 1, in which `level_idc` and `constraint_set3_flag` represent a level less than or equal to the specified level.

A.2.4 High profile

Bitstreams conforming to the High profile shall obey the following constraints:

- Only I, P, and B slice types may be present.
- NAL unit streams shall not contain `nal_unit_type` values in the range of 2 to 4, inclusive.
- Arbitrary slice order is not allowed.
- Picture parameter sets shall have `num_slice_groups_minus1` equal to 0 only.
- Picture parameter sets shall have `redundant_pic_cnt_present_flag` equal to 0 only.
- Sequence parameter sets shall have `chroma_format_idc` in the range of 0 to 1 inclusive.
- Sequence parameter sets shall have `bit_depth_luma_minus8` equal to 0 only.
- Sequence parameter sets shall have `bit_depth_chroma_minus8` equal to 0 only.

- Sequence parameter sets shall have `qpprime_y_zero_transform_bypass_flag` equal to 0 only.
- The level constraints specified for the High profile in subclause A.3 shall be fulfilled.

Conformance of a bitstream to the High profile is specified by `profile_idc` being equal to 100. Decoders conforming to the High profile at a specific level shall be capable of decoding all bitstreams in which `level_idc` and `constraint_set3_flag` represents a level less than or equal to the specified level and either or both of the following conditions are true:

- `profile_idc` is equal to 77 or 100, or
- `constraint_set1_flag` is equal to 1.

A.2.5 High 10 profile

Bitstreams conforming to the High 10 profile shall obey the following constraints:

- Only I, P, and B slice types may be present.
- NAL unit streams shall not contain `nal_unit_type` values in the range of 2 to 4, inclusive.
- Arbitrary slice order is not allowed.
- Picture parameter sets shall have `num_slice_groups_minus1` equal to 0 only.
- Picture parameter sets shall have `redundant_pic_cnt_present_flag` equal to 0 only.
- Sequence parameter sets shall have `chroma_format_idc` in the range of 0 to 1 inclusive.
- Sequence parameter sets shall have `bit_depth_luma_minus8` in the range of 0 to 2 inclusive.
- Sequence parameter sets shall have `bit_depth_chroma_minus8` in the range of 0 to 2 inclusive.
- Sequence parameter sets shall have `qpprime_y_zero_transform_bypass_flag` equal to 0 only.
- The level constraints specified for the High 10 profile in subclause A.3 shall be fulfilled.

Conformance of a bitstream to the High 10 profile is specified by `profile_idc` being equal to 110. Decoders conforming to the High 10 profile at a specific level shall be capable of decoding all bitstreams in which `level_idc` and `constraint_set3_flag` represent a level less than or equal to the specified level and either or both of the following conditions are true:

- `profile_idc` is equal to 77, 100, or 110, or
- `constraint_set1_flag` is equal to 1.

A.2.6 High 4:2:2 profile

Bitstreams conforming to the High 4:2:2 profile shall obey the following constraints:

- Only I, P, and B slice types may be present.
- NAL unit streams shall not contain `nal_unit_type` values in the range of 2 to 4, inclusive.
- Arbitrary slice order is not allowed.
- Picture parameter sets shall have `num_slice_groups_minus1` equal to 0 only.
- Picture parameter sets shall have `redundant_pic_cnt_present_flag` equal to 0 only.
- Sequence parameter sets shall have `chroma_format_idc` in the range of 0 to 2 inclusive
- Sequence parameter sets shall have `bit_depth_luma_minus8` in the range of 0 to 2 inclusive.
- Sequence parameter sets shall have `bit_depth_chroma_minus8` in the range of 0 to 2 inclusive.
- Sequence parameter sets shall have `qpprime_y_zero_transform_bypass_flag` equal to 0 only.
- The level constraints specified for the High 4:2:2 profile in subclause A.3 shall be fulfilled.

Conformance of a bitstream to the High 4:2:2 profile is specified by `profile_idc` being equal to 122. Decoders conforming to the High 4:2:2 profile at a specific level shall be capable of decoding all bitstreams in which `level_idc` and `constraint_set3_flag` represents a level less than or equal to the specified level and either or both of the following conditions are true:

- `profile_idc` is equal to 77, 100, 110, or 122, or
- `constraint_set1_flag` is equal to 1.

A.2.7 High 4:4:4 profile

Bitstreams conforming to the High 4:4:4 profile shall obey the following constraints:

- Only I, P, and B slice types may be present.
- NAL unit streams shall not contain nal_unit_type values in the range of 2 to 4, inclusive.
- Arbitrary slice order is not allowed.
- Picture parameter sets shall have num_slice_groups_minus1 equal to 0 only.
- Picture parameter sets shall have redundant_pic_cnt_present_flag equal to 0 only.
- Sequence parameter sets shall have bit_depth_luma_minus8 in the range of 0 to 4 inclusive.
- Sequence parameter sets shall have bit_depth_chroma_minus8 in the range of 0 to 4 inclusive.
- The level constraints specified for the High 4:4:4 profile in subclause A.3 shall be fulfilled.

Conformance of a bitstream to the High 4:4:4 profile is specified by profile_idc being equal to 144. Decoders conforming to the High 4:4:4 profile at a specific level shall be capable of decoding all bitstreams in which level_idc and constraint_set3_flag represent a level less than or equal to the specified level and either or both of the following conditions are true:

- profile_idc is equal to 77, 100, 110, 122, or 144, or
- constraint_set1_flag is equal to 1.

A.3 Levels

The following is specified for expressing the constraints in this Annex.

- Let access unit n be the n-th access unit in decoding order with the first access unit being access unit 0.
- Let picture n be the primary coded picture or the corresponding decoded picture of access unit n.

A.3.1 Level limits common to the Baseline, Main, and Extended profiles

Let the variable fR be derived as follows.

- If picture n is a frame, fR is set equal to $1 \div 172$.
- Otherwise (picture n is a field), fR is set equal to $1 \div (172 * 2)$.

Bitstreams conforming to the Baseline, Main, or Extended profiles at a specified level shall obey the following constraints:

- a) The nominal removal time of access unit n (with $n > 0$) from the CPB as specified in subclause C.1.2, satisfies the constraint that $t_{r,n}(n) - t_r(n-1)$ is greater than or equal to $\text{Max}(\text{PicSizeInMbs} \div \text{MaxMBPS}, fR)$, where MaxMBPS is the value specified in Table A-1 that applies to picture n – 1, and PicSizeInMbs is the number of macroblocks in picture n – 1.
- b) The difference between consecutive output times of pictures from the DPB as specified in subclause C.2.2, satisfies the constraint that $\Delta t_{o,dpb}(n) \geq \text{Max}(\text{PicSizeInMbs} \div \text{MaxMBPS}, fR)$, where MaxMBPS is the value specified in Table A-1 for picture n, and PicSizeInMbs is the number of macroblocks of picture n, provided that picture n is a picture that is output and is not the last picture of the bitstream that is output.
- c) The sum of the NumBytesInNALunit variables for access unit 0 is less than or equal to $384 * (\text{PicSizeInMbs} + \text{MaxMBPS} * (t_r(0) - t_{r,n}(0))) \div \text{MinCR}$, where MaxMBPS and MinCR are the values specified in Table A-1 that apply to picture 0 and PicSizeInMbs is the number of macroblocks in picture 0.
- d) The sum of the NumBytesInNALunit variables for access unit n (with $n > 0$) is less than or equal to $384 * \text{MaxMBPS} * (t_r(n) - t_r(n-1)) \div \text{MinCR}$, where MaxMBPS and MinCR are the values specified in Table A-1 that apply to picture n.
- e) $\text{PicWidthInMbs} * \text{FrameHeightInMbs} \leq \text{MaxFS}$, where MaxFS is specified in Table A-1
- f) $\text{PicWidthInMbs} \leq \text{Sqrt}(\text{MaxFS} * 8)$
- g) $\text{FrameHeightInMbs} \leq \text{Sqrt}(\text{MaxFS} * 8)$
- h) $\text{max_dec_frame_buffering} \leq \text{MaxDpbSize}$, where MaxDpbSize is equal to $\text{Min}(1024 * \text{MaxDPB} / (\text{PicWidthInMbs} * \text{FrameHeightInMbs} * 384), 16)$ and MaxDPB is given in Table A-1 in units of 1024 bytes.

- i) For the VCL HRD parameters, $\text{BitRate}[\text{SchedSelIdx}] \leq 1000 * \text{MaxBR}$ and $\text{CpbSize}[\text{SchedSelIdx}] \leq 1000 * \text{MaxCPB}$ for at least one value of SchedSelIdx, where $\text{BitRate}[\text{SchedSelIdx}]$ is given by Equation E-37 and $\text{CpbSize}[\text{SchedSelIdx}]$ is given by Equation E-38 when `vcl_hrd_parameters_present_flag` is equal to 1. MaxBR and MaxCPB are specified in Table A-1 in units of 1000 bits/s and 1000 bits, respectively. The bitstream shall satisfy these conditions for at least one value of SchedSelIdx in the range 0 to `cpb_cnt_minus1`, inclusive.
- j) For the NAL HRD parameters, $\text{BitRate}[\text{SchedSelIdx}] \leq 1200 * \text{MaxBR}$ and $\text{CpbSize}[\text{SchedSelIdx}] \leq 1200 * \text{MaxCPB}$ for at least one value of SchedSelIdx, where $\text{BitRate}[\text{SchedSelIdx}]$ is given by Equation E-37 and $\text{CpbSize}[\text{SchedSelIdx}]$ is given by Equation E-38 when `nal_hrd_parameters_present_flag` equal to 1. MaxBR and MaxCPB are specified in Table A-1 in units of 1200 bits/s and 1200 bits, respectively. The bitstream shall satisfy these conditions for at least one value of SchedSelIdx in the range 0 to `cpb_cnt_minus1`.
- k) Vertical motion vector component range luma motion vectors does not exceed MaxVmvR in units of luma frame samples, where MaxVmvR is specified in Table A-1

NOTE 1 – When `chroma_format_idc` is equal to 1 and the current macroblock is a field macroblock, the motion vector component range for chroma motion vectors may exceed MaxVmvR in units of luma frame samples, due to the method of deriving chroma motion vectors as specified in subclause 8.4.1.4.
- l) Horizontal motion vector range does not exceed the range of -2048 to 2047.75, inclusive, in units of luma samples
- m) Number of motion vectors per two consecutive macroblocks in decoding order (also applying to the total from the last macroblock of a slice and the first macroblock of the next slice in decoding order, and in particular also applying to the total from the last macroblock of the last slice of a picture and the first macroblock of the first slice of the next picture in decoding order) does not exceed MaxMvsPer2Mb, where MaxMvsPer2Mb is specified in Table A-1. The number of motion vectors for each macroblock is the value of the variable MvCnt after the completion of the intra or inter prediction process for the macroblock.
- n) Number of bits of `macroblock_layer()` data for any macroblock is not greater than 3200. Depending on `entropy_coding_mode_flag`, the bits of `macroblock_layer()` data are counted as follows.
 - If `entropy_coding_mode_flag` is equal to 0, the number of bits of `macroblock_layer()` data is given by the number of bits in the `macroblock_layer()` syntax structure for a macroblock.
 - Otherwise (`entropy_coding_mode_flag` is equal to 1), the number of bits of `macroblock_layer()` data for a macroblock is given by the number of times `read_bits(1)` is called in subclauses 9.3.3.2.2 and 9.3.3.2.3 when parsing the `macroblock_layer()` associated with the macroblock.

Table A-1 specifies the limits for each level. Entries marked "-" in Table A-1 denote the absence of a corresponding limit. For purposes of comparison of level capabilities, a level shall be considered to be a lower (higher) level than some other level if the level appears nearer to the top (bottom) row of Table A-1 than the other level.

A level to which the bitstream conforms shall be indicated by the syntax elements `level_idc` and `constraint_set3_flag` as follows.

- If `level_idc` is equal to 11 and `constraint_set3_flag` is equal to 1, the indicated level is level 1b.
- Otherwise (`level_idc` is not equal to 11 or `constraint_set3_flag` is not equal to 1), `level_idc` shall be set equal to a value of ten times the level number specified in Table A-1 and `constraint_set3_flag` shall be set equal to 0.

Table A-1 – Level limits

Level number	Max macroblock processing rate MaxMBPS (MB/s)	Max frame size MaxFS (MBs)	Max decoded picture buffer size MaxDPB (1024 bytes for 4:2:0)	Max video bit rate MaxBR (1000 bits/s, 1200 bits/s, cpbBrVclFactor bits/s, or cpbBrNalFactor bits/s)	Max CPB size MaxCPB (1000 bits, 1200 bits, cpbBrVclFactor bits, or cpbBrNalFactor bits)	Vertical MV component range MaxVmvR (luma frame samples)	Min compression ratio MinCR	Max number of motion vectors per two consecutive MBs MaxMvsPer2Mb
1	1 485	99	148.5	64	175	[-64,+63.75]	2	-
1b	1 485	99	148.5	128	350	[-64,+63.75]	2	-
1.1	3 000	396	337.5	192	500	[-128,+127.75]	2	-
1.2	6 000	396	891.0	384	1 000	[-128,+127.75]	2	-
1.3	11 880	396	891.0	768	2 000	[-128,+127.75]	2	-
2	11 880	396	891.0	2 000	2 000	[-128,+127.75]	2	-
2.1	19 800	792	1 782.0	4 000	4 000	[-256,+255.75]	2	-
2.2	20 250	1 620	3 037.5	4 000	4 000	[-256,+255.75]	2	-
3	40 500	1 620	3 037.5	10 000	10 000	[-256,+255.75]	2	32
3.1	108 000	3 600	6 750.0	14 000	14 000	[-512,+511.75]	4	16
3.2	216 000	5 120	7 680.0	20 000	20 000	[-512,+511.75]	4	16
4	245 760	8 192	12 288.0	20 000	25 000	[-512,+511.75]	4	16
4.1	245 760	8 192	12 288.0	50 000	62 500	[-512,+511.75]	2	16
4.2	522 240	8 704	13 056.0	50 000	62 500	[-512,+511.75]	2	16
5	589 824	22 080	41 400.0	135 000	135 000	[-512,+511.75]	2	16
5.1	983 040	36 864	69 120.0	240 000	240 000	[-512,+511.75]	2	16

Levels with non-integer level numbers in Table A-1 are referred to as “intermediate levels”.

NOTE 2 – All levels have the same status, but some applications may choose to use only the integer-numbered levels.

Informative subclause A.3.4 shows the effect of these limits on frame rates for several example picture formats.

A.3.2 Level limits common to the High, High 10, High 4:2:2, and High 4:4:4 profiles

Let the variable fR be derived as follows.

- If picture n is a frame, fR is set equal to $1 \div 172$.
- Otherwise (picture n is a field), fR is set equal to $1 \div (172 * 2)$.

Bitstreams conforming to the High, High 10, High 4:2:2, or High 4:4:4 profiles at a specified level shall obey the following constraints:

- a) The nominal removal time of access unit n (with $n > 0$) from the CPB as specified in subclause C.1.2, satisfies the constraint that $t_{r,n}(n) - t_r(n-1)$ is greater than or equal to $\text{Max}(\text{PicSizeInMbs} \div \text{MaxMBPS}, \text{fR})$, where MaxMBPS is the value specified in Table A-1 that applies to picture n – 1, and PicSizeInMbs is the number of macroblocks in picture n – 1.
- b) The difference between consecutive output times of pictures from the DPB as specified in subclause C.2.2, satisfies the constraint that $\Delta t_{o,dpb}(n) \geq \text{Max}(\text{PicSizeInMbs} \div \text{MaxMBPS}, \text{fR})$, where MaxMBPS is the value specified in Table A-1 for picture n, and PicSizeInMbs is the number of macroblocks of picture n, provided that picture n is a picture that is output and is not the last picture of the bitstream that is output.
- c) $\text{PicWidthInMbs} * \text{FrameHeightInMbs} \leq \text{MaxFS}$, where MaxFS is specified in Table A-1

- d) $\text{PicWidthInMbs} \leq \text{Sqrt}(\text{MaxFS} * 8)$
- e) $\text{FrameHeightInMbs} \leq \text{Sqrt}(\text{MaxFS} * 8)$
- f) $\text{max_dec_frame_buffering} \leq \text{MaxDpbSize}$, where MaxDpbSize is equal to $\text{Min}(1024 * \text{MaxDPB} / (\text{PicWidthInMbs} * \text{FrameHeightInMbs} * 384), 16)$ and MaxDPB is specified in Table A-1.
- g) Vertical motion vector component range does not exceed MaxVmvR in units of luma frame samples, where MaxVmvR is specified in Table A-1.
- h) Horizontal motion vector range does not exceed the range of -2048 to 2047.75, inclusive, in units of luma samples.
- i) Number of motion vectors per two consecutive macroblocks in decoding order (also applying to the total from the last macroblock of a slice and the first macroblock of the next slice in decoding order) does not exceed MaxMvsPer2Mb , where MaxMvsPer2Mb is specified in Table A-1. The number of motion vectors for each macroblock is value of the variable MvCnt after the completion of the intra or inter prediction process for the macroblock.
- j) Number of bits of $\text{macroblock_layer}()$ data for any macroblock is not greater than $128 + \text{RawMbBits}$. Depending on $\text{entropy_coding_mode_flag}$, the bits of $\text{macroblock_layer}()$ data are counted as follows.
 - If $\text{entropy_coding_mode_flag}$ is equal to 0, the number of bits of $\text{macroblock_layer}()$ data is given by the number of bits in the $\text{macroblock_layer}()$ syntax structure for a macroblock.
 - Otherwise ($\text{entropy_coding_mode_flag}$ is equal to 1), the number of bits of $\text{macroblock_layer}()$ data for a macroblock is given by the number of times $\text{read_bits}(1)$ is called in subclauses 9.3.3.2.2 and 9.3.3.2.3 when parsing the $\text{macroblock_layer}()$ associated with the macroblock.

Table A-1 specifies the limits for each level. Entries marked "-" in Table A-1 denote the absence of a corresponding limit.

A level to which the bitstream conforms shall be indicated by the syntax element level_idc as follows.

- If level_idc is equal to 9, the indicated level is level 1b.
- Otherwise (level_idc is not equal to 9), level_idc shall be set equal to a value of ten times the level number specified in Table A-1.

A.3.3 Profile-specific level limits

- a) In bitstreams conforming to the Main, High, High 10, High 4:2:2, or High 4:4:4 profiles, the removal time of access unit 0 shall satisfy the constraint that the number of slices in picture 0 is less than or equal to $(\text{PicSizeInMbs} + \text{MaxMBPS} * (\text{t}_r(0) - \text{t}_{r,n}(0))) \div \text{SliceRate}$, where SliceRate is the value specified in Table A-4 that applies to picture 0.
- b) In bitstreams conforming to the Main, High, High 10, High 4:2:2, or High 4:4:4 profiles, the difference between consecutive removal time of access units n and $n - 1$ (with $n > 0$) shall satisfy the constraint that the number of slices in picture n is less than or equal to $\text{MaxMBPS} * (\text{t}_r(n) - \text{t}_r(n - 1)) \div \text{SliceRate}$, where SliceRate is the value specified in Table A-4 that applies to picture n .
- c) In bitstreams conforming to the Main, High, High 10, High 4:2:2, or High 4:4:4 profiles, sequence parameter sets shall have $\text{direct_8x8_inference_flag}$ equal to 1 for the levels specified in Table A-4.
 NOTE 1 – $\text{direct_8x8_inference_flag}$ is not relevant to the Baseline profile as it does not allow B slice types (specified in subclause A.2.1), and $\text{direct_8x8_inference_flag}$ is equal to 1 for all levels of the Extended profile (specified in subclause A.2.3).
- d) In bitstreams conforming to the Main, High, High 10, High 4:2:2, or High 4:4:4 or Extended profiles, sequence parameter sets shall have $\text{frame_mbs_only_flag}$ equal to 1 for the levels specified in Table A-4 for the Main, High, High 10, High 4:2:2, and High 4:4:4 profiles and in Table A-5 for the Extended profile.
 NOTE 2 – $\text{frame_mbs_only_flag}$ is equal to 1 for all levels of the Baseline profile (specified in subclause A.2.1).
- e) In bitstreams conforming to the Main, High, High 10, High 4:2:2, or High 4:4:4 or Extended profiles, the value of sub_mb_type in B macroblocks shall not be equal to B_Bi_8x4 , B_Bi_4x8 , or B_Bi_4x4 for the levels in which MinLumaBiPredSize is shown as 8x8 in Table A-4 for the Main, High, High 10, High 4:2:2, and High 4:4:4 profiles and in Table A-5 for the Extended profile.
- f) In bitstreams conforming to the Baseline and Extended profiles, $(\text{xInt}_{\text{max}} - \text{xInt}_{\text{min}} + 6) * (\text{yInt}_{\text{max}} - \text{yInt}_{\text{min}} + 6) \leq \text{MaxSubMbRectSize}$ in macroblocks coded with mb_type equal to P_8x8 , P_8x8ref0 or B_8x8 for all

invocations of the process specified in subclause 8.4.2.2.1 used to generate the predicted luma sample array for a single reference picture list (reference picture list 0 or reference picture list 1) for each 8x8 sub-macroblock, where $\text{NumSubMbPart}(\text{sub_mb_type}) > 1$, where MaxSubMbRectSize is specified in Table A-3 for the Baseline profile and in Table A-5 for the Extended profile and

- xInt_{\min} is the minimum value of xInt_L among all luma sample predictions for the sub-macroblock
 - xInt_{\max} is the maximum value of xInt_L among all luma sample predictions for the sub-macroblock
 - yInt_{\min} is the minimum value of yInt_L among all luma sample predictions for the sub-macroblock
 - yInt_{\max} is the maximum value of yInt_L among all luma sample predictions for the sub-macroblock
- g) In bitstreams conforming to the High, High 10, High 4:2:2, or High 4:4:4 profile, for the VCL HRD parameters, $\text{BitRate}[\text{SchedSelIdx}] \leq \text{cpbBrVclFactor} * \text{MaxBR}$ and $\text{CpbSize}[\text{SchedSelIdx}] \leq \text{cpbBrVclFactor} * \text{MaxCPB}$ for at least one value of SchedSelIdx , where cpbBrVclFactor is specified in Table A-2, $\text{BitRate}[\text{SchedSelIdx}]$ is specified by Equation E-37 and $\text{CpbSize}[\text{SchedSelIdx}]$ is specified by Equation E-38 when $\text{vcl_hrd_parameters_present_flag}$ is equal to 1. MaxBR and MaxCPB are specified in Table A-1 in units of cpbBrVclFactor bits/s and cpbBrVclFactor bits, respectively. The bitstream shall satisfy these conditions for at least one value of SchedSelIdx in the range 0 to cpb_cnt_minus1 , inclusive.
- h) In bitstreams conforming to the High, High 10, High 4:2:2, or High 4:4:4 profile, for the NAL HRD parameters, $\text{BitRate}[\text{SchedSelIdx}] \leq \text{cpbBrNalFactor} * \text{MaxBR}$ and $\text{CpbSize}[\text{SchedSelIdx}] \leq \text{cpbBrNalFactor} * \text{MaxCPB}$ for at least one value of SchedSelIdx , where cpbBrNalFactor is specified in Table A-2, $\text{BitRate}[\text{SchedSelIdx}]$ is specified by Equation E-37 and $\text{CpbSize}[\text{SchedSelIdx}]$ is specified by Equation E-38 when $\text{nal_hrd_parameters_present_flag}$ equal to 1. MaxBR and MaxCPB are specified in Table A-1 in units of cpbBrNalFactor bits/s and cpbBrNalFactor bits, respectively. The bitstream shall satisfy these conditions for at least one value of SchedSelIdx in the range 0 to cpb_cnt_minus1 .

Table A-2 – Specification of cpbBrVclFactor and cpbBrNalFactor

Profile	cpbBrVclFactor	cpbBrNalFactor
High	1 250	1 500
High 10	3 000	3 600
High 4:2:2	4 000	4 800
High 4:4:4	4 000	4 800

A.3.3.1 Baseline profile limits

Table A-3 specifies limits for each level that are specific to bitstreams conforming to the Baseline profile. Entries marked "-" in Table A-3 denote the absence of a corresponding limit.

Table A-3 – Baseline profile level limits

A.3.4 Effect of level limits on frame rate (informative)

This subclause does not form an integral part of this Recommendation | International Standard.

Table A-6 – Maximum frame rates (frames per second) for some example frame sizes

Level:					1	1b	1.1	1.2	1.3	2	2.1
Max frame size (macroblocks):					99	99	396	396	396	396	792
Max macroblocks/second:					1 485	1 485	3 000	6 000	11 880	11 880	19 800

The following should be noted.

- This Recommendation | International Standard is a variable-frame-size specification. The specific frame sizes in Table A-6 are illustrative examples only.
- As used in Table A-6, "525" refers to typical use for environments using 525 analogue scan lines (of which approximately 480 lines contain the visible picture region), and "625" refers to environments using 625 analogue scan lines (of which approximately 576 lines contain the visible picture region).
- XGA is also known as (aka) XVGA, 4SVGA aka UXGA, 16XGA aka 4Kx3K, CIF aka 625 SIF, 625 HHR aka 2CIF aka half 625 D-1, aka half 625 ITU-R BT.601, 525 SD aka 525 D-1 aka 525 ITU-R BT.601, 625 SD aka 625 D-1 aka 625 ITU-R BT.601.
- Frame rates given are correct for progressive scan modes. The frame rates are also correct for interlaced video coding for the cases of frame height divisible by 32.

Annex B

Byte stream format

(This annex forms an integral part of this Recommendation | International Standard)

This annex specifies syntax and semantics of a byte stream format specified for use by applications that deliver some or all of the NAL unit stream as an ordered stream of bytes or bits within which the locations of NAL unit boundaries need to be identifiable from patterns in the data, such as ITU-T Rec. H.222.0 | ISO/IEC 13818-1 systems or ITU-T Rec. H.320 systems. For bit-oriented delivery, the bit order for the byte stream format is specified to start with the MSB of the first byte, proceed to the LSB of the first byte, followed by the MSB of the second byte, etc.

The byte stream format consists of a sequence of byte stream NAL unit syntax structures. Each byte stream NAL unit syntax structure contains one start code prefix followed by one `nal_unit(NumBytesInNALunit)` syntax structure. It may (and under some circumstances, it shall) also contain an additional `zero_byte` syntax element. It may also contain one or more additional `trailing_zero_8bits` syntax elements. When it is the first byte stream NAL unit in the bitstream, it may also contain one or more additional `leading_zero_8bits` syntax elements.

B.1 Byte stream NAL unit syntax and semantics

B.1.1 Byte stream NAL unit syntax

byte_stream_nal_unit(NumBytesInNALunit) {	C	Descriptor
while(next_bits(24) != 0x000001 && next_bits(32) != 0x00000001)		
leading_zero_8bits /* equal to 0x00 */		f(8)
if(next_bits(24) != 0x000001)		
zero_byte /* equal to 0x00 */		f(8)
start_code_prefix_one_3bytes /* equal to 0x000001 */		f(24)
nal_unit(NumBytesInNALunit)		
while(more_data_in_byte_stream() && next_bits(24) != 0x000001 && next_bits(32) != 0x00000001)		
trailing_zero_8bits /* equal to 0x00 */		f(8)
}		

B.1.2 Byte stream NAL unit semantics

The order of byte stream NAL units in the byte stream shall follow the decoding order of the NAL units contained in the byte stream NAL units (see subclause 7.4.1.2). The content of each byte stream NAL unit is associated with the same access unit as the NAL unit contained in the byte stream NAL unit (see subclause 7.4.1.2.3).

leading_zero_8bits is a byte equal to 0x00.

NOTE – The `leading_zero_8bits` syntax element can only be present in the first byte stream NAL unit of the bitstream, because (as shown in the syntax diagram of subclause B.1.1) any bytes equal to 0x00 that follow a NAL unit syntax structure and precede the four-byte sequence 0x00000001 (which is to be interpreted as a `zero_byte` followed by a `start_code_prefix_one_3bytes`) will be considered to be `trailing_zero_8bits` syntax elements that are part of the preceding byte stream NAL unit.

zero_byte is a single byte equal to 0x00.

When any of the following conditions are fulfilled, the `zero_byte` syntax element shall be present.

- the `nal_unit_type` within the `nal_unit()` is equal to 7 (sequence parameter set) or 8 (picture parameter set)
- the byte stream NAL unit syntax structure contains the first NAL unit of an access unit in decoding order, as specified by subclause 7.4.1.2.3.

start_code_prefix_one_3bytes is a fixed-value sequence of 3 bytes equal to 0x000001. This syntax element is called a start code prefix.

trailing_zero_8bits is a byte equal to 0x00.

B.2 Byte stream NAL unit decoding process

Input to this process consists of an ordered stream of bytes consisting of a sequence of byte stream NAL unit syntax structures.

Output of this process consists of a sequence of NAL unit syntax structures.

At the beginning of the decoding process, the decoder initialises its current position in the byte stream to the beginning of the byte stream. It then extracts and discards each `leading_zero_8bits` syntax element (if present), moving the current position in the byte stream forward one byte at a time, until the current position in the byte stream is such that the next four bytes in the bitstream form the four-byte sequence `0x00000001`.

The decoder then performs the following step-wise process repeatedly to extract and decode each NAL unit syntax structure in the byte stream until the end of the byte stream has been encountered (as determined by unspecified means) and the last NAL unit in the byte stream has been decoded:

1. When the next four bytes in the bitstream form the four-byte sequence `0x00000001`, the next byte in the byte stream (which is a `zero_byte` syntax element) is extracted and discarded and the current position in the byte stream is set equal to the position of the byte following this discarded byte.
2. The next three-byte sequence in the byte stream (which is a `start_code_prefix_one_3bytes`) is extracted and discarded and the current position in the byte stream is set equal to the position of the byte following this three-byte sequence.
3. `NumBytesInNALunit` is set equal to the number of bytes starting with the byte at the current position in the byte stream up to and including the last byte that precedes the location of any of the following conditions:
 - a. A subsequent byte-aligned three-byte sequence equal to `0x000000`, or
 - b. A subsequent byte-aligned three-byte sequence equal to `0x000001`, or
 - c. The end of the byte stream, as determined by unspecified means.
4. `NumBytesInNALunit` bytes are removed from the bitstream and the current position in the byte stream is advanced by `NumBytesInNALunit` bytes. This sequence of bytes is `nal_unit(NumBytesInNALunit)` and is decoded using the NAL unit decoding process.
5. When the current position in the byte stream is not at the end of the byte stream (as determined by unspecified means) and the next bytes in the byte stream do not start with a three-byte sequence equal to `0x000001` and the next bytes in the byte stream do not start with a four byte sequence equal to `0x00000001`, the decoder extracts and discards each `trailing_zero_8bits` syntax element, moving the current position in the byte stream forward one byte at a time, until the current position in the byte stream is such that the next bytes in the byte stream form the four-byte sequence `0x00000001` or the end of the byte stream has been encountered (as determined by unspecified means).

B.3 Decoder byte-alignment recovery (informative)

This subclause does not form an integral part of this Recommendation | International Standard.

Many applications provide data to a decoder in a manner that is inherently byte aligned, and thus have no need for the bit-oriented byte alignment detection procedure described in this subclause.

A decoder is said to have byte-alignment with a bitstream when the decoder is able to determine whether or not the positions of data in the bitstream are byte-aligned. When a decoder does not have byte alignment with the encoder's byte stream, the decoder may examine the incoming bitstream for the binary pattern '00000000 00000000 00000000 00000001' (31 consecutive bits equal to 0 followed by a bit equal to 1). The bit immediately following this pattern is the first bit of an aligned byte following a start code prefix. Upon detecting this pattern, the decoder will be byte aligned with the encoder and positioned at the start of a NAL unit in the byte stream.

Once byte aligned with the encoder, the decoder can examine the incoming byte stream for subsequent three-byte sequences `0x000001` and `0x000003`.

When the three-byte sequence `0x000001` is detected, this is a start code prefix.

When the three-byte sequence `0x000003` is detected, the third byte (`0x03`) is an `emulation_prevention_three_byte` to be discarded as specified in subclause 7.4.1.

When an error in the bitstream syntax is detected (e.g., a non-zero value of the `forbidden_zero_bit` or one of the three-byte or four-byte sequences that are prohibited in subclause 7.4.1), the decoder may consider the detected condition as an indication that byte alignment may have been lost and may discard all bitstream data until the detection of byte alignment at a later position in the bitstream as described in this subclause.

Recommendation | International Standard. For the purpose of counting bits, only the appropriate bits that are actually present in the bitstream are counted.

NOTE 1 – As an example, synchronization of a non-VCL NAL unit, conveyed by means other than presence in the bitstream, with the NAL units that are present in the bitstream, can be achieved by indicating two points in the bitstream, between which the non-VCL NAL unit would have been present in the bitstream, had the encoder decided to convey it in the bitstream.

When the content of a non-VCL NAL unit is conveyed for the application by some means other than presence within the bitstream, the representation of the content of the non-VCL NAL unit is not required to use the same syntax specified in this annex.

NOTE 2 – When HRD information is contained within the bitstream, it is possible to verify the conformance of a bitstream to the requirements of this subclause based solely on information contained in the bitstream. When the HRD information is not present in the bitstream, as is the case for all "stand-alone" Type I bitstreams, conformance can only be verified when the HRD data is supplied by some other means not specified in this Recommendation | International Standard.

The HRD contains a coded picture buffer (CPB), an instantaneous decoding process, a decoded picture buffer (DPB), and output cropping as shown in Figure C-2.

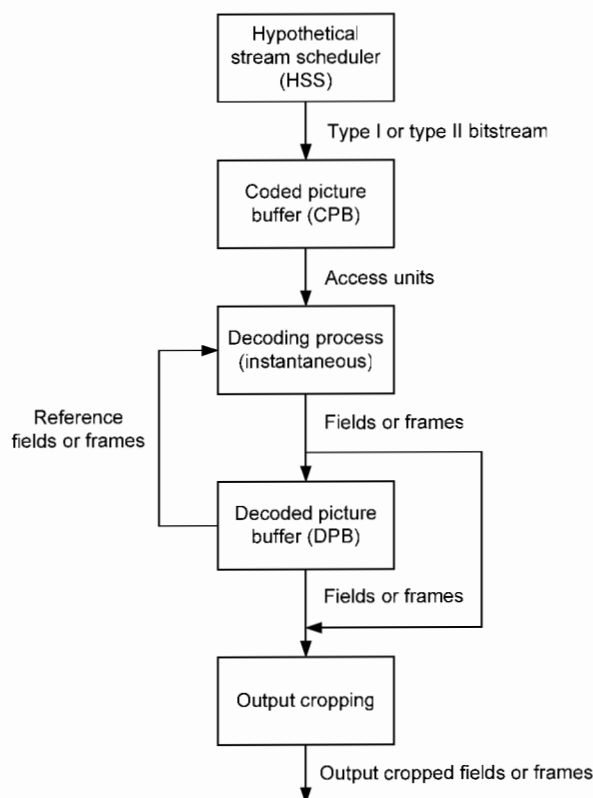

Figure C-2 – HRD buffer model

The CPB size (number of bits) is $CpbSize[SchedSelIdx]$. The DPB size (number of frame buffers) is $Max(1, max_dec_frame_buffering)$.

The HRD operates as follows. Data associated with access units that flow into the CPB according to a specified arrival schedule are delivered by the HSS. The data associated with each access unit are removed and decoded instantaneously by the instantaneous decoding process at CPB removal times. Each decoded picture is placed in the DPB at its CPB removal time unless it is output at its CPB removal time and is a non-reference picture. When a picture is placed in the DPB it is removed from the DPB at the later of the DPB output time or the time that it is marked as "unused for reference".

The operation of the CPB is specified in subclause C.1. The instantaneous decoder operation is specified in clauses 8 and 9. The operation of the DPB is specified in subclause C.2. The output cropping is specified in subclause C.2.2.

HSS and HRD information concerning the number of enumerated delivery schedules and their associated bit rates and buffer sizes is specified in subclauses E.1.1, E.1.2, E.2.1 and E.2.2. The HRD is initialised as specified by the buffering period SEI message as specified in subclauses D.1.1 and D.2.1. The removal timing of access units from the CPB and output timing from the DPB are specified in the picture timing SEI message as specified in subclauses D.1.2 and D.2.2. All timing information relating to a specific access unit shall arrive prior to the CPB removal time of the access unit.

The HRD is used to check conformance of bitstreams and decoders as specified in subclauses C.3 and C.4, respectively.

NOTE 3 – While conformance is guaranteed under the assumption that all frame-rates and clocks used to generate the bitstream match exactly the values signalled in the bitstream, in a real system each of these may vary from the signalled or specified value.

All the arithmetic in this annex is done with real values, so that no rounding errors can propagate. For example, the number of bits in a CPB just prior to or after removal of an access unit is not necessarily an integer.

The variable t_c is derived as follows and is called a clock tick.

$$t_c = \text{num_units_in_tick} \div \text{time_scale} \quad (\text{C-1})$$

The following is specified for expressing the constraints in this Annex.

- Let access unit n be the n -th access unit in decoding order with the first access unit being access unit 0.
- Let picture n be the primary coded picture or the decoded primary picture of access unit n .

C.1 Operation of coded picture buffer (CPB)

The specifications in this subclause apply independently to each set of CPB parameters that is present and to both the Type I and Type II conformance points shown in Figure C-1.

C.1.1 Timing of bitstream arrival

The HRD may be initialised at any one of the buffering period SEI messages. Prior to initialisation, the CPB is empty.

NOTE – After initialisation, the HRD is not initialised again by subsequent buffering period SEI messages.

Each access unit is referred to as access unit n , where the number n identifies the particular access unit. The access unit that is associated with the buffering period SEI message that initializes the CPB is referred to as access unit 0. The value of n is incremented by 1 for each subsequent access unit in decoding order.

The time at which the first bit of access unit n begins to enter the CPB is referred to as the initial arrival time $t_{ai}(n)$.

The initial arrival time of access units is derived as follows.

- If the access unit is access unit 0, $t_{ai}(0) = 0$,
- Otherwise (the access unit is access unit n with $n > 0$), the following applies.
 - If $\text{cbr_flag}[\text{SchedSelIdx}]$ is equal to 1, the initial arrival time for access unit n , is equal to the final arrival time (which is derived below) of access unit $n - 1$, i.e.

$$t_{ai}(n) = t_{af}(n - 1) \quad (\text{C-2})$$

- Otherwise ($\text{cbr_flag}[\text{SchedSelIdx}]$ is equal to 0), the initial arrival time for access unit n is derived by

$$t_{ai}(n) = \text{Max}(t_{af}(n - 1), t_{ai,earliest}(n)) \quad (\text{C-3})$$

where $t_{ai,earliest}(n)$ is derived as follows

- If access unit n is not the first access unit of a subsequent buffering period, $t_{ai,earliest}(n)$ is derived as

$$t_{ai,earliest}(n) = t_{r,n}(n) - (\text{initial_cpb_removal_delay}[\text{SchedSelIdx}] + \text{initial_cpb_removal_delay_offset}[\text{SchedSelIdx}]) \div 90000 \quad (\text{C-4})$$

with $t_{r,n}(n)$ being the nominal removal time of access unit n from the CPB as specified in subclause C.1.2 and $\text{initial_cpb_removal_delay}[\text{SchedSelIdx}]$ and $\text{initial_cpb_removal_delay_offset}[\text{SchedSelIdx}]$ being specified in the previous buffering period SEI message.

- Otherwise (access unit n is the first access unit of a subsequent buffering period), $t_{ai,earliest}(n)$ is derived as

$$t_{ai,earliest}(n) = t_{r,n}(n) - (\text{initial_cpb_removal_delay}[\text{SchedSelIdx}] \div 90000) \quad (\text{C-5})$$

with $\text{initial_cpb_removal_delay}[\text{SchedSelIdx}]$ being specified in the buffering period SEI message associated with access unit n .

The final arrival time for access unit n is derived by

$$t_{af}(n) = t_{ai}(n) + b(n) \div \text{BitRate}[\text{SchedSelIdx}] \quad (\text{C-6})$$

where $b(n)$ is the size in bits of access unit n , counting the bits of the VCL NAL units and the filler data NAL units for the Type I conformance point or all bits of the Type II bitstream for the Type II conformance point, where the Type I and Type II conformance points are as shown in Figure C-1.

The values of SchedSelIdx , $\text{BitRate}[\text{SchedSelIdx}]$, and $\text{CpbSize}[\text{SchedSelIdx}]$ are constrained as follows.

- If access unit n and access unit $n - 1$ are part of different coded video sequences and the content of the active sequence parameter sets of the two coded video sequences differ, the HSS selects a value SchedSelIdx1 of SchedSelIdx from among the values of SchedSelIdx provided for the coded video sequence containing access unit n that results in a $\text{BitRate}[\text{SchedSelIdx1}]$ or $\text{CpbSize}[\text{SchedSelIdx1}]$ for the second of the two coded video sequences (which contains access unit n). The value of $\text{BitRate}[\text{SchedSelIdx1}]$ or $\text{CpbSize}[\text{SchedSelIdx1}]$ may differ from the value of $\text{BitRate}[\text{SchedSelIdx0}]$ or $\text{CpbSize}[\text{SchedSelIdx0}]$ for the value SchedSelIdx0 of SchedSelIdx that was in use for the coded video sequence containing access unit $n - 1$.
- Otherwise, the HSS continues to operate with the previous values of SchedSelIdx , $\text{BitRate}[\text{SchedSelIdx}]$ and $\text{CpbSize}[\text{SchedSelIdx}]$.

When the HSS selects values of $\text{BitRate}[\text{SchedSelIdx}]$ or $\text{CpbSize}[\text{SchedSelIdx}]$ that differ from those of the previous access unit, the following applies.

- the variable $\text{BitRate}[\text{SchedSelIdx}]$ comes into effect at time $t_{ai}(n)$
- the variable $\text{CpbSize}[\text{SchedSelIdx}]$ comes into effect as follows.
 - If the new value of $\text{CpbSize}[\text{SchedSelIdx}]$ exceeds the old CPB size, it comes into effect at time $t_{ai}(n)$,
 - Otherwise, the new value of $\text{CpbSize}[\text{SchedSelIdx}]$ comes into effect at the time $t_r(n)$.

C.1.2 Timing of coded picture removal

For access unit 0, the nominal removal time of the access unit from the CPB is specified by

$$t_{r,n}(0) = \text{initial_cpb_removal_delay}[\text{SchedSelIdx}] \div 90000 \quad (\text{C-7})$$

For the first access unit of a buffering period that does not initialise the HRD, the nominal removal time of the access unit from the CPB is specified by

$$t_{r,n}(n) = t_{r,n}(n_b) + t_c * \text{cpb_removal_delay}(n) \quad (\text{C-8})$$

where $t_{r,n}(n_b)$ is the nominal removal time of the first access unit of the previous buffering period and $\text{cpb_removal_delay}(n)$ is the value of cpb_removal_delay specified in the picture timing SEI message associated with access unit n .

When an access unit n is the first access unit of a buffering period, n_b is set equal to n at the removal time of access unit n .

The nominal removal time $t_{r,n}(n)$ of an access unit n that is not the first access unit of a buffering period is given by

$$t_{r,n}(n) = t_{r,n}(n_b) + t_c * \text{cpb_removal_delay}(n) \quad (\text{C-9})$$

where $t_{r,n}(n_b)$ is the nominal removal time of the first access unit of the current buffering period and $\text{cpb_removal_delay}(n)$ is the value of cpb_removal_delay specified in the picture timing SEI message associated with access unit n .

The removal time of access unit n is specified as follows.

- If `low_delay_hrd_flag` is equal to 0 or $t_{r,n}(n) \geq t_{af}(n)$, the removal time of access unit n is specified by

$$t_r(n) = t_{r,n}(n) \quad (C-10)$$

- Otherwise (`low_delay_hrd_flag` is equal to 1 and $t_{r,n}(n) < t_{af}(n)$), the removal time of access unit n is specified by

$$t_r(n) = t_{r,n}(n) + t_c * \text{Ceil}((t_{af}(n) - t_{r,n}(n)) \div t_c) \quad (C-11)$$

NOTE – The latter case indicates that the size of access unit n , $b(n)$, is so large that it prevents removal at the nominal removal time.

C.2 Operation of the decoded picture buffer (DPB)

The decoded picture buffer contains frame buffers. Each of the frame buffers may contain a decoded frame, a decoded complementary field pair or a single (non-paired) decoded field that are marked as "used for reference" (reference pictures) or are held for future output (reordered or delayed pictures). Prior to initialisation, the DPB is empty (the DPB fullness is set to zero). The following steps of the subclauses of this subclause all happen instantaneously at $t_r(n)$ and in the sequence listed.

C.2.1 Decoding of gaps in `frame_num` and storage of "non-existing" frames

If applicable, gaps in `frame_num` are detected by the decoding process and the generated frames are marked and inserted into the DPB as specified below.

Gaps in `frame_num` are detected by the decoding process and the generated frames are marked as specified in subclause 8.2.5.2.

After the marking of each generated frame, each picture m marked by the "sliding window" process as "unused for reference" is removed from the DPB when it is also marked as "non-existing" or its DPB output time is less than or equal to the CPB removal time of the current picture n ; i.e., $t_{o,dpb}(m) \leq t_r(n)$. When a frame or the last field in a frame buffer is removed from the DPB, the DPB fullness is decremented by one. The "non-existing" generated frame is inserted into the DPB and the DPB fullness is incremented by one.

C.2.2 Picture decoding and output

Picture n is decoded and its DPB output time $t_{o,dpb}(n)$ is derived by

$$t_{o,dpb}(n) = t_r(n) + t_c * \text{dpb_output_delay}(n) \quad (C-12)$$

The output of the current picture is specified as follows.

- If $t_{o,dpb}(n) = t_r(n)$, the current picture is output.

NOTE – When the current picture is a reference picture it will be stored in the DPB.

- Otherwise ($t_{o,dpb}(n) > t_r(n)$), the current picture is output later and will be stored in the DPB (as specified in subclause C.2.4) and is output at time $t_{o,dpb}(n)$ unless indicated not to be output by the decoding or inference of `no_output_of_prior_pics_flag` equal to 1 at a time that precedes $t_{o,dpb}(n)$.

The output picture shall be cropped, using the cropping rectangle specified in the sequence parameter set for the sequence.

When picture n is a picture that is output and is not the last picture of the bitstream that is output, the value of $\Delta t_{o,dpb}(n)$ is defined as:

$$\Delta t_{o,dpb}(n) = t_{o,dpb}(n_n) - t_{o,dpb}(n) \quad (C-13)$$

where n_n indicates the picture that follows after picture n in output order.

The decoded picture is temporarily stored (not in the DPB).

C.2.3 Removal of pictures from the DPB before possible insertion of the current picture

The removal of pictures from the DPB before possible insertion of the current picture proceeds as follows.

- If the decoded picture is an IDR picture the following applies.

- All reference pictures in the DPB are marked as "unused for reference" as specified in subclause 8.2.5.1.
- When the IDR picture is not the first IDR picture decoded and the value of `PicWidthInMbs` or `FrameHeightInMbs` or `max_dec_frame_buffering` derived from the active sequence parameter set is different from the value of `PicWidthInMbs` or `FrameHeightInMbs` or `max_dec_frame_buffering` derived from the sequence parameter set that was active for the preceding sequence, respectively, `no_output_of_prior_pics_flag` is inferred to be equal to 1 by the HRD, regardless of the actual value of `no_output_of_prior_pics_flag`.
NOTE – Decoder implementations should try to handle frame or DPB size changes more gracefully than the HRD in regard to changes in `PicWidthInMbs` or `FrameHeightInMbs`.
- When `no_output_of_prior_pics_flag` is equal to 1 or is inferred to be equal to 1, all frame buffers in the DPB are emptied without output of the pictures they contain, and DPB fullness is set to 0.
- Otherwise (the decoded picture is not an IDR picture), the following applies.
 - If the slice header of the current picture includes `memory_management_control_operation` equal to 5, all reference pictures in the DPB are marked as "unused for reference".
 - Otherwise (the slice header of the current picture does not include `memory_management_control_operation` equal to 5), the decoded reference picture marking process specified in subclause 8.2.5 is invoked.

All pictures m in the DPB, for which all of the following conditions are true, are removed from the DPB.

- picture m is marked as "unused for reference" or picture m is a non-reference picture. When a picture is a reference frame, it is considered to be marked as "unused for reference" only when both of its fields have been marked as "unused for reference".
- picture m is marked as "non-existing" or its DPB output time is less than or equal to the CPB removal time of the current picture n ; i.e., $t_{o,dpb}(m) \leq t_r(n)$

When a frame or the last field in a frame buffer is removed from the DPB, the DPB fullness is decremented by one.

C.2.4 Current decoded picture marking and storage

C.2.4.1 Marking and storage of a reference decoded picture into the DPB

When the current picture is a reference picture it is stored in the DPB as follows.

- If the current decoded picture is a second field (in decoding order) of a complementary reference field pair, and the first field of the pair is still in the DPB, the current decoded picture is stored in the same frame buffer as the first field of the pair.
- Otherwise, the current decoded picture is stored in an empty frame buffer, and the DPB fullness is incremented by one.

C.2.4.2 Storage of a non-reference picture into the DPB

When the current picture is a non-reference picture and current picture n has $t_{o,dpb}(n) > t_r(n)$, it is stored in the DPB as follows.

- If the current decoded picture is a second field (in decoding order) of a complementary non-reference field pair, and the first field of the pair is still in the DPB, the current decoded picture is stored in the same frame buffer as the first field of the pair.
- Otherwise, the current decoded picture is stored in an empty frame buffer, and the DPB fullness is incremented by one.

C.3 Bitstream conformance

A bitstream of coded data conforming to this Recommendation | International Standard fulfils the following requirements.

The bitstream is constructed according to the syntax, semantics, and constraints specified in this Recommendation | International Standard outside of this Annex.

The bitstream is tested by the HRD as specified below:

For Type I bitstreams, the number of tests carried out is equal to `cpb_cnt_minus1 + 1` where `cpb_cnt_minus1` is either the syntax element of `hrd_parameters()` following the `vcl_hrd_parameters_present_flag` or is determined by the application by other means not specified in this Recommendation | International Standard. One test is carried out for

each bit rate and CPB size combination specified by `hrd_parameters()` following the `vcl_hrd_parameters_present_flag`. Each of these tests is conducted at the Type I conformance point shown in Figure C-1.

For Type II bitstreams there are two sets of tests. The number of tests of the first set is equal to `cpb_cnt_minus1 + 1` where `cpb_cnt_minus1` is either the syntax element of `hrd_parameters()` following the `vcl_hrd_parameters_present_flag` or is determined by the application by other means not specified in this Recommendation | International Standard. One test is carried out for each bit rate and CPB size combination. Each of these tests is conducted at the Type I conformance point shown in Figure C-1. For these tests, only VCL and filler data NAL units are counted for the input bit rate and CPB storage.

The number of tests of the second set, for Type II bitstreams, is equal to `cpb_cnt_minus1 + 1` where `cpb_cnt_minus1` is either the syntax element of `hrd_parameters()` following the `nal_hrd_parameters_present_flag` or is determined by the application by other means not specified in this Recommendation | International Standard. One test is carried out for each bit rate and CPB size combination specified by `hrd_parameters()` following the `nal_hrd_parameters_present_flag`. Each of these tests is conducted at the Type II conformance point shown in Figure C-1. For these tests, all NAL units (of a Type II NAL unit stream) or all bytes (of a byte stream) are counted for the input bit rate and CPB storage.

NOTE 1 – NAL HRD parameters established by a value of `SchedSelIdx` for the Type II conformance point shown in Figure C-1 are sufficient to also establish VCL HRD conformance for the Type I conformance point shown in Figure C-1 for the same values of `initial_cpb_removal_delay[SchedSelIdx]`, `BitRate[SchedSelIdx]`, and `CpbSize[SchedSelIdx]` for the VBR case (`cbr_flag[SchedSelIdx]` equal to 0). This is because the data flow into the Type I conformance point is a subset of the data flow into the Type II conformance point and because, for the VBR case, the CPB is allowed to become empty and stay empty until the time a next picture is scheduled to begin to arrive. For example, when NAL HRD parameters are provided for the Type II conformance point that not only fall within the bounds set for NAL HRD parameters for profile conformance in item j of subclause A.3.1 or item i of subclause A.3.3 (depending on the profile in use) but also fall within the bounds set for VCL HRD parameters for profile conformance in item i of subclause A.3.1 or item h of subclause A.3.3 (depending on the profile in use), conformance of the VCL HRD for the Type I conformance point is also assured to fall within the bounds of item i of subclause A.3.1.

For conforming bitstreams, all of the following conditions shall be fulfilled for each of the tests.

- For each access unit n , with $n > 0$, associated with a buffering period SEI message, with $\Delta t_{g,90}(n)$ specified by

$$\Delta t_{g,90}(n) = 90000 * (t_{r,n}(n) - t_{af}(n-1)) \quad (C-14)$$

The value of `initial_cpb_removal_delay[SchedSelIdx]` shall be constrained as follows.

- If `cbr_flag[SchedSelIdx]` is equal to 0,

$$\text{initial_cpb_removal_delay[SchedSelIdx]} \leq \text{Ceil}(\Delta t_{g,90}(n)) \quad (C-15)$$

- Otherwise (`cbr_flag[SchedSelIdx]` is equal to 1),

$$\text{Floor}(\Delta t_{g,90}(n)) \leq \text{initial_cpb_removal_delay[SchedSelIdx]} \leq \text{Ceil}(\Delta t_{g,90}(n)) \quad (C-16)$$

NOTE 2 – The exact number of bits in the CPB at the removal time of each picture may depend on which buffering period SEI message is selected to initialize the HRD. Encoders must take this into account to ensure that all specified constraints must be obeyed regardless of which buffering period SEI message is selected to initialize the HRD, as the HRD may be initialised at any one of the buffering period SEI messages.

- A CPB overflow is specified as the condition in which the total number of bits in the CPB is larger than the CPB size. The CPB shall never overflow.
- A CPB underflow is specified as the condition in which $t_{r,n}(n)$ is less than $t_{af}(n)$. When `low_delay_hrd_flag` is equal to 0, the CPB shall never underflow.
- The nominal removal times of pictures from the CPB (starting from the second picture in decoding order), shall satisfy the constraints on $t_{r,n}(n)$ and $t_r(n)$ expressed in subclauses A.3.1 through A.3.3 for the profile and level specified in the bitstream.
- Immediately after any decoded picture is added to the DPB, the fullness of the DPB shall be less than or equal to the DPB size as constrained by Annexes A, D, and E for the profile and level specified in the bitstream.
- All reference pictures shall be present in the DPB when needed for prediction. Each picture shall be present in the DPB at its DPB output time unless it is not stored in the DPB at all, or is removed from the DPB before its output time by one of the processes specified in subclause C.2.

- The value of $\Delta_{to,dpb}(n)$ as given by Equation C-13, which is the difference between the output time of a picture and that of the picture immediately following it in output order, shall satisfy the constraint expressed in subclause A.3.1 for the profile and level specified in the bitstream.

C.4 Decoder conformance

A decoder conforming to this Recommendation | International Standard fulfils the following requirements.

A decoder claiming conformance to a specific profile and level shall be able to decode successfully all conforming bitstreams specified for decoder conformance in subclause C.3, provided that all sequence parameter sets and picture parameters sets referred to in the VCL NAL units, and appropriate buffering period and picture timing SEI messages are conveyed to the decoder, in a timely manner, either in the bitstream (by non-VCL NAL units), or by external means not specified by this Recommendation | International Standard.

There are two types of conformance that can be claimed by a decoder: output timing conformance and output order conformance.

To check conformance of a decoder, test bitstreams conforming to the claimed profile and level, as specified by subclause C.3 are delivered by a hypothetical stream scheduler (HSS) both to the HRD and to the decoder under test (DUT). All pictures output by the HRD shall also be output by the DUT and, for each picture output by the HRD, the values of all samples that are output by the DUT for the corresponding picture shall be equal to the values of the samples output by the HRD.

For output timing decoder conformance, the HSS operates as described above, with delivery schedules selected only from the subset of values of SchedSelIdx for which the bit rate and CPB size are restricted as specified in Annex A for the specified profile and level, or with "interpolated" delivery schedules as specified below for which the bit rate and CPB size are restricted as specified in Annex A. The same delivery schedule is used for both the HRD and DUT.

When the HRD parameters and the buffering period SEI messages are present with `cpb_cnt_minus1` greater than 0, the decoder shall be capable of decoding the bitstream as delivered from the HSS operating using an "interpolated" delivery schedule specified as having peak bit rate r , CPB size $c(r)$, and initial CPB removal delay $(f(r) \div r)$ as follows

$$\alpha = (r - \text{BitRate}[\text{SchedSelIdx} - 1]) \div (\text{BitRate}[\text{SchedSelIdx}] - \text{BitRate}[\text{SchedSelIdx} - 1]), \quad (\text{C-17})$$

$$c(r) = \alpha * \text{CpbSize}[\text{SchedSelIdx}] + (1 - \alpha) * \text{CpbSize}[\text{SchedSelIdx} - 1], \quad (\text{C-18})$$

$$f(r) = \alpha * \text{initial_cpb_removal_delay}[\text{SchedSelIdx}] * \text{BitRate}[\text{SchedSelIdx}] + (1 - \alpha) * \text{initial_cpb_removal_delay}[\text{SchedSelIdx} - 1] * \text{BitRate}[\text{SchedSelIdx} - 1] \quad (\text{C-19})$$

for any $\text{SchedSelIdx} > 0$ and r such that $\text{BitRate}[\text{SchedSelIdx} - 1] \leq r \leq \text{BitRate}[\text{SchedSelIdx}]$ such that r and $c(r)$ are within the limits as specified in Annex A for the maximum bit rate and buffer size for the specified profile and level.

NOTE 1 – `initial_cpb_removal_delay[SchedSelIdx]` can be different from one buffering period to another and have to be re-calculated.

For output timing decoder conformance, an HRD as described above is used and the timing (relative to the delivery time of the first bit) of picture output is the same for both HRD and the DUT up to a fixed delay.

For output order decoder conformance, the HSS delivers the bitstream to the DUT "by demand" from the DUT, meaning that the HSS delivers bits (in decoding order) only when the DUT requires more bits to proceed with its processing.

NOTE 2 – This means that for this test, the coded picture buffer of the DUT could be as small as the size of the largest access unit.

A modified HRD as described below is used, and the HSS delivers the bitstream to the HRD by one of the schedules specified in the bitstream such that the bit rate and CPB size are restricted as specified in Annex A. The order of pictures output shall be the same for both HRD and the DUT.

For output order decoder conformance, the HRD CPB size is equal to `CpbSize[SchedSelIdx]` for the selected schedule and the DPB size is equal to `MaxDpbSize`. Removal time from the CPB for the HRD is equal to final bit arrival time and decoding is immediate. The operation of the DPB of this HRD is described below.

C.4.1 Operation of the output order DPB

The decoded picture buffer contains frame buffers. Each of the frame buffers may contain a decoded frame, a decoded complementary field pair or a single (non-paired) decoded field that is marked as "used for reference" or is held for future output (reordered pictures). At HRD initialization, the DPB fullness, measured in frames, is set to 0. The following steps all happen instantaneously when an access unit is removed from the CPB, and in the order listed.

C.4.2 Decoding of gaps in frame_num and storage of "non-existing" pictures

When applicable, gaps in frame_num are detected by the decoding process and the necessary number of "non-existing" frames are inferred in the order specified by the generation of values of UnusedShortTermFrameNum in Equation 7-21 and are marked as specified in subclause 8.2.5.2. Frame buffers containing a frame or a complementary field pair or a non-paired field which are marked as "not needed for output" and "unused for reference" are emptied (without output), and the DPB fullness is decremented by the number of frame buffers emptied. Each "non-existing" frame is stored in the DPB as follows.

- When there is no empty frame buffer (i.e., DPB fullness is equal to DPB size), the "bumping" process specified in subclause C.4.5.3 is invoked repeatedly until there is an empty frame buffer in which to store the "non-existing" frame.
- The "non-existing" frame is stored in an empty frame buffer and is marked as "not needed for output", and the DPB fullness is incremented by one.

C.4.3 Picture decoding

Primary coded picture *n* is decoded and is temporarily stored (not in the DPB).

C.4.4 Removal of pictures from the DPB before possible insertion of the current picture

The removal of pictures from the DPB before possible insertion of the current picture proceeds as follows.

- If the decoded picture is an IDR picture the following applies.
 - All reference pictures in the DPB are marked as "unused for reference" as specified in subclause 8.2.5.
 - When the IDR picture is not the first IDR picture decoded and the value of PicWidthInMbs or FrameHeightInMbs or max_dec_frame_buffering derived from the active sequence parameter set is different from the value of PicWidthInMbs or FrameHeightInMbs or max_dec_frame_buffering derived from the sequence parameter set that was active for the preceding sequence, respectively, no_output_of_prior_pics_flag is inferred to be equal to 1 by the HRD, regardless of the actual value of no_output_of_prior_pics_flag.
NOTE – Decoder implementations should try to handle changes in the value of PicWidthInMbs or FrameHeightInMbs or max_dec_frame_buffering more gracefully than the HRD.
 - When no_output_of_prior_pics_flag is equal to 1 or is inferred to be equal to 1, all frame buffers in the DPB are emptied without output of the pictures they contain, and DPB fullness is set to 0.
- Otherwise (the decoded picture is not an IDR picture), the decoded reference picture marking process is invoked as specified in subclause 8.2.5. Frame buffers containing a frame or a complementary field pair or a non-paired field which are marked as "not needed for output" and "unused for reference" are emptied (without output), and the DPB fullness is decremented by the number of frame buffers emptied.

When the current picture has a memory_management_control_operation equal to 5 or is an IDR picture for which no_output_of_prior_pics_flag is not equal to 1 and is not inferred to be equal to 1, the following two steps are performed.

1. Frame buffers containing a frame or a complementary field pair or a non-paired field which are marked as "not needed for output" and "unused for reference" are emptied (without output), and the DPB fullness is decremented by the number of frame buffers emptied.
2. All non-empty frame buffers in the DPB are emptied by repeatedly invoking the "bumping" process specified in subclause C.4.5.3, and the DPB fullness is set to 0.

C.4.5 Current decoded picture marking and storage

C.4.5.1 Storage and marking of a reference decoded picture into the DPB

When the current picture is a reference picture, it is stored in the DPB as follows.

- If the current decoded picture is the second field (in decoding order) of a complementary reference field pair, and the first field of the pair is still in the DPB, the current picture is stored in the same frame buffer as the first field of the pair and is marked as "needed for output".

- Otherwise, the following operations are performed:
 - When there is no empty frame buffer (i.e., DPB fullness is equal to DPB size), the "bumping" process specified in subclause C.4.5.3 is invoked repeatedly until there is an empty frame buffer in which to store the current decoded picture.
 - The current decoded picture is stored in an empty frame buffer and is marked as "needed for output", and the DPB fullness is incremented by one.

C.4.5.2 Storage and marking of a non-reference decoded picture into the DPB

When the current picture is a non-reference picture, the following operations are performed.

- If the current decoded picture is the second field (in decoding order) of a complementary non-reference field pair and the first field of the pair is still in the DPB, the current picture is stored in the same frame buffer as the first field of the pair and is marked as "needed for output".
- Otherwise, the following operations are performed repeatedly until the current decoded picture has been cropped and output or has been stored in the DPB:
 - If there is no empty frame buffer (i.e., DPB fullness is equal to DPB size), the following applies.
 - If the current picture does not have a lower value of `PicOrderCnt()` than all pictures in the DPB that are marked as "needed for output", the "bumping" process described in subclause C.4.5.3 is performed.
 - Otherwise (the current picture has a lower value of `PicOrderCnt()` than all pictures in the DPB that are marked as "needed for output"), the current picture is cropped, using the cropping rectangle specified in the sequence parameter set for the sequence and the cropped picture is output.
 - Otherwise (there is an empty frame buffer, i.e., DPB fullness is less than DPB size) the current decoded picture is stored in an empty frame buffer and is marked as "needed for output", and the DPB fullness is incremented by one.

C.4.5.3 "Bumping" process

The "bumping" process is invoked in the following cases.

- There is no empty frame buffer (i.e., DPB fullness is equal to DPB size) and an empty frame buffer is needed for storage of an inferred "non-existing" frame, as specified in subclause C.4.2.
- The current picture is an IDR picture and `no_output_of_prior_pics_flag` is not equal to 1 and is not inferred to be equal to 1, as specified in subclause C.4.4.
- The current picture has `memory_management_control_operation` equal to 5, as specified in subclause C.4.4.
- There is no empty frame buffer (i.e., DPB fullness is equal to DPB size) and an empty frame buffer is needed for storage of a decoded (non-IDR) reference picture, as specified in subclause C.4.5.1.
- There is no empty frame buffer (i.e., DPB fullness is equal to DPB size) and the current picture is a non-reference picture that is not the second field of a complementary non-reference field pair and there are pictures in the DPB that are marked as "needed for output" that precede the current non-reference picture in output order, as specified in subclause C.4.5.2, so an empty buffer is needed for storage of the current picture.

The "bumping" process consists of the following:

- The picture or complementary reference field pair that is first for output is selected as follows.
 - The frame buffer is selected that contains the picture having the smallest value of `PicOrderCnt()` of all pictures in the DPB marked as "needed for output".
 - If this frame buffer contains a complementary non-reference field pair with both fields marked as "needed for output" and both fields have the same `PicOrderCnt()`, the first of these two fields in decoding order is considered first for output.
 - Otherwise, if this frame buffer contains a complementary reference field pair with both fields marked as "needed for output" and both fields have the same `PicOrderCnt()`, the entire complementary reference field pair is considered first for output.
 - Otherwise, the picture in this frame buffer that has the smallest value of `PicOrderCnt()` is considered first for output.
- If a single picture is considered first for output, this picture is cropped, using the cropping rectangle specified in the sequence parameter set for the sequence, the cropped picture is output, and the picture is marked as "not needed for output".

- Otherwise (a complementary reference field pair is considered first for output), the two fields of the complementary reference field pair are both cropped, using the cropping rectangle specified in the sequence parameter set for the sequence, the two fields of the complementary reference field pair are output together, and both fields of the complementary reference field pair are marked as "not needed for output".
- The frame buffer that included the picture or complementary reference field pair that was cropped and output is checked, and when any of the following conditions is satisfied, the frame buffer is emptied and the DPB fullness is decremented by 1.
 - The frame buffer contains a non-reference non-paired field.
 - The frame buffer contains a non-reference frame.
 - The frame buffer contains a complementary non-reference field pair with both fields marked as "not needed for output".
 - The frame buffer contains a non-paired reference field marked as "unused for reference".
 - The frame buffer contains a reference frame with both fields marked as "unused for reference".
 - The frame buffer contains a complementary reference field pair with both fields marked as "unused for reference" and "not needed for output".

Annex D

Supplemental enhancement information

(This annex forms an integral part of this Recommendation | International Standard)

This annex specifies syntax and semantics for SEI message payloads.

SEI messages assist in processes related to decoding, display or other purposes. However, SEI messages are not required for constructing the luma or chroma samples by the decoding process. Conforming decoders are not required to process this information for output order conformance to this Recommendation | International Standard (see Annex C for the specification of conformance). Some SEI message information is required to check bitstream conformance and for output timing decoder conformance.

In Annex D, specification for presence of SEI messages are also satisfied when those messages (or some subset of them) are conveyed to decoders (or to the HRD) by other means not specified by this Recommendation | International Standard. When present in the bitstream, SEI messages shall obey the syntax and semantics specified in subclauses 7.3.2.3 and 7.4.2.3 and this annex. When the content of an SEI message is conveyed for the application by some means other than presence within the bitstream, the representation of the content of the SEI message is not required to use the same syntax specified in this annex. For the purpose of counting bits, only the appropriate bits that are actually present in the bitstream are counted.

reserved_sei_message(payloadSize) {	C	Descriptor
for(i = 0; i < payloadSize; i++)		
reserved_sei_message_payload_byte	5	b(8)
}		

D.2 SEI payload semantics

D.2.1 Buffering period SEI message semantics

When NalHrdBpPresentFlag or VclHrdBpPresentFlag are equal to 1, a buffering period SEI message can be associated with any access unit in the bitstream, and a buffering period SEI message shall be associated with each IDR access unit and with each access unit associated with a recovery point SEI message.

NOTE – For some applications, the frequent presence of a buffering period SEI message may be desirable.

A buffering period is specified as the set of access units between two instances of the buffering period SEI message in decoding order.

seq_parameter_set_id specifies the sequence parameter set that contains the sequence HRD attributes. The value of seq_parameter_set_id shall be equal to the value of seq_parameter_set_id in the picture parameter set referenced by the primary coded picture associated with the buffering period SEI message. The value of seq_parameter_set_id shall be in the range of 0 to 31, inclusive.

initial_cpb_removal_delay[SchedSelIdx] specifies the delay for the SchedSelIdx-th CPB between the time of arrival in the CPB of the first bit of the coded data associated with the access unit associated with the buffering period SEI message and the time of removal from the CPB of the coded data associated with the same access unit, for the first buffering period after HRD initialisation. The syntax element has a length in bits given by initial_cpb_removal_delay_length_minus1 + 1. It is in units of a 90 kHz clock. initial_cpb_removal_delay[SchedSelIdx] shall not be equal to 0 and shall not exceed $90000 * (CpbSize[SchedSelIdx] \div BitRate[SchedSelIdx])$, the time-equivalent of the CPB size in 90 kHz clock units.

initial_cpb_removal_delay_offset[SchedSelIdx] is used for the SchedSelIdx-th CPB in combination with the cpb_removal_delay to specify the initial delivery time of coded access units to the CPB. initial_cpb_removal_delay_offset[SchedSelIdx] is in units of a 90 kHz clock. The initial_cpb_removal_delay_offset[SchedSelIdx] syntax element is a fixed length code whose length in bits is given by initial_cpb_removal_delay_length_minus1 + 1. This syntax element is not used by decoders and is needed only for the delivery scheduler (HSS) specified in Annex C.

Over the entire coded video sequence, the sum of initial_cpb_removal_delay[SchedSelIdx] and initial_cpb_removal_delay_offset[SchedSelIdx] shall be constant for each value of SchedSelIdx.

D.2.2 Picture timing SEI message semantics

The presence of picture timing SEI message in the bitstream is specified as follows.

- If CpbDpbDelaysPresentFlag is equal to 1 or pic_struct_present_flag is equal to 1, one picture timing SEI message shall be present in every access unit of the coded video sequence.
- Otherwise (CpbDpbDelaysPresentFlag is equal to 0 and pic_struct_present_flag is equal to 0), no picture timing SEI messages shall be present in any access unit of the coded video sequence.

cpb_removal_delay specifies how many clock ticks (see subclause E.2.1) to wait after removal from the CPB of the access unit associated with the most recent buffering period SEI message before removing from the buffer the access unit data associated with the picture timing SEI message. This value is also used to calculate an earliest possible time of arrival of access unit data into the CPB for the HSS, as specified in Annex C. The syntax element is a fixed length code whose length in bits is given by $\text{cpb_removal_delay_length_minus1} + 1$. The **cpb_removal_delay** is the remainder of a $2^{(\text{cpb_removal_delay_length_minus1} + 1)}$ counter.

The value of **cpb_removal_delay** for the first picture in the bitstream shall be equal to 0.

dpb_output_delay is used to compute the DPB output time of the picture. It specifies how many clock ticks to wait after removal of an access unit from the CPB before the decoded picture can be output from the DPB (see subclause C.2).

NOTE 1 – A picture is not removed from the DPB at its output time when it is still marked as "used for short-term reference" or "used for long-term reference".

NOTE 2 – Only one **dpb_output_delay** is specified for a decoded picture.

The size of the syntax element **dpb_output_delay** is given in bits by $\text{dpb_output_delay_length_minus1} + 1$. When **max_dec_frame_buffering** is equal to 0, **dpb_output_delay** shall be equal to 0.

The output time derived from the **dpb_output_delay** of any picture that is output from an output timing conforming decoder as specified in subclause C.2 shall precede the output time derived from the **dpb_output_delay** of all pictures in any subsequent coded video sequence in decoding order.

The output time derived from the **dpb_output_delay** of the second field, in decoding order, of a complementary non-reference field pair shall exceed the output time derived from the **dpb_output_delay** of the first field of the same complementary non-reference field pair.

The picture output order established by the values of this syntax element shall be the same order as established by the values of **PicOrderCnt()** as specified by subclauses C.4.1 to C.4.5, except that when the two fields of a complementary reference field pair have the same value of **PicOrderCnt()**, the two fields have different output times.

For pictures that are not output by the "bumping" process of subclause C.4.5 because they precede, in decoding order, an IDR picture with **no_output_of_prior_pics_flag** equal to 1 or inferred to be equal to 1, the output times derived from **dpb_output_delay** shall be increasing with increasing value of **PicOrderCnt()** relative to all pictures within the same coded video sequence subsequent to any picture having a **memory_management_control_operation** equal to 5.

pic_struct indicates whether a picture should be displayed as a frame or one or more fields, according to Table D-1. Frame doubling (**pic_struct** equal to 7) indicates that the frame should be displayed two times consecutively, and frame tripling (**pic_struct** equal to 8) indicates that the frame should be displayed three times consecutively.

NOTE 3 – Frame doubling can facilitate the display, for example, of 25p video on a 50p display and 29.97p video on a 59.94p display. Using frame doubling and frame tripling in combination on every other frame can facilitate the display of 23.98p video on a 59.94p display.

Table D-1 – Interpretation of pic_struct

Value	Indicated display of picture	Restrictions	NumClockTS
0	frame	field_pic_flag shall be 0	1
1	top field	field_pic_flag shall be 1, bottom_field_flag shall be 0	1
2	bottom field	field_pic_flag shall be 1, bottom_field_flag shall be 1	1
3	top field, bottom field, in that order	field_pic_flag shall be 0	2
4	bottom field, top field, in that order	field_pic_flag shall be 0	2
5	top field, bottom field, top field repeated, in that order	field_pic_flag shall be 0	3
6	bottom field, top field, bottom field repeated, in that order	field_pic_flag shall be 0	3
7	frame doubling	field_pic_flag shall be 0 fixed_frame_rate_flag shall be 1	2
8	frame tripling	field_pic_flag shall be 0 fixed_frame_rate_flag shall be 1	3
9..15	reserved		

NumClockTS is determined by pic_struct as specified in Table D-1. There are up to NumClockTS sets of clock timestamp information for a picture, as specified by clock_timestamp_flag[i] for each set. The sets of clock timestamp information apply to the field(s) or the frame(s) associated with the picture by pic_struct.

The contents of the clock timestamp syntax elements indicate a time of origin, capture, or alternative ideal display. This indicated time is computed as

$$\text{clockTimestamp} = ((\text{hH} * 60 + \text{mM}) * 60 + \text{sS}) * \text{time_scale} + \text{nFrames} * (\text{num_units_in_tick} * (1 + \text{nuit_field_based_flag})) + \text{tOffset}, \quad (\text{D-1})$$

in units of clock ticks of a clock with clock frequency equal to time_scale Hz, relative to some unspecified point in time for which clockTimestamp is equal to 0. Output order and DPB output timing are not affected by the value of clockTimestamp. When two or more frames with pic_struct equal to 0 are consecutive in output order and have equal values of clockTimestamp, the indication is that the frames represent the same content and that the last such frame in output order is the preferred representation.

NOTE 4 – clockTimestamp time indications may aid display on devices with refresh rates other than those well-matched to DPB output times.

clock_timestamp_flag[i] equal to 1 indicates that a number of clock timestamp syntax elements are present and follow immediately. clock_timestamp_flag[i] equal to 0 indicates that the associated clock timestamp syntax elements are not present. When NumClockTS is greater than 1 and clock_timestamp_flag[i] is equal to 1 for more than one value of i, the value of clockTimestamp shall be non-decreasing with increasing value of i.

ct_type indicates the scan type (interlaced or progressive) of the source material as specified in Table D-2.

Two fields of a coded frame may have different values of ct_type.

When clockTimestamp is equal for two fields of opposite parity that are consecutive in output order, both with ct_type equal to 0 (progressive) or ct_type equal to 2 (unknown), the two fields are indicated to have come from the same original progressive frame. Two consecutive fields in output order shall have different values of clockTimestamp when the value of ct_type for either field is 1 (interlaced).

Table D-2 – Mapping of ct_type to source picture scan

Value	Original picture scan
0	progressive
1	interlaced
2	unknown
3	reserved

nuit_field_based_flag is used in calculating clockTimestamp, as specified in Equation D-1.

counting_type specifies the method of dropping values of the n_frames as specified in Table D-3.

Table D-3 – Definition of counting_type values

Value	Interpretation
0	no dropping of n_frames count values and no use of time_offset
1	no dropping of n_frames count values
2	dropping of individual zero values of n_frames count
3	dropping of individual MaxFPS-1 values of n_frames count
4	dropping of the two lowest (value 0 and 1) n_frames counts when seconds_value is equal to 0 and minutes_value is not an integer multiple of 10
5	dropping of unspecified individual n_frames count values
6	dropping of unspecified numbers of unspecified n_frames count values
7..31	reserved

full_timestamp_flag equal to 1 specifies that the n_frames syntax element is followed by seconds_value, minutes_value, and hours_value. full_timestamp_flag equal to 0 specifies that the n_frames syntax element is followed by seconds_flag.

discontinuity_flag equal to 0 indicates that the difference between the current value of clockTimestamp and the value of clockTimestamp computed from the previous clock timestamp in output order can be interpreted as the time difference between the times of origin or capture of the associated frames or fields. discontinuity_flag equal to 1 indicates that the difference between the current value of clockTimestamp and the value of clockTimestamp computed from the previous clock timestamp in output order should not be interpreted as the time difference between the times of origin or capture of the associated frames or fields. When discontinuity_flag is equal to 0, the value of clockTimestamp shall be greater than or equal to all values of clockTimestamp present for the preceding picture in DPB output order.

cnt_dropped_flag specifies the skipping of one or more values of n_frames using the counting method specified by counting_type.

n_frames specifies the value of nFrames used to compute clockTimestamp. n_frames shall be less than

$$\text{MaxFPS} = \text{Ceil}(\text{time_scale} \div \text{num_units_in_tick}) \quad (\text{D-2})$$

NOTE 5 – n_frames is a frame-based counter. For field-specific timing indications, time_offset should be used to indicate a distinct clockTimestamp for each field.

When `counting_type` is equal to 2 and `cnt_dropped_flag` is equal to 1, `n_frames` shall be equal to 1 and the value of `n_frames` for the previous picture in output order shall not be equal to 0 unless `discontinuity_flag` is equal to 1.

NOTE 6 – When `counting_type` is equal to 2, the need for increasingly large magnitudes of `tOffset` in Equation D-1 when using fixed non-integer frame rates (e.g., 12.5 frames per second with `time_scale` equal to 25 and `num_units_in_tick` equal to 2 and `nuit_field_based_flag` equal to 0) can be avoided by occasionally skipping over the value `n_frames` equal to 0 when counting (e.g., counting `n_frames` from 0 to 12, then incrementing `seconds_value` and counting `n_frames` from 1 to 12, then incrementing `seconds_value` and counting `n_frames` from 0 to 12, etc.).

When `counting_type` is equal to 3 and `cnt_dropped_flag` is equal to 1, `n_frames` shall be equal to 0 and the value of `n_frames` for the previous picture in output order shall not be equal to `MaxFPS` – 1 unless `discontinuity_flag` is equal to 1.

NOTE 7 – When `counting_type` is equal to 3, the need for increasingly large magnitudes of `tOffset` in Equation D-1 when using fixed non-integer frame rates (e.g., 12.5 frames per second with `time_scale` equal to 25 and `num_units_in_tick` equal to 2 and `nuit_field_based_flag` equal to 0) can be avoided by occasionally skipping over the value `n_frames` equal to `MaxFPS` when counting (e.g., counting `n_frames` from 0 to 12, then incrementing `seconds_value` and counting `n_frames` from 0 to 11, then incrementing `seconds_value` and counting `n_frames` from 0 to 12, etc.).

When `counting_type` is equal to 4 and `cnt_dropped_flag` is equal to 1, `n_frames` shall be equal to 2 and the specified value of `sS` shall be zero and the specified value of `mM` shall not be an integer multiple of ten and `n_frames` for the previous picture in output order shall not be equal to 0 or 1 unless `discontinuity_flag` is equal to 1.

NOTE 8 – When `counting_type` is equal to 4, the need for increasingly large magnitudes of `tOffset` in Equation D-1 when using fixed non-integer frame rates (e.g., 30000÷1001 frames per second with `time_scale` equal to 60000 and `num_units_in_tick` equal to 1 001 and `nuit_field_based_flag` equal to 1) can be reduced by occasionally skipping over the value `n_frames` equal to `MaxFPS` when counting (e.g., counting `n_frames` from 0 to 29, then incrementing `seconds_value` and counting `n_frames` from 0 to 29, etc., until the `seconds_value` is zero and `minutes_value` is not an integer multiple of ten, then counting `n_frames` from 2 to 29, then incrementing `seconds_value` and counting `n_frames` from 0 to 29, etc.). This counting method is well known in industry and is often referred to as "NTSC drop-frame" counting.

When `counting_type` is equal to 5 or 6 and `cnt_dropped_flag` is equal to 1, `n_frames` shall not be equal to 1 plus the value of `n_frames` for the previous picture in output order modulo `MaxFPS` unless `discontinuity_flag` is equal to 1.

NOTE 9 – When `counting_type` is equal to 5 or 6, the need for increasingly large magnitudes of `tOffset` in Equation D-1 when using fixed non-integer frame rates can be avoided by occasionally skipping over some values of `n_frames` when counting. The specific values of `n_frames` that are skipped are not specified when `counting_type` is equal to 5 or 6.

seconds_flag equal to 1 specifies that `seconds_value` and `minutes_flag` are present when `full_timestamp_flag` is equal to 0. `seconds_flag` equal to 0 specifies that `seconds_value` and `minutes_flag` are not present.

seconds_value specifies the value of `sS` used to compute `clockTimestamp`. The value of `seconds_value` shall be in the range of 0 to 59, inclusive. When `seconds_value` is not present, the previous `seconds_value` in decoding order shall be used as `sS` to compute `clockTimestamp`.

minutes_flag equal to 1 specifies that `minutes_value` and `hours_flag` are present when `full_timestamp_flag` is equal to 0 and `seconds_flag` is equal to 1. `minutes_flag` equal to 0 specifies that `minutes_value` and `hours_flag` are not present.

minutes_value specifies the value of `mM` used to compute `clockTimestamp`. The value of `minutes_value` shall be in the range of 0 to 59, inclusive. When `minutes_value` is not present, the previous `minutes_value` in decoding order shall be used as `mM` to compute `clockTimestamp`.

hours_flag equal to 1 specifies that `hours_value` is present when `full_timestamp_flag` is equal to 0 and `seconds_flag` is equal to 1 and `minutes_flag` is equal to 1.

hours_value specifies the value of `hH` used to compute `clockTimestamp`. The value of `hours_value` shall be in the range of 0 to 23, inclusive. When `hours_value` is not present, the previous `hours_value` in decoding order shall be used as `hH` to compute `clockTimestamp`.

time_offset specifies the value of `tOffset` used to compute `clockTimestamp`. The number of bits used to represent `time_offset` shall be equal to `time_offset_length`. When `time_offset` is not present, the value 0 shall be used as `tOffset` to compute `clockTimestamp`.

D.2.3 Pan-scan rectangle SEI message semantics

The pan-scan rectangle SEI message syntax elements specify the coordinates of a rectangle relative to the cropping rectangle of the sequence parameter set. Each coordinate of this rectangle is specified in units of one-sixteenth sample spacing relative to the luma sampling grid.

pan_scan_rect_id contains an identifying number that may be used to identify the purpose of the pan-scan rectangle (for example, to identify the rectangle as the area to be shown on a particular display device or as the area that contains a particular actor in the scene). The value of `pan_scan_rect_id` shall be in the range of 0 to $2^{32} - 1$, inclusive.

Values of `pan_scan_rect_id` from 0 to 255 and from 512 to $2^{31}-1$ may be used as determined by the application. Values of `pan_scan_rect_id` from 256 to 511 and from 2^{31} to $2^{32}-1$ are reserved for future use by ITU-T | ISO/IEC. Decoders encountering a value of `pan_scan_rect_id` in the range of 256 to 511 or in the range of 2^{31} to $2^{32}-1$ shall ignore (remove from the bitstream and discard) it.

`pan_scan_rect_cancel_flag` equal to 1 indicates that the SEI message cancels the persistence of any previous pan-scan rectangle SEI message in output order. `pan_scan_rect_cancel_flag` equal to 0 indicates that pan-scan rectangle information follows.

`pan_scan_cnt_minus1` specifies the number of pan-scan rectangles that are present in the SEI message. `pan_scan_cnt_minus1` shall be in the range of 0 to 2, inclusive. `pan_scan_cnt_minus1` equal to 0 indicates that a single pan-scan rectangle is present that applies to all fields of the decoded picture. `pan_scan_cnt_minus1` shall be equal to 0 when the current picture is a field. `pan_scan_cnt_minus1` equal to 1 indicates that two pan-scan rectangles are present, the first of which applies to the first field of the picture in output order and the second of which applies to the second field of the picture in output order. `pan_scan_cnt_minus1` equal to 2 indicates that three pan-scan rectangles are present, the first of which applies to the first field of the picture in output order, the second of which applies to the second field of the picture in output order, and the third of which applies to a repetition of the first field as a third field in output order.

`pan_scan_rect_left_offset[i]`, **`pan_scan_rect_right_offset[i]`**, **`pan_scan_rect_top_offset[i]`**, and **`pan_scan_rect_bottom_offset[i]`**, specify, as signed integer quantities in units of one-sixteenth sample spacing relative to the luma sampling grid, the location of the pan-scan rectangle. The values of each of these four syntax elements shall be in the range of -2^{31} to $2^{31}-1$, inclusive.

The pan-scan rectangle is specified, in units of one-sixteenth sample spacing relative to a luma frame sampling grid, as the region with frame horizontal coordinates from $16 * \text{CropUnitX} * \text{frame_crop_left_offset} + \text{pan_scan_rect_left_offset}[i]$ to $16 * (16 * \text{PicWidthInMbs} - \text{CropUnitX} * \text{frame_crop_right_offset}) + \text{pan_scan_rect_right_offset}[i] - 1$ and with vertical coordinates from $16 * \text{CropUnitY} * \text{frame_crop_top_offset} + \text{pan_scan_rect_top_offset}[i]$ to $16 * (16 * \text{PicHeightInMbs} - \text{CropUnitY} * \text{frame_crop_bottom_offset}) + \text{pan_scan_rect_bottom_offset}[i] - 1$, inclusive. The value of $16 * \text{CropUnitX} * \text{frame_crop_left_offset} + \text{pan_scan_rect_left_offset}[i]$ shall be less than or equal to $16 * (16 * \text{PicWidthInMbs} - \text{CropUnitX} * \text{frame_crop_right_offset}) + \text{pan_scan_rect_right_offset}[i] - 1$; and the value of $16 * \text{CropUnitY} * \text{frame_crop_top_offset} + \text{pan_scan_rect_top_offset}[i]$ shall be less than or equal to $16 * (16 * \text{PicHeightInMbs} - \text{CropUnitY} * \text{frame_crop_bottom_offset}) + \text{pan_scan_rect_bottom_offset}[i] - 1$.

When the pan-scan rectangular area includes samples outside of the cropping rectangle, the region outside of the cropping rectangle may be filled with synthesized content (such as black video content or neutral grey video content) for display.

`pan_scan_rect_repetition_period` specifies the persistence of the pan-scan rectangle SEI message and may specify a picture order count interval within which another pan-scan rectangle SEI message with the same value of `pan_scan_rect_id` or the end of the coded video sequence shall be present in the bitstream. The value of `pan_scan_rect_repetition_period` shall be in the range of 0 to 16 384, inclusive. When `pan_scan_cnt_minus1` is greater than 0, `pan_scan_rect_repetition_period` shall not be greater than 1.

`pan_scan_rect_repetition_period` equal to 0 specifies that the pan-scan rectangle information applies to the current decoded picture only.

`pan_scan_rect_repetition_period` equal to 1 specifies that the pan-scan rectangle information persists in output order until any of the following conditions are true.

- A new coded video sequence begins
- A picture in an access unit containing a pan-scan rectangle SEI message with the same value of `pan_scan_rect_id` is output having `PicOrderCnt()` greater than `PicOrderCnt(CurrPic)`.

`pan_scan_rect_repetition_period` equal to 0 or equal to 1 indicates that another pan-scan rectangle SEI message with the same value of `pan_scan_rect_id` may or may not be present.

`pan_scan_rect_repetition_period` greater than 1 specifies that the pan-scan rectangle information persists until any of the following conditions are true.

- A new coded video sequence begins
- A picture in an access unit containing a pan-scan rectangle SEI message with the same value of `pan_scan_rect_id` is output having `PicOrderCnt()` greater than `PicOrderCnt(CurrPic)` and less than or equal to `PicOrderCnt(CurrPic) + pan_scan_rect_repetition_period`.

`pan_scan_rect_repetition_period` greater than 1 indicates that another pan-scan rectangle SEI message with the same value of `pan_scan_rect_id` shall be present for a picture in an access unit that is output having `PicOrderCnt()` greater

than $\text{PicOrderCnt}(\text{CurrPic})$ and less than or equal to $\text{PicOrderCnt}(\text{CurrPic}) + \text{pan_scan_rect_repetition_period}$; unless the bitstream ends or a new coded video sequence begins without output of such a picture.

D.2.4 Filler payload SEI message semantics

This message contains a series of payloadSize bytes of value 0xFF, which can be discarded.

ff_byte shall be a byte having the value 0xFF.

D.2.5 User data registered by ITU-T Rec. T.35 SEI message semantics

This message contains user data registered as specified by ITU-T Rec. T.35, the contents of which are not specified by this Recommendation | International Standard.

itu_t_t35_country_code shall be a byte having a value specified as a country code by ITU-T Rec. T.35 Annex A.

itu_t_t35_country_code_extension_byte shall be a byte having a value specified as a country code by ITU-T Rec. T.35 Annex B.

itu_t_t35_payload_byte shall be a byte containing data registered as specified by ITU-T Rec. T.35.

The ITU-T T.35 terminal provider code and terminal provider oriented code shall be contained in the first one or more bytes of the **itu_t_t35_payload_byte**, in the format specified by the Administration that issued the terminal provider code. Any remaining **itu_t_t35_payload_byte** data shall be data having syntax and semantics as specified by the entity identified by the ITU-T T.35 country code and terminal provider code.

D.2.6 User data unregistered SEI message semantics

This message contains unregistered user data identified by a UUID, the contents of which are not specified by this Recommendation | International Standard.

uuid_iso_iec_11578 shall have a value specified as a UUID according to the procedures of ISO/IEC 11578:1996 Annex A.

user_data_payload_byte shall be a byte containing data having syntax and semantics as specified by the UUID generator.

D.2.7 Recovery point SEI message semantics

The recovery point SEI message assists a decoder in determining when the decoding process will produce acceptable pictures for display after the decoder initiates random access or after the encoder indicates a broken link in the sequence. When the decoding process is started with the access unit in decoding order associated with the recovery point SEI message, all decoded pictures at or subsequent to the recovery point in output order specified in this SEI message are indicated to be correct or approximately correct in content. Decoded pictures produced by random access at or before the picture associated with the recovery point SEI message need not be correct in content until the indicated recovery point, and the operation of the decoding process starting at the picture associated with the recovery point SEI message may contain references to pictures not available in the decoded picture buffer.

In addition, by use of the **broken_link_flag**, the recovery point SEI message can indicate to the decoder the location of some pictures in the bitstream that can result in serious visual artefacts when displayed, even when the decoding process was begun at the location of a previous IDR access unit in decoding order.

NOTE 1 – The **broken_link_flag** can be used by encoders to indicate the location of a point after which the decoding process for the decoding of some pictures may cause references to pictures that, though available for use in the decoding process, are not the pictures that were used for reference when the bitstream was originally encoded (e.g., due to a splicing operation performed during the generation of the bitstream).

The recovery point is specified as a count in units of **frame_num** increments subsequent to the **frame_num** of the current access unit at the position of the SEI message.

NOTE 2 – When HRD information is present in the bitstream, a buffering period SEI message should be associated with the access unit associated with the recovery point SEI message in order to establish initialisation of the HRD buffer model after a random access.

recovery_frame_cnt specifies the recovery point of output pictures in output order. All decoded pictures in output order are indicated to be correct or approximately correct in content starting at the output order position of the reference picture having the **frame_num** equal to the **frame_num** of the VCL NAL units for the current access unit incremented by **recovery_frame_cnt** in modulo **MaxFrameNum** arithmetic. **recovery_frame_cnt** shall be in the range of 0 to **MaxFrameNum** – 1, inclusive.

exact_match_flag indicates whether decoded pictures at and subsequent to the specified recovery point in output order derived by starting the decoding process at the access unit associated with the recovery point SEI message shall be an

exact match to the pictures that would be produced by starting the decoding process at the location of a previous IDR access unit in the NAL unit stream. The value 0 indicates that the match need not be exact and the value 1 indicates that the match shall be exact.

When decoding starts from the location of the recovery point SEI message, all references to not available reference pictures shall be inferred as references to pictures containing only macroblocks coded using Intra macroblock prediction modes and having sample values given by Y samples equal to 128, Cb samples equal to 128, and Cr samples equal to 128 (mid-level grey) for purposes of determining the conformance of the value of `exact_match_flag`.

NOTE 3 – When performing random access, decoders should infer all references to not available reference pictures as references to pictures containing only intra macroblocks and having sample values given by Y equal to 128, Cb equal to 128, and Cr equal to 128 (mid-level grey), regardless of the value of `exact_match_flag`.

When `exact_match_flag` is equal to 0, the quality of the approximation at the recovery point is chosen by the encoding process and is not specified by this Recommendation | International Standard.

`broken_link_flag` indicates the presence or absence of a broken link in the NAL unit stream at the location of the recovery point SEI message and is assigned further semantics as follows.

- If `broken_link_flag` is equal to 1, pictures produced by starting the decoding process at the location of a previous IDR access unit may contain undesirable visual artefacts to the extent that decoded pictures at and subsequent to the access unit associated with the recovery point SEI message in decoding order should not be displayed until the specified recovery point in output order.
- Otherwise (`broken_link_flag` is equal to 0), no indication is given regarding any potential presence of visual artefacts.

Regardless of the value of the `broken_link_flag`, pictures subsequent to the specified recovery point in output order are specified to be correct or approximately correct in content.

NOTE 4 – When a sub-sequence information SEI message is present in conjunction with a recovery point SEI message in which `broken_link_flag` is equal to 1 and when `sub_seq_layer_num` is equal to 0, `sub_seq_id` should be different from the latest `sub_seq_id` for `sub_seq_layer_num` equal to 0 that was decoded prior to the location of the recovery point SEI message. When `broken_link_flag` is equal to 0, the `sub_seq_id` in sub-sequence layer 0 should remain unchanged.

`changing_slice_group_idc` equal to 0 indicates that decoded pictures are correct or approximately correct in content at and subsequent to the recovery point in output order when all macroblocks of the primary coded pictures are decoded within the changing slice group period, i.e., the period between the access unit associated with the recovery point SEI message (inclusive) and the specified recovery point (inclusive) in decoding order. `changing_slice_group_idc` shall be equal to 0 when `num_slice_groups_minus1` is equal to 0 in any primary coded picture within the changing slice group period.

When `changing_slice_group_idc` is equal to 1 or 2, `num_slice_groups_minus1` shall be equal to 1 and the macroblock-to-slice-group map type 3, 4, or 5 shall be applied in each primary coded picture in the changing slice group period.

`changing_slice_group_idc` equal to 1 indicates that within the changing slice group period no sample values outside the decoded macroblocks covered by slice group 0 are used for inter prediction of any macroblock within slice group 0. In addition, `changing_slice_group_idc` equal to 1 indicates that when all macroblocks in slice group 0 within the changing slice group period are decoded, decoded pictures will be correct or approximately correct in content at and subsequent to the specified recovery point in output order regardless of whether any macroblock in slice group 1 within the changing slice group period is decoded.

`changing_slice_group_idc` equal to 2 indicates that within the changing slice group period no sample values outside the decoded macroblocks covered by slice group 1 are used for inter prediction of any macroblock within slice group 1. In addition, `changing_slice_group_idc` equal to 2 indicates that when all macroblocks in slice group 1 within the changing slice group period are decoded, decoded pictures will be correct or approximately correct in content at and subsequent to the specified recovery point in output order regardless of whether any macroblock in slice group 0 within the changing slice group period is decoded.

`changing_slice_group_idc` shall be in the range of 0 to 2, inclusive.

D.2.8 Decoded reference picture marking repetition SEI message semantics

The decoded reference picture marking repetition SEI message is used to repeat the decoded reference picture marking syntax structure that was located in the slice header of an earlier picture in the sequence in decoding order.

`original_idr_flag` shall be equal to 1 when the decoded reference picture marking syntax structure occurred originally in an IDR picture. `original_idr_flag` shall be equal to 0 when the repeated decoded reference picture marking syntax structure did not occur in an IDR picture originally.

original_frame_num shall be equal to the frame_num of the picture where the repeated decoded reference picture marking syntax structure originally occurred. The picture indicated by original_frame_num is the previous coded picture having the specified value of frame_num. The value of original_frame_num used to refer to a picture having a memory_management_control_operation equal to 5 shall be 0.

original_field_pic_flag shall be equal to the field_pic_flag of the picture where the repeated decoded reference picture marking syntax structure originally occurred.

original_bottom_field_flag shall be equal to the bottom_field_flag of the picture where the repeated decoded reference picture marking syntax structure originally occurred.

dec_ref_pic_marking() shall contain a copy of the decoded reference picture marking syntax structure of the picture whose frame_num was original_frame_num. The nal_unit_type used for specification of the repeated dec_ref_pic_marking() syntax structure shall be the nal_unit_type of the slice header(s) of the picture whose frame_num was original_frame_num (i.e., nal_unit_type as used in subclause 7.3.3.3 shall be considered equal to 5 when original_idr_flag is equal to 1 and shall not be considered equal to 5 when original_idr_flag is equal to 0).

D.2.9 Spare picture SEI message semantics

This SEI message indicates that certain slice group map units, called spare slice group map units, in one or more decoded reference pictures resemble the co-located slice group map units in a specified decoded picture called the target picture. A spare slice group map unit may be used to replace a co-located, incorrectly decoded slice group map unit, in the target picture. A decoded picture containing spare slice group map units is called a spare picture.

For all spare pictures identified in a spare picture SEI message, the value of frame_mbs_only_flag shall be equal to the value of frame_mbs_only_flag of the target picture in the same SEI message. The spare pictures in the SEI message are constrained as follows.

- If the target picture is a decoded field, all spare pictures identified in the same SEI message shall be decoded fields.
- Otherwise (the target picture is a decoded frame), all spare pictures identified in the same SEI message shall be decoded frames.

For all spare pictures identified in a spare picture SEI message, the values of pic_width_in_mbs_minus1 and pic_height_in_map_units_minus1 shall be equal to the values of pic_width_in_mbs_minus1 and pic_height_in_map_units_minus1, respectively, of the target picture in the same SEI message. The picture associated (as specified in subclause 7.4.1.2.3) with this message shall appear after the target picture, in decoding order.

target_frame_num indicates the frame_num of the target picture.

spare_field_flag equal to 0 indicates that the target picture and the spare pictures are decoded frames. spare_field_flag equal to 1 indicates that the target picture and the spare pictures are decoded fields.

target_bottom_field_flag equal to 0 indicates that the target picture is a top field. target_bottom_field_flag equal to 1 indicates that the target picture is a bottom field.

A target picture is a decoded reference picture whose corresponding primary coded picture precedes the current picture, in decoding order, and in which the values of frame_num, field_pic_flag (when present) and bottom_field_flag (when present) are equal to target_frame_num, spare_field_flag and target_bottom_field_flag, respectively.

num_spare_pics_minus1 indicates the number of spare pictures for the specified target picture. The number of spare pictures is equal to num_spare_pics_minus1 + 1. The value of num_spare_pics_minus1 shall be in the range of 0 to 15, inclusive.

delta_spare_frame_num[i] is used to identify the spare picture that contains the i-th set of spare slice group map units, hereafter called the i-th spare picture, as specified below. The value of delta_spare_frame_num[i] shall be in the range of 0 to MaxFrameNum - 1 - !spare_field_flag, inclusive.

The frame_num of the i-th spare picture, spareFrameNum[i], is derived as follows for all values of i from 0 to num_spare_pics_minus1, inclusive:

```

candidateSpareFrameNum = target_frame_num - !spare_field_flag
for ( i = 0; i <= num_spare_pics_minus1; i++ ) {
    if( candidateSpareFrameNum < 0 )
        candidateSpareFrameNum = MaxFrameNum - 1
    spareFrameNum[ i ] = candidateSpareFrameNum - delta_spare_frame_num[ i ]
    if( spareFrameNum[ i ] < 0 )
        spareFrameNum[ i ] = MaxFrameNum + spareFrameNum[ i ]
}

```

(D-3)

```

candidateSpareFrameNum = spareFrameNum[ i ] - !spare_field_flag
}

```

spare_bottom_field_flag[i] equal to 0 indicates that the i-th spare picture is a top field. **spare_bottom_field_flag[i]** equal to 1 indicates that the i-th spare picture is a bottom field.

The 0-th spare picture is a decoded reference picture whose corresponding primary coded picture precedes the target picture, in decoding order, and in which the values of **frame_num**, **field_pic_flag** (when present) and **bottom_field_flag** (when present) are equal to **spareFrameNum[0]**, **spare_field_flag** and **spare_bottom_field_flag[0]**, respectively. The i-th spare picture is a decoded reference picture whose corresponding primary coded picture precedes the (i - 1)-th spare picture, in decoding order, and in which the values of **frame_num**, **field_pic_flag** (when present) and **bottom_field_flag** (when present) are equal to **spareFrameNum[i]**, **spare_field_flag** and **spare_bottom_field_flag[i]**, respectively.

spare_area_idc[i] indicates the method used to identify the spare slice group map units in the i-th spare picture. **spare_area_idc[i]** shall be in the range of 0 to 2, inclusive. **spare_area_idc[i]** equal to 0 indicates that all slice group map units in the i-th spare picture are spare units. **spare_area_idc[i]** equal to 1 indicates that the value of the syntax element **spare_unit_flag[i][j]** is used to identify the spare slice group map units. **spare_area_idc[i]** equal to 2 indicates that the **zero_run_length[i][j]** syntax element is used to derive the values of **spareUnitFlagInBoxOutOrder[i][j]**, as described below.

spare_unit_flag[i][j] equal to 0 indicates that the j-th slice group map unit in raster scan order in the i-th spare picture is a spare unit. **spare_unit_flag[i][j]** equal to 1 indicates that the j-th slice group map unit in raster scan order in the i-th spare picture is not a spare unit.

zero_run_length[i][j] is used to derive the values of **spareUnitFlagInBoxOutOrder[i][j]** when **spare_area_idc[i]** is equal to 2. In this case, the spare slice group map units identified in **spareUnitFlagInBoxOutOrder[i][j]** appear in counter-clockwise box-out order, as specified in subclause 8.2.2.4, for each spare picture. **spareUnitFlagInBoxOutOrder[i][j]** equal to 0 indicates that the j-th slice group map unit in counter-clockwise box-out order in the i-th spare picture is a spare unit. **spareUnitFlagInBoxOutOrder[i][j]** equal to 1 indicates that the j-th slice group map unit in counter-clockwise box-out order in the i-th spare picture is not a spare unit.

When **spare_area_idc[0]** is equal to 2, **spareUnitFlagInBoxOutOrder[0][j]** is derived as follows:

```

for( j = 0, loop = 0; j < PicSizeInMapUnits; loop++ ) {
    for( k = 0; k < zero_run_length[ 0 ][ loop ]; k++ )
        spareUnitFlagInBoxOutOrder[ 0 ][ j++ ] = 0
        spareUnitFlagInBoxOutOrder[ 0 ][ j++ ] = 1
}

```

(D-4)

When **spare_area_idc[i]** is equal to 2 and the value of i is greater than 0, **spareUnitFlagInBoxOutOrder[i][j]** is derived as follows:

```

for( j = 0, loop = 0; j < PicSizeInMapUnits; loop++ ) {
    for( k = 0; k < zero_run_length[ i ][ loop ]; k++ )
        spareUnitFlagInBoxOutOrder[ i ][ j ] = spareUnitFlagInBoxOutOrder[ i - 1 ][ j++ ]
        spareUnitFlagInBoxOutOrder[ i ][ j ] = !spareUnitFlagInBoxOutOrder[ i - 1 ][ j++ ]
}

```

(D-5)

D.2.10 Scene information SEI message semantics

A scene and a scene transition are herein defined as a set of consecutive pictures in output order.

NOTE 1 – Decoded pictures within one scene generally have similar content. The scene information SEI message is used to label pictures with scene identifiers and to indicate scene changes. The message specifies how the source pictures for the labelled pictures were created. The decoder may use the information to select an appropriate algorithm to conceal transmission errors. For example, a specific algorithm may be used to conceal transmission errors that occurred in pictures belonging to a gradual scene transition. Furthermore, the scene information SEI message may be used in a manner determined by the application, such as for indexing the scenes of a coded sequence.

A scene information SEI message labels all pictures, in decoding order, from the primary coded picture to which the SEI message is associated (inclusive), as specified in subclause 7.4.1.2.3, to the primary coded picture to which the next scene information SEI message (if present) in decoding order is associated (exclusive) or (otherwise) to the last access unit in the bitstream (inclusive). These pictures are herein referred to as the target pictures.

scene_info_present_flag equal to 0 indicates that the scene or scene transition to which the target pictures belong is unspecified. **scene_info_present_flag** equal to 1 indicates that the target pictures belong to the same scene or scene transition.

scene_id identifies the scene to which the target pictures belong. When the value of **scene_transition_type** of the target pictures is less than 4, and the previous picture in output order is marked with a value of **scene_transition_type** less than 4, and the value of **scene_id** is the same as the value of **scene_id** of the previous picture in output order, this indicates that the source scene for the target pictures and the source scene for the previous picture (in output order) are considered by the encoder to have been the same scene. When the value of **scene_transition_type** of the target pictures is greater than 3, and the previous picture in output order is marked with a value of **scene_transition_type** less than 4, and the value of **scene_id** is the same as the value of **scene_id** of the previous picture in output order, this indicates that one of the source scenes for the target pictures and the source scene for the previous picture (in output order) are considered by the encoder to have been the same scene. When the value of **scene_id** is not equal to the value of **scene_id** of the previous picture in output order, this indicates that the target pictures and the previous picture (in output order) are considered by the encoder to have been from different source scenes.

The value of **scene_id** shall be in the range of 0 to $2^{32}-1$, inclusive. Values of **scene_id** in the range of 0 to 255, inclusive, and in the range of 512 to $2^{31}-1$, inclusive, may be used as determined by the application. Values of **scene_id** in the range of 256 to 511, inclusive, and in the range of 2^{31} to $2^{32}-1$, inclusive, are reserved for future use by ITU-T | ISO/IEC. Decoders encountering a value of **scene_id** in the range of 256 to 511, inclusive, or in the range of 2^{31} to $2^{32}-1$, inclusive, shall ignore (remove from the bitstream and discard) it.

scene_transition_type specifies in which type of a scene transition (if any) the target pictures are involved. The valid values of **scene_transition_type** are specified in Table D-4.

Table D-4 – scene_transition_type values

Value	Description
0	No transition
1	Fade to black
2	Fade from black
3	Unspecified transition from or to constant colour
4	Dissolve
5	Wipe
6	Unspecified mixture of two scenes

When **scene_transition_type** is greater than 3, the target pictures include contents both from the scene labelled by its **scene_id** and the next scene, in output order, which is labelled by **second_scene_id** (see below). The term “the current scene” is used to indicate the scene labelled by **scene_id**. The term “the next scene” is used to indicate the scene labelled by **second_scene_id**. It is not required for any following picture, in output order, to be labelled with **scene_id** equal to **second_scene_id** of the current SEI message.

Scene transition types are specified as follows.

“No transition” specifies that the target pictures are not involved in a gradual scene transition.

NOTE 2 – When two consecutive pictures in output order have **scene_transition_type** equal to 0 and different values of **scene_id**, a scene cut occurred between the two pictures.

“Fade to black” indicates that the target pictures are part of a sequence of pictures, in output order, involved in a fade to black scene transition, i.e., the luma samples of the scene gradually approach zero and the chroma samples of the scene gradually approach 128.

NOTE 3 – When two pictures are labelled to belong to the same scene transition and their **scene_transition_type** is “Fade to black”, the later one, in output order, is darker than the previous one.

“Fade from black” indicates that the target pictures are part of a sequence of pictures, in output order, involved in a fade from black scene transition, i.e., the luma samples of the scene gradually diverge from zero and the chroma samples of the scene may gradually diverge from 128.

NOTE 4 – When two pictures are labelled to belong to the same scene transition and their **scene_transition_type** is “Fade from black”, the later one in output order is lighter than the previous one.

“Dissolve” indicates that the sample values of each target picture (before encoding) were generated by calculating a sum of co-located weighted sample values of a picture from the current scene and a picture from the next scene. The

weight of the current scene gradually decreases from full level to zero level, whereas the weight of the next scene gradually increases from zero level to full level. When two pictures are labelled to belong to the same scene transition and their `scene_transition_type` is "Dissolve", the weight of the current scene for the later one, in output order, is less than the weight of the current scene for the previous one, and the weight of the next scene for the later one, in output order, is greater than the weight of the next scene for the previous one.

"Wipe" indicates that some of the sample values of each target picture (before encoding) were generated by copying co-located sample values of a picture in the current scene and the remaining sample values of each target picture (before encoding) were generated by copying co-located sample values of a picture in the next scene. When two pictures are labelled to belong to the same scene transition and their `scene_transition_type` is "Wipe", the number of samples copied from the next scene to the later picture in output order is greater than the number of samples copied from the next scene to the previous picture.

second_scene_id identifies the next scene in the gradual scene transition in which the target pictures are involved. The value of `second_scene_id` shall not be equal to the value of `scene_id`. The value of `second_scene_id` shall not be equal to the value of `scene_id` in the previous picture in output order. When the next picture in output order is marked with a value of `scene_transition_type` less than 4, and the value of `second_scene_id` is the same as the value of `scene_id` of the next picture in output order, this indicates that the encoder considers one of the source scenes for the target pictures and the source scene for the next picture (in output order) to have been the same scene. When the value of `second_scene_id` is not equal to the value of `scene_id` or `second_scene_id` (if present) of the next picture in output order, this indicates that the encoder considers the target pictures and the next picture (in output order) to have been from different source scenes.

When the value of `scene_id` of a picture is equal to the value of `scene_id` of the following picture in output order and the value of `scene_transition_type` in both of these pictures is less than 4, this indicates that the encoder considers the two pictures to have been from the same source scene. When the values of `scene_id`, `scene_transition_type` and `second_scene_id` (if present) of a picture are equal to the values of `scene_id`, `scene_transition_type` and `second_scene_id` (respectively) of the following picture in output order and the value of `scene_transition_type` is greater than 0, this indicates that the encoder considers the two pictures to have been from the same source gradual scene transition.

The value of `second_scene_id` shall be in the range of 0 to $2^{32}-1$, inclusive. Values of `second_scene_id` in the range of 0 to 255, inclusive, and in the range of 512 to $2^{31}-1$, inclusive, may be used as determined by the application. Values of `second_scene_id` in the range of 256 to 511, inclusive, and in the range of 2^{31} to $2^{32}-1$, inclusive, are reserved for future use by ITU-T | ISO/IEC. Decoders encountering a value of `second_scene_id` in the range of 256 to 511, inclusive, or in the range of 2^{31} to $2^{32}-1$, inclusive, shall ignore (remove from the bitstream and discard) it.

D.2.11 Sub-sequence information SEI message semantics

The sub-sequence information SEI message is used to indicate the position of a picture in data dependency hierarchy that consists of sub-sequence layers and sub-sequences.

A sub-sequence layer contains a subset of the coded pictures in a sequence. Sub-sequence layers are numbered with non-negative integers. A layer having a larger layer number is a higher layer than a layer having a smaller layer number. The layers are ordered hierarchically based on their dependency on each other so that any picture in a layer shall not be predicted from any picture on any higher layer.

NOTE 1 – In other words, any picture in layer 0 must not be predicted from any picture in layer 1 or above, pictures in layer 1 may be predicted from layer 0, pictures in layer 2 may be predicted from layers 0 and 1, etc.

NOTE 2 – The subjective quality is expected to increase along with the number of decoded layers.

A sub-sequence is a set of coded pictures within a sub-sequence layer. A picture shall reside in one sub-sequence layer and in one sub-sequence only. Any picture in a sub-sequence shall not be predicted from any picture in another sub-sequence in the same or in a higher sub-sequence layer. A sub-sequence in layer 0 can be decoded independently of any picture that does not belong to the sub-sequence.

The sub-sequence information SEI message concerns the current access unit. The primary coded picture in the access unit is herein referred to as the current picture.

The sub-sequence information SEI message shall not be present unless `gaps_in_frame_num_value_allowed_flag` in the sequence parameter set referenced by the picture associated with the sub-sequence SEI message is equal to 1.

sub_seq_layer_num specifies the sub-sequence layer number of the current picture. When `sub_seq_layer_num` is greater than 0, memory management control operations shall not be used in any slice header of the current picture. When the current picture resides in a sub-sequence whose first picture in decoding order is an IDR picture, the value of `sub_seq_layer_num` shall be equal to 0. For a non-paired reference field, the value of `sub_seq_layer_num` shall be equal to 0. `sub_seq_layer_num` shall be in the range of 0 to 255, inclusive.

sub_seq_id identifies the sub-sequence within a layer. When the current picture resides in a sub-sequence whose first picture in decoding order is an IDR picture, the value of **sub_seq_id** shall be the same as the value of **idr_pic_id** of the IDR picture. **sub_seq_id** shall be in the range of 0 to 65535, inclusive.

first_ref_pic_flag equal to 1 specifies that the current picture is the first reference picture of the sub-sequence in decoding order. When the current picture is not the first picture of the sub-sequence in decoding order, the **first_ref_pic_flag** shall be equal to 0.

leading_non_ref_pic_flag equal to 1 specifies that the current picture is a non-reference picture preceding any reference picture in decoding order within the sub-sequence or that the sub-sequence contains no reference pictures. When the current picture is a reference picture or the current picture is a non-reference picture succeeding at least one reference picture in decoding order within the sub-sequence, the **leading_non_ref_pic_flag** shall be equal to 0.

last_pic_flag equal to 1 indicates that the current picture is the last picture of the sub-sequence (in decoding order), including all reference and non-reference pictures of the sub-sequence. When the current picture is not the last picture of the sub-sequence (in decoding order), **last_pic_flag** shall be equal to 0.

The current picture is assigned to a sub-sequence as follows.

- If one or more of the following conditions is true, the current picture is the first picture of a sub-sequence in decoding order.
 - no earlier picture in decoding order is labelled with the same values of **sub_seq_id** and **sub_seq_layer_num** as the current picture
 - the value of **leading_non_ref_pic_flag** is equal to 1 and the value of **leading_non_ref_pic_flag** is equal to 0 in the previous picture in decoding order having the same values of **sub_seq_id** and **sub_seq_layer_num** as the current picture
 - the value of **first_ref_pic_flag** is equal to 1 and the value of **leading_non_ref_pic_flag** is equal to 0 in the previous picture in decoding order having the same values of **sub_seq_id** and **sub_seq_layer_num** as the current picture
 - the value of **last_pic_flag** is equal to 1 in the previous picture in decoding order having the same values of **sub_seq_id** and **sub_seq_layer_num** as the current picture
- Otherwise, the current picture belongs to the same sub-sequence as the previous picture in decoding order having the same values of **sub_seq_id** and **sub_seq_layer_num** as the current picture.

sub_seq_frame_num_flag equal to 0 specifies that **sub_seq_frame_num** is not present. **sub_seq_frame_num_flag** equal to 1 specifies that **sub_seq_frame_num** is present.

sub_seq_frame_num shall be equal to 0 for the first reference picture of the sub-sequence and for any non-reference picture preceding the first reference picture of the sub-sequence in decoding order. **sub_seq_frame_num** is further constrained as follows.

- If the current picture is not the second field of a complementary field pair, **sub_seq_frame_num** shall be incremented by 1, in modulo **MaxFrameNum** operation, relative to the previous reference picture, in decoding order, that belongs to the sub-sequence.
- Otherwise (the current picture is the second field of a complementary field pair), the value of **sub_seq_frame_num** shall be the same as the value of **sub_seq_frame_num** for the first field of the complementary field pair.

sub_seq_frame_num shall be in the range of 0 to **MaxFrameNum** – 1, inclusive.

When the current picture is an IDR picture, it shall start a new sub-sequence in sub-sequence layer 0. Thus, the **sub_seq_layer_num** shall be 0, the **sub_seq_id** shall be different from the previous sub-sequence in sub-sequence layer 0, **first_ref_pic_flag** shall be 1, and **leading_non_ref_pic_flag** shall be equal to 0.

When the sub-sequence information SEI message is present for both coded fields of a complementary field pair, the values of **sub_seq_layer_num**, **sub_seq_id**, **leading_non_ref_pic_flag** and **sub_seq_frame_num**, when present, shall be identical for both of these pictures.

When the sub-sequence information SEI message is present only for one coded field of a complementary field pair, the values of **sub_seq_layer_num**, **sub_seq_id**, **leading_non_ref_pic_flag** and **sub_seq_frame_num**, when present, are also applicable to the other coded field of the complementary field pair.

D.2.12 Sub-sequence layer characteristics SEI message semantics

The sub-sequence layer characteristics SEI message specifies the characteristics of sub-sequence layers.

num_sub_seq_layers_minus1 plus 1 specifies the number of sub-sequence layers in the sequence. **num_sub_seq_layers_minus1** shall be in the range of 0 to 255, inclusive.

A pair of **average_bit_rate** and **average_frame_rate** characterizes each sub-sequence layer. The first pair of **average_bit_rate** and **average_frame_rate** specifies the characteristics of sub-sequence layer 0. When present, the second pair specifies the characteristics of sub-sequence layers 0 and 1 jointly. Each pair in decoding order specifies the characteristics for a range of sub-sequence layers from layer number 0 to the layer number specified by the layer loop counter. The values are in effect from the point they are decoded until an update of the values is decoded.

accurate_statistics_flag equal to 1 indicates that the values of **average_bit_rate** and **average_frame_rate** are rounded from statistically correct values. **accurate_statistics_flag** equal to 0 indicates that the **average_bit_rate** and the **average_frame_rate** are estimates and may deviate somewhat from the correct values.

When **accurate_statistics_flag** is equal to 0, the quality of the approximation used in the computation of the values of **average_bit_rate** and the **average_frame_rate** is chosen by the encoding process and is not specified by this Recommendation | International Standard.

average_bit_rate indicates the average bit rate in units of 1000 bits per second. All NAL units in the range of sub-sequence layers specified above are taken into account in the calculation. The average bit rate is derived according to the access unit removal time specified in Annex C of the Recommendation | International Standard. In the following, **bTotal** is the number of bits in all NAL units succeeding a sub-sequence layer characteristics SEI message (including the bits of the NAL units of the current access unit) and preceding the next access unit (in decoding order) including a sub-sequence layer characteristics SEI message (if present) or the end of the stream (otherwise). t_1 is the removal time (in seconds) of the current access unit, and t_2 is the removal time (in seconds) of the latest access unit (in decoding order) before the next sub-sequence layer characteristics SEI message (if present) or the end of the stream (otherwise).

When **accurate_statistics_flag** is equal to 1, the following conditions shall be fulfilled as follows.

- If t_1 is not equal to t_2 , the following condition shall be true

$$\text{average_bit_rate} == \text{Round}(\text{bTotal} \div ((t_2 - t_1) * 1000)) \quad (\text{D-6})$$

- Otherwise (t_1 is equal to t_2), the following condition shall be true

$$\text{average_bit_rate} == 0 \quad (\text{D-7})$$

average_frame_rate indicates the average frame rate in units of frames/(256 seconds). All NAL units in the range of sub-sequence layers specified above are taken into account in the calculation. In the following, **fTotal** is the number of frames, complementary field pairs and non-paired fields between the current picture (inclusive) and the next sub-sequence layer characteristics SEI message (if present) or the end of the stream (otherwise). t_1 is the removal time (in seconds) of the current access unit, and t_2 is the removal time (in seconds) of the latest access unit (in decoding order) before the next sub-sequence layer characteristics SEI message (if present) or the end of the stream (otherwise).

When **accurate_statistics_flag** is equal to 1, the following conditions shall be fulfilled as follows.

- If t_1 is not equal to t_2 , the following condition shall be true

$$\text{average_frame_rate} == \text{Round}(\text{fTotal} * 256 \div (t_2 - t_1)) \quad (\text{D-8})$$

- Otherwise (t_1 is equal to t_2), the following condition shall be true

$$\text{average_frame_rate} == 0 \quad (\text{D-9})$$

D.2.13 Sub-sequence characteristics SEI message semantics

The sub-sequence characteristics SEI message indicates the characteristics of a sub-sequence. It also indicates inter prediction dependencies between sub-sequences. This message shall be contained in the first access unit in decoding order of the sub-sequence to which the sub-sequence characteristics SEI message applies. This sub-sequence is herein called the target sub-sequence.

sub_seq_layer_num identifies the sub-sequence layer number of the target sub-sequence. **sub_seq_layer_num** shall be in the range of 0 to 255, inclusive.

sub_seq_id identifies the target sub-sequence. **sub_seq_id** shall be in the range of 0 to 65535, inclusive.

duration_flag equal to 0 indicates that the duration of the target sub-sequence is not specified.

sub_seq_duration specifies the duration of the target sub-sequence in clock ticks of a 90-kHz clock.

average_rate_flag equal to 0 indicates that the average bit rate and the average frame rate of the target sub-sequence are unspecified.

accurate_statistics_flag indicates how reliable the values of **average_bit_rate** and **average_frame_rate** are. **accurate_statistics_flag** equal to 1, indicates that the **average_bit_rate** and the **average_frame_rate** are rounded from statistically correct values. **accurate_statistics_flag** equal to 0 indicates that the **average_bit_rate** and the **average_frame_rate** are estimates and may deviate from the statistically correct values.

average_bit_rate indicates the average bit rate in (1000 bits)/second of the target sub-sequence. All NAL units of the target sub-sequence are taken into account in the calculation. The average bit rate is derived according to the access unit removal time specified in subclause C.1.2. In the following, nB is the number of bits in all NAL units in the sub-sequence. t_1 is the removal time (in seconds) of the first access unit of the sub-sequence (in decoding order), and t_2 is the removal time (in seconds) of the last access unit of the sub-sequence (in decoding order).

When **accurate_statistics_flag** is equal to 1, the following conditions shall be fulfilled as follows.

- If t_1 is not equal to t_2 , the following condition shall be true

$$\text{average_bit_rate} == \text{Round}(nB \div ((t_2 - t_1) * 1000)) \quad (D-10)$$

- Otherwise (t_1 is equal to t_2), the following condition shall be true

$$\text{average_bit_rate} == 0 \quad (D-11)$$

average_frame_rate indicates the average frame rate in units of frames/(256 seconds) of the target sub-sequence. All NAL units of the target sub-sequence are taken into account in the calculation. The average frame rate is derived according to the access unit removal time specified in subclause C.1.2. In the following, fC is the number of frames, complementary field pairs and non-paired fields in the sub-sequence. t_1 is the removal time (in seconds) of the first access unit of the sub-sequence (in decoding order), and t_2 is the removal time (in seconds) of the last access unit of the sub-sequence (in decoding order).

When **accurate_statistics_flag** is equal to 1, the following conditions shall be fulfilled as follows.

- If t_1 is not equal to t_2 , the following condition shall be true

$$\text{average_frame_rate} == \text{Round}(fC * 256 \div (t_2 - t_1)) \quad (D-12)$$

- Otherwise (t_1 is equal to t_2), the following condition shall be true

$$\text{average_frame_rate} == 0 \quad (D-13)$$

num_referenced_subseqs specifies the number of sub-sequences that contain pictures that are used as reference pictures for inter prediction in the pictures of the target sub-sequence. **num_referenced_subseqs** shall be in the range of 0 to 255, inclusive.

ref_sub_seq_layer_num, **ref_sub_seq_id**, and **ref_sub_seq_direction** identify the sub-sequence that contains pictures that are used as reference pictures for inter prediction in the pictures of the target sub-sequence. Depending on **ref_sub_seq_direction**, the following applies.

- If **ref_sub_seq_direction** is equal to 0, a set of candidate sub-sequences consists of the sub-sequences whose **sub_seq_id** is equal to **ref_sub_seq_id**, which reside in the sub-sequence layer having **sub_seq_layer_num** equal to **ref_sub_seq_layer_num**, and whose first picture in decoding order precedes the first picture of the target sub-sequence in decoding order.
- Otherwise (**ref_sub_seq_direction** is equal to 1), a set of candidate sub-sequences consists of the sub-sequences whose **sub_seq_id** is equal to **ref_sub_seq_id**, which reside in the sub-sequence layer having **sub_seq_layer_num** equal to **ref_sub_seq_layer_num**, and whose first picture in decoding order succeeds the first picture of the target sub-sequence in decoding order.

The sub-sequence used as a reference for the target sub-sequence is the sub-sequence among the set of candidate sub-sequences whose first picture is the closest to the first picture of the target sub-sequence in decoding order.

D.2.14 Full-frame freeze SEI message semantics

The full-frame freeze SEI message indicates that the current picture and any subsequent pictures in output order that meet specified conditions should not affect the content of the display. No more than one full-frame freeze SEI message shall be present in any access unit.

full_frame_freeze_repetition_period specifies the persistence of the full-frame freeze SEI message and may specify a picture order count interval within which another full-frame freeze SEI message or a full-frame freeze release SEI or the end of the coded video sequence shall be present in the bitstream. The value of **full_frame_freeze_repetition_period** shall be in the range of 0 to 16 384, inclusive.

full_frame_freeze_repetition_period equal to 0 specifies that the full-frame freeze SEI message applies to the current decoded picture only.

full_frame_freeze_repetition_period equal to 1 specifies that the full-frame freeze SEI message persists in output order until any of the following conditions are true.

- A new coded video sequence begins
- A picture in an access unit containing a full-frame freeze SEI message or a full-frame freeze release SEI message is output having **PicOrderCnt()** greater than **PicOrderCnt(CurrPic)**.

full_frame_freeze_repetition_period greater than 1 specifies that the full-frame freeze SEI message persists until any of the following conditions are true.

- A new coded video sequence begins
- A picture in an access unit containing a full-frame freeze SEI message or a full-frame freeze release SEI message is output having **PicOrderCnt()** greater than **PicOrderCnt(CurrPic)** and less than or equal to **PicOrderCnt(CurrPic) + full_frame_freeze_repetition_period**.

full_frame_freeze_repetition_period greater than 1 indicates that another full-frame freeze SEI message or a full-frame freeze release SEI message shall be present for a picture in an access unit that is output having **PicOrderCnt()** greater than **PicOrderCnt(CurrPic)** and less than or equal to **PicOrderCnt(CurrPic) + full_frame_freeze_repetition_period**; unless the bitstream ends or a new coded video sequence begins without output of such a picture.

D.2.15 Full-frame freeze release SEI message semantics

The full-frame freeze release SEI message cancels the effect of any full-frame freeze SEI message sent with pictures that precede the current picture in output order. The full-frame freeze release SEI message indicates that the current picture and subsequent pictures in output order should affect the contents of the display.

No more than one full-frame freeze release SEI message shall be present in any access unit. A full-frame freeze release SEI message shall not be present in an access unit containing a full-frame freeze SEI message. When a full-frame freeze SEI message is present in an access unit containing a field of a complementary field pair in which the values of **PicOrderCnt(CurrPic)** for the two fields of the complementary field pair are equal to each other, a full-frame freeze release SEI message shall not be present in either of the two access units.

D.2.16 Full-frame snapshot SEI message semantics

The full-frame snapshot SEI message indicates that the current frame is labelled for use as determined by the application as a still-image snapshot of the video content.

snapshot_id specifies a snapshot identification number. **snapshot_id** shall be in the range of 0 to $2^{32} - 1$, inclusive.

Values of **snapshot_id** in the range of 0 to 255, inclusive, and in the range of 512 to $2^{31} - 1$, inclusive, may be used as determined by the application. Values of **snapshot_id** in the range of 256 to 511, inclusive, and in the range of 2^{31} to $2^{32} - 1$, inclusive, are reserved for future use by ITU-T | ISO/IEC. Decoders encountering a value of **snapshot_id** in the range of 256 to 511, inclusive, or in the range of 2^{31} to $2^{32} - 1$, inclusive, shall ignore (remove from the bitstream and discard) it.

D.2.17 Progressive refinement segment start SEI message semantics

The progressive refinement segment start SEI message specifies the beginning of a set of consecutive coded pictures that is labelled as the current picture followed by a sequence of one or more pictures of refinement of the quality of the current picture, rather than as a representation of a continually moving scene.

The tagged set of consecutive coded pictures shall continue until one of the following conditions is true. When a condition below becomes true, the next slice to be decoded does not belong to the tagged set of consecutive coded pictures.

1. The next slice to be decoded belongs to an IDR picture.

2. `num_refinement_steps_minus1` is greater than 0 and the `frame_num` of the next slice to be decoded is $(\text{currFrameNum} + \text{num_refinement_steps_minus1} + 1) \% \text{MaxFrameNum}$, where `currFrameNum` is the value of `frame_num` of the picture in the access unit containing the SEI message.
3. `num_refinement_steps_minus1` is 0 and a progressive refinement segment end SEI message with the same `progressive_refinement_id` as the one in this SEI message is decoded.

The decoding order of picture within the tagged set of consecutive pictures should be the same as their output order. **progressive_refinement_id** specifies an identification number for the progressive refinement operation. `progressive_refinement_id` shall be in the range of 0 to $2^{32} - 1$, inclusive.

Values of `progressive_refinement_id` in the range of 0 to 255, inclusive, and in the range of 512 to $2^{31} - 1$, inclusive, may be used as determined by the application. Values of `progressive_refinement_id` in the range of 256 to 511, inclusive, and in the range of 2^{31} to $2^{32} - 1$, inclusive, are reserved for future use by ITU-T | ISO/IEC. Decoders encountering a value of `progressive_refinement_id` in the range of 256 to 511, inclusive, or in the range of 2^{31} to $2^{32} - 1$, inclusive, shall ignore (remove from the bitstream and discard) it.

num_refinement_steps_minus1 specifies the number of reference frames in the tagged set of consecutive coded pictures as follows.

- If `num_refinement_steps_minus1` is equal to 0, the number of reference frames in the tagged set of consecutive coded pictures is unknown.
- Otherwise, the number of reference frames in the tagged set of consecutive coded pictures is equal to `num_refinement_steps_minus1 + 1`.

`num_refinement_steps_minus1` shall be in the range of 0 to `MaxFrameNum - 1`, inclusive.

D.2.18 Progressive refinement segment end SEI message semantics

The progressive refinement segment end SEI message specifies the end of a set of consecutive coded pictures that has been labelled by use of a progressive refinement segment start SEI message as an initial picture followed by a sequence of one or more pictures of the refinement of the quality of the initial picture, and ending with the current picture.

progressive_refinement_id specifies an identification number for the progressive refinement operation. `progressive_refinement_id` shall be in the range of 0 to $2^{32} - 1$, inclusive.

The progressive refinement segment end SEI message specifies the end of any progressive refinement segment previously started using a progressive refinement segment start SEI message with the same value of `progressive_refinement_id`.

Values of `progressive_refinement_id` in the range of 0 to 255, inclusive, and in the range of 512 to $2^{31} - 1$, inclusive, may be used as determined by the application. Values of `progressive_refinement_id` in the range of 256 to 511, inclusive, and in the range of 2^{31} to $2^{32} - 1$, inclusive, are reserved for future use by ITU-T | ISO/IEC. Decoders encountering a value of `progressive_refinement_id` in the range of 256 to 511, inclusive, or in the range of 2^{31} to $2^{32} - 1$, inclusive, shall ignore (remove from the bitstream and discard) it.

D.2.19 Motion-constrained slice group set SEI message semantics

This SEI message indicates that inter prediction over slice group boundaries is constrained as specified below. When present, the message shall only appear where it is associated, as specified in subclause 7.4.1.2.3, with an IDR access unit.

The target picture set for this SEI message contains all consecutive primary coded pictures in decoding order starting with the associated primary coded IDR picture (inclusive) and ending with the following primary coded IDR picture (exclusive) or with the very last primary coded picture in the bitstream (inclusive) in decoding order when there is no following primary coded IDR picture. The slice group set is a collection of one or more slice groups, identified by the `slice_group_id[i]` syntax element.

This SEI message indicates that, for each picture in the target picture set, the inter prediction process is constrained as follows: No sample value outside the slice group set, and no sample value at a fractional sample position that is derived using one or more sample values outside the slice group set is used to inter predict any sample within the slice group set.

num_slice_groups_in_set_minus1 + 1 specifies the number of slice groups in the slice group set. The allowed range of `num_slice_groups_in_set_minus1` is 0 to `num_slice_groups_minus1`, inclusive. The allowed range of `num_slice_groups_minus1` is specified in Annex A.

slice_group_id[i] identifies the slice group(s) contained within the slice group set. The allowed range is from 0 to num_slice_groups_in_set_minus1, inclusive. The size of the slice_group_id[i] syntax element is $\text{Ceil}(\text{Log2}(\text{num_slice_groups_minus1} + 1))$ bits.

exact_sample_value_match_flag equal to 0 indicates that, within the target picture set, when the macroblocks that do not belong to the slice group set are not decoded, the value of each sample in the slice group set need not be exactly the same as the value of the same sample when all the macroblocks are decoded. **exact_sample_value_match_flag** equal to 1 indicates that, within the target picture set, when the macroblocks that do not belong to the slice group set are not decoded, the value of each sample in the slice group set shall be exactly the same as the value of the same sample when all the macroblocks in the target picture set are decoded.

NOTE 1 – When **disable_deblocking_filter_idc** is equal to 2 in all slices in the target picture set, **exact_sample_value_match_flag** should be 1.

pan_scan_rect_flag equal to 0 specifies that **pan_scan_rect_id** is not present. **pan_scan_rect_flag** equal to 1 specifies that **pan_scan_rect_id** is present.

pan_scan_rect_id indicates that the specified slice group set covers at least the pan-scan rectangle identified by **pan_scan_rect_id** within the target picture set.

NOTE 2 – Multiple **motion_constrained_slice_group_set** SEI messages may be associated with the same IDR picture. Consequently, more than one slice group set may be active within a target picture set.

NOTE 3 – The size, shape, and location of the slice groups in the slice group set may change within the target picture set.

D.2.20 Film grain characteristics SEI message semantics

This SEI message provides the decoder with a parameterised model for film grain synthesis. For example, an encoder may use the film grain characteristics SEI message to characterise film grain that was present in the original source video material and was removed by pre-processing filtering techniques. Synthesis of simulated film grain on the decoded images for the display process is optional and does not affect the decoding process specified in this Recommendation | International Standard. If synthesis of simulated film grain on the decoded images for the display process is performed, there is no requirement that the method by which the synthesis is performed be the same as the parameterised model for the film grain as provided in the film grain characteristics SEI message.

NOTE 1 – The display process is not specified in this Recommendation | International Standard.

film_grain_characteristics_cancel_flag equal to 1 indicates that the SEI message cancels the persistence of any previous film grain characteristics SEI message in output order. **film_grain_characteristics_cancel_flag** equal to 0 indicates that film grain modelling information follows.

model_id identifies the film grain simulation model as specified in Table D-5. The value of **model_id** shall be in the range of 0 to 1, inclusive.

Table D-5 – model_id values

Value	Description
0	frequency filtering
1	auto-regression
2	reserved
3	reserved

separate_colour_description_present_flag equal to 1 indicates that a distinct colour space description for the film grain characteristics specified in the SEI message is present in the film grain characteristics SEI message syntax. **separate_colour_description_present_flag** equal to 0 indicates that the colour description for the film grain characteristics specified in the SEI message is the same as for the coded video sequence as specified in subclause E.2.1.

NOTE 2 – When **separate_colour_description_present_flag** is equal to 1, the colour space specified for the film grain characteristics specified in the SEI message may differ from the colour space specified for the coded video as specified in subclause E.2.1.

film_grain_bit_depth_luma_minus8 plus 8 specifies the bit depth used for the luma component of the film grain characteristics specified in the SEI message. When **film_grain_bit_depth_luma_minus8** is not present in the film grain characteristics SEI message, the value of **film_grain_bit_depth_luma_minus8** shall be inferred to be equal to **bit_depth_luma_minus8**.

The value of **filmGrainBitDepth[0]** is derived as

$$\text{filmGrainBitDepth}[0] = \text{film_grain_bit_depth_luma_minus8} + 8 \quad (\text{D-14})$$

film_grain_bit_depth_chroma_minus8 plus 8 specifies the bit depth used for the Cb and Cr components of the film grain characteristics specified in the SEI message. When **film_grain_bit_depth_chroma_minus8** is not present in the film grain characteristics SEI message, the value of **film_grain_bit_depth_chroma_minus8** shall be inferred to be equal to **bit_depth_chroma_minus8**.

The value of **filmGrainBitDepth[c]** for **c = 1** and **2** is derived as

$$\text{filmGrainBitDepth}[c] = \text{film_grain_bit_depth_chroma_minus8} + 8 \quad \text{with } c = 1, 2 \quad (\text{D-15})$$

film_grain_full_range_flag has the same semantics as specified in subclause E.2.1 for the **video_full_range_flag** syntax element, except as follows.

- **film_grain_full_range_flag** specifies the colour space of the film grain characteristics specified in the SEI message, rather than the colour space used for the coded video sequence.
- When **film_grain_full_range_flag** is not present in the film grain characteristics SEI message, the value of **film_grain_full_range_flag** shall be inferred to be equal to **video_full_range_flag**.

film_grain_colour_primaries has the same semantics as specified in subclause E.2.1 for the **colour_primaries** syntax element, except as follows.

- **film_grain_colour_primaries** specifies the colour space of the film grain characteristics specified in the SEI message, rather than the colour space used for the coded video sequence.
- When **film_grain_colour_primaries** is not present in the film grain characteristics SEI message, the value of **film_grain_colour_primaries** shall be inferred to be equal to **colour_primaries**.

film_grain_transfer_characteristics has the same semantics as specified in subclause E.2.1 for the **transfer_characteristics** syntax element, except as follows.

- **film_grain_transfer_characteristics** specifies the colour space of the film grain characteristics specified in the SEI message, rather than the colour space used for the coded video sequence.
- When **film_grain_transfer_characteristics** is not present in the film grain characteristics SEI message, the value of **film_grain_transfer_characteristics** shall be inferred to be equal to **transfer_characteristics**.

film_grain_matrix_coefficients has the same semantics as specified in subclause E.2.1 for the **matrix_coefficients** syntax element, except as follows.

- **film_grain_matrix_coefficients** specifies the colour space of the film grain characteristics specified in the SEI message, rather than the colour space used for the coded video sequence.
- When **film_grain_matrix_coefficients** is not present in the film grain characteristics SEI message, the value of **film_grain_matrix_coefficients** shall be inferred to be equal to **matrix_coefficients**.
- The values allowed for **film_grain_matrix_coefficients** are not constrained by the value of **chroma_format_idc**.

The **chroma_format_idc** of the film grain characteristics specified in the film grain characteristics SEI message shall be inferred to be equal to 3 (4:4:4).

NOTE 3 – Because the use of a specific method is not required for performing film grain generation function used by the display process, a decoder may, if desired, down-convert the model information for chroma in order to simulate film grain for other chroma formats (4:2:0 or 4:2:2) rather than up-converting the decoded video (using a method not specified by this Recommendation | International Standard) before performing film grain generation.

blending_mode_id identifies the blending mode used to blend the simulated film grain with the decoded images as specified in Table D-6. **blending_mode_id** shall be in the range of 0 to 1, inclusive.

Table D-6 – blending_mode_id values

Value	Description
0	additive
1	multiplicative
2	reserved
3	reserved

Depending on `blending_mode_id`, the blending mode is specified as follows

- If `blending_mode_id` is equal to 0 the blending mode is additive as specified by

$$I_{\text{grain}}[x, y, c] = \text{Clip3}(0, (1 \ll \text{filmGrainBitDepth}[c]) - 1, I_{\text{decoded}}[x, y, c] + G[x, y, c]) \quad (\text{D-16})$$

- Otherwise (`blending_mode_id` is equal to 1), the blending mode is multiplicative as specified by

$$I_{\text{grain}}[x, y, c] = \text{Clip3}(0, (1 \ll \text{filmGrainBitDepth}[c]) - 1, I_{\text{decoded}}[x, y, c] * (1 + G[x, y, c])) \quad (\text{D-17})$$

where $I_{\text{decoded}}[x, y, c]$ represents the sample value at coordinates x, y of the colour component c of the decoded image I_{decoded} , $G[x, y, c]$ is the simulated film grain value at the same position and colour component, and $\text{filmGrainBitDepth}[c]$ is the number of bits used for each sample in a fixed-length unsigned binary representation of the array $I_{\text{grain}}[x, y, c]$.

log2_scale_factor specifies a scale factor used in the film grain characterization equations.

comp_model_present_flag[c] equal to 0 indicates that film grain is not modelled on the c -th colour component, where c equal to 0 refers to the luma component, c equal to 1 refers to the Cb component, and c equal to 2 refers to the Cr component. **comp_model_present_flag**[c] equal to 1 indicates that syntax elements specifying modelling of film grain on colour component c are present in the SEI message.

num_intensity_intervals_minus1[c] plus 1 specifies the number of intensity intervals for which a specific set of model values has been estimated.

NOTE 4 – The intensity intervals may overlap in order to simulate multi-generational film grain.

num_model_values_minus1[c] plus 1 specifies the number of model values present for each intensity interval in which the film grain has been modelled. The value of **num_model_values_minus1**[c] shall be in the range of 0 to 5, inclusive.

intensity_interval_lower_bound[c][i] specifies the lower bound of the interval i of intensity levels for which the set of model values applies.

intensity_interval_upper_bound[c][i] specifies the upper bound of the interval i of intensity levels for which the set of model values applies.

Depending on `model_id`, the selection of the sets of model values is specified as follows.

- If `model_id` is equal to 0, the average value of each block b of 16x16 samples in I_{decoded} , referred as b_{avg} , is used to select the sets of model values with index $s[j]$ that apply to all the samples in the block:

```
for( i = 0, j = 0; i <= num_intensity_intervals_minus1; i++ )
    if( b_avg >= intensity_interval_lower_bound[ c ][ i ] && b_avg <= intensity_interval_upper_bound[ c ][ i ] ) {
        s[ j ] = i
        j++
    }
```

(D-18)

- Otherwise (`model_id` is equal to 1), the sets of model values used to generate the film grain are selected for each sample value in I_{decoded} as follows:

```
for( i = 0, j = 0; i <= num_intensity_intervals_minus1; i++ )
    if( I_decoded[ x, y, c ] >= intensity_interval_lower_bound[ c ][ i ] &&
        I_decoded[ x, y, c ] <= intensity_interval_upper_bound[ c ][ i ] ) {
        s[ j ] = i
        j++
    }
```

(D-19)

Samples that do not fall into any of the defined intervals are not modified by the grain generation function. Samples that fall into more than one interval will originate multi-generation grain. Multi-generation grain results from adding the grain computed independently for each intensity interval.

NOTE 6 – Coded model values are based on blocks of 16x16, but a decoder implementation may use other block sizes. For example, decoders implementing the IDCT on 8x8 blocks, should down-convert by a factor of two the set of coded model values comp_model_value[c][s][i] for i equal to 1..4.

NOTE 7 – To reduce the degree of visible blocks that can result from mosaicing the frequency-filtered blocks filteredRV, decoders may apply a low-pass filter to the boundaries between frequency-filtered blocks.

Q[c] is formed by the frequency-filtered blocks filteredRV.

where Cos(x) is the trigonometric cosine function operating on an argument x in units of radians and π is Archimedes' constant 3.141 592 653.

$$r_{ij} = \frac{4}{((i == 0) ? 1 : \sqrt{2})} \cos\left(\frac{i * (2 * j + 1) * \pi}{32}\right) \quad (\text{D-24})$$

where the superscript T indicates a matrix transposition and r is the 16x16 matrix with elements r_{ij} specified by

$$\text{IDCT16x16}(z) = r * z * r^T \quad (\text{D-23})$$

where IDCT16x16(z) refers to a unitary inverse discrete cosine transformation (IDCT) operating on a 16x16 matrix argument z as specified by

$$\begin{aligned} \text{filteredRV} &= \text{IDCT16x16}(\text{gaussRV}) \\ \text{gaussRV}[x, y] &= 0 \\ \text{if}((x < \text{comp_model_value}[c][s][3] \ \&\& \ y < \text{comp_model_value}[c][s][4]) \ || \\ \text{for}(x = 0; x < 16; x++) \\ \text{for}(y = 0; y < 16; y++) \end{aligned} \quad (\text{D-22})$$

follows:

The band-pass filtering of blocks gaussRV may be performed in the discrete cosine transform (DCT) domain as follows:

where Ln(x) is the natural logarithm of x (the base-e logarithm, where e is natural logarithm base constant 2.718 281 828...), Cos(x) is the trigonometric cosine function operating on an argument x in units of radians, and π is Archimedes' constant 3.141 592 653....

$$\text{gaussRV}_{ij} = \sqrt{-2 * \text{Ln}(\text{uRV}_0) * \text{Cos}(2 * \pi * \text{uRV}_i)} \quad (\text{D-21})$$

NOTE 5 – A normalized Gaussian random value can be generated from two independent, uniformly distributed random values over the interval from 0 to 1 (and not equal to 0), denoted as uRV₀ and uRV₁, using the Box-Muller transformation specified by

where Q[c] is a two-dimensional random process generated by filtering 16x16 blocks gaussRV with random-value elements gaussRV_{ij} generated with a normalized Gaussian distribution (independent and identically distributed Gaussian random variable samples with zero mean and unity variance) and where the value of an element G[x, y, c-1] used in the right-hand side of the equation is inferred to be equal to 0 when c-1 is less than 0.

$$G[x, y, c] = (\text{comp_model_value}[c][s][0] * Q[x, y, c] + \text{comp_model_value}[c][s][5]) * \log_2\text{-scale_factor} \quad (\text{D-20})$$

– If model_id is equal to 0, a frequency filtering model enables simulating the original film grain for c = 0..2, x = 0..PicWidthInSamples_L, and y = 0..PicHeightInSamples_L as specified by:

Depending on model_id, the synthesis of the film grain is modelled as follows.

- Otherwise (model_id is equal to 1), comp_model_value[c][i][j] shall be in the range of $-2^{(\text{filmGrainBitDepth}[c] - 1)}$ to $2^{(\text{filmGrainBitDepth}[c] - 1)}$ – 1, inclusive.
- If model_id is equal to 0, comp_model_value[c][i][j] shall be in the range of 0 to $2^{(\text{filmGrainBitDepth}[c] - 1)}$ – 1, inclusive.

elsewhere in this subclause.

comp_model_value[c][i][j] represents each one of the model values present for the colour component c and the intensity interval i. The set of model values has different meaning depending on the value of model_id. The value of comp_model_value[c][i][j] shall be constrained as follows, and may be additionally constrained as specified

- Otherwise (model_id is equal to 1), an auto-regression model enables simulating the original film grain for $c = 0..2$, $x = 0..PicWidthInSamples_L$, and $y = 0..PicHeightInSamples_L$ as specified by

$$\begin{aligned}
 G[x, y, c] = & (comp_model_value[c][s][0] * n[x, y, c] + \\
 & comp_model_value[c][s][1] * (G[x-1, y, c] + ((comp_model_value[c][s][4] * G[x, y-1, c]) >> \\
 & \log2_scale_factor)) + \\
 & comp_model_value[c][s][3] * ((comp_model_value[c][s][4] * G[x-1, y-1, c]) >> \\
 & \log2_scale_factor) + G[x+1, y-1, c]) + \\
 & comp_model_value[c][s][5] * (G[x-2, y, c] + \\
 & ((comp_model_value[c][s][4] * comp_model_value[c][s][4] * G[x, y-2, c]) >> \\
 & (2 * \log2_scale_factor))) + \\
 & comp_model_value[c][s][2] * G[x, y, c-1]) >> \log2_scale_factor
 \end{aligned} \tag{D-25}$$

where $n[x, y, c]$ is a random value with normalized Gaussian distribution (independent and identically distributed Gaussian random variable samples with zero mean and unity variance for each value of x , y , and c) and where the value of an element $G[x, y, c]$ used in the right-hand side of the equation is inferred to be equal to 0 when any of the following conditions are true:

- x is less than 0,
- y is less than 0,
- x is greater than or equal to $PicWidthInSamples_L$,
- c is less than 0.

comp_model_value[c][i][0] provides the first model value for the model as specified by model_id. **comp_model_value[c][i][0]** corresponds to the standard deviation of the Gaussian noise term in the generation functions specified in Equations D-20 through D-23.

comp_model_value[c][i][1] provides the second model value for the model as specified by model_id. **comp_model_value[c][i][1]** shall be greater than or equal to 0 and less than 16.

When not present in the film grain characteristics SEI message, **comp_model_value[c][i][1]** shall be inferred as follows.

- If model_id is equal to 0, **comp_model_value[c][i][1]** shall be inferred to be equal to 8.
- Otherwise (model_id is equal to 1), **comp_model_value[c][i][1]** shall be inferred to be equal to 0.

comp_model_value[c][i][1] is interpreted as follows.

- If model_id is equal to 0, **comp_model_value[c][i][1]** indicates the horizontal high cut frequency to be used to filter the DCT of a block of 16x16 random values.
- Otherwise (model_id is equal to 1), **comp_model_value[c][i][1]** indicates the first order spatial correlation for neighbouring samples $(x-1, y)$ and $(x, y-1)$.

comp_model_value[c][i][2] provides the third model value for the model as specified by model_id. **comp_model_value[c][i][2]** shall be greater than or equal to 0 and less than 16.

When not present in the film grain characteristics SEI message, **comp_model_value[c][i][2]** shall be inferred as follows.

- If model_id is equal to 0, **comp_model_value[c][i][2]** shall be inferred to be equal to **comp_model_value[c][i][1]**
- Otherwise (model_id is equal to 1), **comp_model_value[c][i][2]** shall be inferred to be equal to 0.

comp_model_value[c][i][2] is interpreted as follows.

- If model_id is equal to 0, **comp_model_value[c][i][2]** indicates the vertical high cut frequency to be used to filter the DCT of a block of 16x16 random values.
- Otherwise (model_id is equal to 1), **comp_model_value[c][i][2]** indicates the colour correlation between consecutive colour components.

comp_model_value[c][i][3] provides the fourth model value for the model as specified by model_id. **comp_model_value[c][i][3]** shall be greater than or equal to 0 and less than or equal to **comp_model_value[c][i][1]**.

When not present in the film grain characteristics SEI message, **comp_model_value[c][i][3]** shall be inferred to be equal to 0.

comp_model_value[c][i][3] is interpreted as follows.

- If model_id is equal to 0, comp_model_value[c][i][3] indicates the horizontal low cut frequency to be used to filter the DCT of a block of 16x16 random values.
- Otherwise (model_id is equal to 1), comp_model_value[c][i][3] indicates the first order spatial correlation for neighbouring samples (x-1, y-1) and (x+1, y-1).

comp_model_value[c][i][4] provides the fifth model value for the model as specified by model_id. comp_model_value[c][i][4] shall be greater than or equal to 0 and less than or equal to comp_model_value[c][i][2].

When not present in the film grain characteristics SEI message, comp_model_value[c][i][4] shall be inferred to be equal to model_id.

comp_model_value[c][i][4] is interpreted as follows.

- If model_id is equal to 0, comp_model_value[c][i][4] indicates the vertical low cut frequency to be used to filter the DCT of a block of 16x16 random values.
- Otherwise (model_id is equal to 1), comp_model_value[c][i][4] indicates the aspect ratio of the modelled grain.

comp_model_value[c][i][5] provides the sixth model value for the model as specified by model_id. When not present in the film grain characteristics SEI message, comp_model_value[c][i][5] shall be inferred to be equal to 0.

comp_model_value[c][i][5] is interpreted as follows.

- If model_id is equal to 0, comp_model_value[c][i][5] indicates the colour correlation between consecutive colour components.
- Otherwise (model_id is equal to 1), comp_model_value[c][i][5] indicates the second order spatial correlation for neighbouring samples (x, y-2) and (x-2, y).

film_grain_characteristics_repetition_period specifies the persistence of the film grain characteristics SEI message and may specify a picture order count interval within which another film grain characteristics SEI message or the end of the coded video sequence shall be present in the bitstream. The value of film_grain_characteristics_repetition_period shall be in the range 0 to 16 384, inclusive.

film_grain_characteristics_repetition_period equal to 0 specifies that the film grain characteristics SEI message applies to the current decoded picture only.

film_grain_characteristics_repetition_period equal to 1 specifies that the film grain characteristics SEI message persists in output order until any of the following conditions are true.

- A new coded video sequence begins, or
- A picture in an access unit containing a film grain characteristics SEI message that is output having PicOrderCnt() greater than PicOrderCnt(CurrPic).

film_grain_characteristics_repetition_period greater than 1 specifies that the film grain characteristics SEI message persists until any of the following conditions are true.

- A new coded video sequence begins, or
- A picture in an access unit containing a film grain characteristics SEI message is output having PicOrderCnt() greater than PicOrderCnt(CurrPic) and less than or equal to PicOrderCnt(CurrPic) + film_grain_characteristics_repetition_period.

film_grain_characteristics_repetition_period greater than 1 indicates that another film grain characteristics SEI message shall be present for a picture in an access unit that is output having PicOrderCnt() greater than PicOrderCnt(CurrPic) and less than or equal to PicOrderCnt(CurrPic) + film_grain_characteristics_repetition_period; unless the bitstream ends or a new coded video sequence begins without output of such a picture.

D.2.21 Deblocking filter display preference SEI message semantics

This SEI message provides the decoder with an indication of whether the display of the cropped result of the deblocking filter process specified in subclause 8.7 or of the cropped result of the picture construction process prior to the deblocking filter process specified in subclause 8.5.12 is preferred by the encoder for the display of each decoded picture that is output.

NOTE 1 – The display process is not specified in this Recommendation | International Standard. The means by which an encoder determines what to indicate as its preference expressed in a deblocking filter display preference SEI message is also not specified in this Recommendation | International Standard, and the expression of an expressed preference in a deblocking filter display preference SEI message does not impose any requirement on the display process.

deblocking_display_preference_cancel_flag equal to 1 indicates that the SEI message cancels the persistence of any previous deblocking filter display preference SEI message in output order. **deblocking_display_preference_cancel_flag** equal to 0 indicates that a **display_prior_to_deblocking_preferred_flag** and **deblocking_display_preference_repetition_period** follow.

NOTE 2 – In the absence of the deblocking filter display preference SEI message, or after the receipt of a deblocking filter display preference SEI message in which **deblocking_display_preference_cancel_flag** is equal to 1, the decoder should infer that the display of the cropped result of the deblocking filter process specified in subclause 8.7 is preferred over the display of the cropped result of the picture construction process prior to the deblocking filter process specified in subclause 8.5.12 for the display of each decoded picture that is output.

display_prior_to_deblocking_preferred_flag equal to 1 indicates that the encoder preference is for the display process (which is not specified in this Recommendation | International Standard) to display the cropped result of the picture construction process prior to the deblocking filter process specified in subclause 8.5.12 rather than the cropped result of the deblocking filter process specified in subclause 8.7 for each picture that is cropped and output as specified in Annex C. **display_prior_to_deblocking_preferred_flag** equal to 0 indicates that the encoder preference is for the display process (which is not specified in this Recommendation | International Standard) to display the cropped result of the deblocking filter process specified in subclause 8.7 rather than the cropped result of the picture construction process prior to the deblocking filter process specified in subclause 8.5.12 for each picture that is cropped and output as specified in Annex C.

NOTE 3 – The presence or absence of the deblocking filter display preference SEI message and the value of **display_prior_to_deblocking_preferred_flag** does not affect the requirements of the decoding process specified in this Recommendation | International Standard. Rather, it only provides an indication of when, in addition to fulfilling the requirements of this Recommendation | International Standard for the decoding process, enhanced visual quality might be obtained by performing the display process (which is not specified in this Recommendation | International Standard) in an alternative fashion. Encoders that use the deblocking filter display preference SEI message should be designed with an awareness that unless the encoder restricts its use of the DPB capacity specified in Annex A for the profile and level in use, some decoders may not have sufficient memory capacity for the storage of the result of the picture construction process prior to the deblocking filter process specified in subclause 8.5.12 in addition to the storage of the result of the deblocking filter process specified in subclause 8.7 when reordering and delaying pictures for display, and such decoders would therefore not be able to benefit from the preference indication. By restricting its use of the DPB capacity, an encoder can be able to use at least half of the DPB capacity specified in Annex A while allowing the decoder to use the remaining capacity for storage of unfiltered pictures that have been indicated as preferable for display until the output time arrives for those pictures.

dec_frame_buffering_constraint_flag equal to 1 indicates that the use of the frame buffering capacity of the HRD decoded picture buffer (DPB) as specified by **max_dec_frame_buffering** has been constrained such that the coded video sequence will not require a decoded picture buffer with more than $\text{Max}(1, \text{max_dec_frame_buffering})$ frame buffers to enable the output of the decoded filtered or unfiltered pictures, as indicated by the deblocking filter display preference SEI messages, at the output times specified by the **dpb_output_delay** of the picture timing SEI messages.

dec_frame_buffering_constraint_flag equal to 0 indicates that the use of the frame buffering capacity in the HRD may or may not be constrained in the manner that would be indicated by **dec_frame_buffering_constraint_flag** equal to 1.

For purposes of determining the constraint imposed when **dec_frame_buffering_constraint_flag** is equal to 1, the quantity of frame buffering capacity used at any given point in time by each frame buffer of the DPB that contains a picture shall be derived as follows:

- If both of the following criteria are satisfied for the frame buffer, the frame buffer is considered to use two frame buffers of capacity for its storage.
 - The frame buffer contains a frame or one or more fields that is marked as "used for reference", and
 - The frame buffer contains a picture for which both of the following criteria are fulfilled.
 - The HRD output time of the picture is greater than the given point in time, and
 - It has been indicated in a deblocking filter display preference SEI message that the encoder preference for the picture is for the display process to display the cropped result of the picture construction process prior to the deblocking filter process specified in subclause 8.5.12 rather than the cropped result of the deblocking filter process specified in subclause 8.7, and
- Otherwise, the frame buffer is considered to use one frame buffer of DPB capacity for its storage.

When **dec_frame_buffering_constraint_flag** is equal to 1, the frame buffering capacity used by all of the frame buffers in the DPB that contain pictures, as derived in this manner, shall not be greater than $\text{Max}(1, \text{max_dec_frame_buffering})$ during the operation of the HRD for the coded video sequence.

The value of **dec_frame_buffering_constraint_flag** shall be the same in all deblocking filter display preference SEI messages of the coded video sequence.

deblocking_display_preference_repetition_period specifies the persistence of the film grain characteristics SEI message and may specify a picture order count interval within which another film grain characteristics SEI message or the end of the coded video sequence shall be present in the bitstream. The value of **deblocking_display_preference_repetition_period** shall be in the range 0 to 16 384, inclusive.

deblocking_display_preference_repetition_period equal to 0 specifies that the deblocking filter display preference SEI message applies to the current decoded picture only.

deblocking_display_preference_repetition_period equal to 1 specifies that the deblocking filter display preference SEI message persists in output order until any of the following conditions are true.

- A new coded video sequence begins
- A picture in an access unit containing a deblocking filter display preference SEI message that is output having $\text{PicOrderCnt}()$ greater than $\text{PicOrderCnt}(\text{CurrPic})$.

deblocking_display_preference_repetition_period greater than 1 specifies that the deblocking filter display preference SEI message persists until any of the following conditions are true.

- A new coded video sequence begins
- A picture in an access unit containing a deblocking filter display preference SEI message is output having $\text{PicOrderCnt}()$ greater than $\text{PicOrderCnt}(\text{CurrPic})$ and less than or equal to $\text{PicOrderCnt}(\text{CurrPic}) + \text{deblocking_display_preference_repetition_period}$.

deblocking_display_preference_repetition_period greater than 1 indicates that another deblocking filter display preference SEI message shall be present for a picture in an access unit that is output having $\text{PicOrderCnt}()$ greater than $\text{PicOrderCnt}(\text{CurrPic})$ and less than or equal to $\text{PicOrderCnt}(\text{CurrPic}) + \text{deblocking_display_preference_repetition_period}$; unless the bitstream ends or a new coded video sequence begins without output of such a picture.

D.2.22 Stereo video information SEI message semantics

This SEI message provides the decoder with an indication that the entire coded video sequence consists of pairs of pictures forming stereo-view content.

The stereo video information SEI message shall not be present in any access unit of a coded video sequence unless a stereo video information SEI message is present in the first access unit of the coded video sequence.

field_views_flag equal to 1 indicates that all pictures in the current coded video sequence are fields and all fields of a particular parity are considered a left view and all fields of the opposite parity are considered a right view for stereo-view content. **field_views_flag** equal to 0 indicates that all pictures in the current coded video sequence are frames and alternating frames in output order represent a view of a stereo view. The value of **field_views_flag** shall be the same in all stereo video information SEI messages within a coded video sequence.

When the stereo video information SEI message is present and **field_views_flag** is equal to 1, the left view and right view of a stereo video pair shall be coded as a complementary field pair, the display time of the first field of the field pair in output order should be delayed to coincide with the display time of the second field of the field pair in output order, and the spatial locations of the samples in each individual field should be interpreted for display purposes as representing complete pictures as shown in Figure 6-1 rather than as spatially-distinct fields within a frame as shown in Figure 6-2.

NOTE – The display process is not specified in this Recommendation | International Standard.

top_field_is_left_view_flag equal to 1 indicates that the top fields in the coded video sequence represent a left view and the bottom fields in the coded video sequence represent a right view. **top_field_is_left_view_flag** equal to 0 indicates that the bottom fields in the coded video sequence represent a left view and the top fields in the coded video sequence represent a right view. When present, the value of **top_field_is_left_view_flag** shall be the same in all stereo video information SEI messages within a coded video sequence.

current_frame_is_left_view_flag equal to 1 indicates that the current picture is the left view of a stereo-view pair. **current_frame_is_left_view_flag** equal to 0 indicates that the current picture is the right view of a stereo-view pair.

next_frame_is_second_view_flag equal to 1 indicates that the current picture and the next picture in output order form a stereo-view pair, and the display time of the current picture should be delayed to coincide with the display time of the next picture in output order. **next_frame_is_second_view_flag** equal to 0 indicates that the current picture and the previous picture in output order form a stereo-view pair, and the display time of the current picture should not be delayed for purposes of stereo-view pairing.

left_view_self_contained_flag equal to 1 indicates that no inter prediction operations within the decoding process for the left-view pictures of the coded video sequence refer to reference pictures that are right-view pictures. **left_view_self_contained_flag** equal to 0 indicates that some inter prediction operations within the decoding process for the left-view pictures of the coded video sequence may or may not refer to reference pictures that are right-view pictures. Within a coded video sequence, the value of **left_view_self_contained_flag** in all stereo video information SEI messages shall be the same.

right_view_self_contained_flag equal to 1 indicates that no inter prediction operations within the decoding process for the right-view pictures of the coded video sequence refer to reference pictures that are left-view pictures. **right_view_self_contained_flag** equal to 0 indicates that some inter prediction operations within the decoding process for the right-view pictures of the coded video sequence may or may not refer to reference pictures that are left-view pictures. Within a coded video sequence, the value of **right_view_self_contained_flag** in all stereo video information SEI messages shall be the same.

D.2.23 Reserved SEI message semantics

This message consists of data reserved for future backward-compatible use by ITU-T | ISO/IEC. Encoders conforming to this Recommendation | International Standard shall not send reserved SEI messages until and unless the use of such messages has been specified by ITU-T | ISO/IEC. Decoders conforming to this Recommendation | International Standard that encounter reserved SEI messages shall discard their content without effect on the decoding process, except as specified in future Recommendations | International Standards specified by ITU-T | ISO/IEC.

reserved_sei_message_payload_byte is a byte reserved for future use by ITU-T | ISO/IEC.

Annex E

Video usability information

(This annex forms an integral part of this Recommendation | International Standard)

This Annex specifies syntax and semantics of the VUI parameters of the sequence parameter sets.

VUI parameters are not required for constructing the luma or chroma samples by the decoding process. Conforming decoders are not required to process this information for output order conformance to this Recommendation | International Standard (see Annex C for the specification of conformance). Some VUI parameters are required to check bitstream conformance and for output timing decoder conformance.

In Annex E, specification for presence of VUI parameters is also satisfied when those parameters (or some subset of them) are conveyed to decoders (or to the HRD) by other means not specified by this Recommendation | International Standard. When present in the bitstream, VUI parameters shall follow the syntax and semantics specified in subclauses 7.3.2.1 and 7.4.2.1 and this annex. When the content of VUI parameters is conveyed for the application by some means other than presence within the bitstream, the representation of the content of the VUI parameters is not required to use the same syntax specified in this annex. For the purpose of counting bits, only the appropriate bits that are actually present in the bitstream are counted.

E.2 VUI semantics

E.2.1 VUI parameters semantics

aspect_ratio_info_present_flag equal to 1 specifies that **aspect_ratio_idc** is present. **aspect_ratio_info_present_flag** equal to 0 specifies that **aspect_ratio_idc** is not present.

aspect_ratio_idc specifies the value of the sample aspect ratio of the luma samples. Table E-1 shows the meaning of the code. When **aspect_ratio_idc** indicates Extended_SAR, the sample aspect ratio is represented by **sar_width** and **sar_height**. When the **aspect_ratio_idc** syntax element is not present, **aspect_ratio_idc** value shall be inferred to be equal to 0.

Table E-1 – Meaning of sample aspect ratio indicator

aspect_ratio_idc	Sample aspect ratio	(informative) Examples of use
0	Unspecified	
1	1:1 ("square")	1280x720 16:9 frame without horizontal overscan 1920x1080 16:9 frame without horizontal overscan (cropped from 1920x1088) 640x480 4:3 frame without horizontal overscan
2	12:11	720x576 4:3 frame with horizontal overscan 352x288 4:3 frame without horizontal overscan
3	10:11	720x480 4:3 frame with horizontal overscan 352x240 4:3 frame without horizontal overscan
4	16:11	720x576 16:9 frame with horizontal overscan 528x576 4:3 frame without horizontal overscan
5	40:33	720x480 16:9 frame with horizontal overscan 528x480 4:3 frame without horizontal overscan
6	24:11	352x576 4:3 frame without horizontal overscan 480x576 16:9 frame with horizontal overscan
7	20:11	352x480 4:3 frame without horizontal overscan 480x480 16:9 frame with horizontal overscan
8	32:11	352x576 16:9 frame without horizontal overscan
9	80:33	352x480 16:9 frame without horizontal overscan
10	18:11	480x576 4:3 frame with horizontal overscan
11	15:11	480x480 4:3 frame with horizontal overscan
12	64:33	528x576 16:9 frame without horizontal overscan
13	160:99	528x480 16:9 frame without horizontal overscan
14	4:3	1440x1080 16:9 frame without horizontal overscan
15	3:2	1280x1080 16:9 frame without horizontal overscan
16	2:1	960x1080 16:9 frame without horizontal overscan
17..254	Reserved	
255	Extended_SAR	

sar_width indicates the horizontal size of the sample aspect ratio (in arbitrary units).

sar_height indicates the vertical size of the sample aspect ratio (in the same arbitrary units as sar_width).

sar_width and sar_height shall be relatively prime or equal to 0. When aspect_ratio_idc is equal to 0 or sar_width is equal to 0 or sar_height is equal to 0, the sample aspect ratio shall be considered unspecified by this Recommendation | International Standard.

overscan_info_present_flag equal to 1 specifies that the overscan_appropriate_flag is present. When overscan_info_present_flag is equal to 0 or is not present, the preferred display method for the video signal is unspecified.

overscan_appropriate_flag equal to 1 indicates that the cropped decoded pictures output are suitable for display using overscan. overscan_appropriate_flag equal to 0 indicates that the cropped decoded pictures output contain visually important information in the entire region out to the edges of the cropping rectangle of the picture, such that the cropped decoded pictures output should not be displayed using overscan. Instead, they should be displayed using either an exact match between the display area and the cropping rectangle, or using underscan.

NOTE 1 – For example, overscan_appropriate_flag equal to 1 might be used for entertainment television programming, or for a live view of people in a videoconference, and overscan_appropriate_flag equal to 0 might be used for computer screen capture or security camera content.

video_signal_type_present_flag equal to 1 specifies that video_format, video_full_range_flag and colour_description_present_flag are present. video_signal_type_present_flag equal to 0, specify that video_format, video_full_range_flag and colour_description_present_flag are not present.

video_format indicates the representation of the pictures as specified in Table E-2, before being coded in accordance with this Recommendation | International Standard. When the video_format syntax element is not present, video_format value shall be inferred to be equal to 5.

Table E-2 – Meaning of video_format

video_format	Meaning
0	Component
1	PAL
2	NTSC
3	SECAM
4	MAC
5	Unspecified video format
6	Reserved
7	Reserved

video_full_range_flag indicates the black level and range of the luma and chroma signals as derived from E'_Y , E'_{PB} , and E'_{PR} or E'_R , E'_G , and E'_B analogue component signals.

When the video_full_range_flag syntax element is not present, the value of video_full_range_flag shall be inferred to be equal to 0.

colour_description_present_flag equal to 1 specifies that colour_primaries, transfer_characteristics and matrix_coefficients are present. colour_description_present_flag equal to 0 specifies that colour_primaries, transfer_characteristics and matrix_coefficients are not present.

colour_primaries indicates the chromaticity coordinates of the source primaries as specified in Table E-3 in terms of the CIE 1931 definition of x and y as specified by ISO/CIE 10527.

When the colour_primaries syntax element is not present, the value of colour_primaries shall be inferred to be equal to 2 (the chromaticity is unspecified or is determined by the application).

Table E-3 – Colour primaries

Value	Primaries			Informative Remark
0	Reserved			For future use by ITU-T / ISO/IEC
1	primary	x	y	ITU-R Recommendation BT.709-5
	green	0.300	0.600

9-255	Reserved			For future use by ITU-T / ISO/IEC

transfer_characteristics indicates the opto-electronic transfer characteristic of the source picture as specified in Table E-4 as a function of a linear optical intensity input L_c with an analogue range of 0 to 1.

When the transfer_characteristics syntax element is not present, the value of transfer_characteristics shall be inferred to be equal to 2 (the transfer characteristics are unspecified or are determined by the application).

Table E-4 – Transfer characteristics

Value	Transfer Characteristic	Informative Remark
0	Reserved	For future use by ITU-T / ISO/IEC
1	$V = 1.099 L_c^{0.45} - 0.099$ for $1 \geq L_c \geq 0.018$ $V = 4.500 L_c$ for $0.018 > L_c \geq 0$	ITU-R Recommendation BT.709-5
2	Unspecified	Image characteristics are unknown or are determined by the application.
3	Reserved	For future use by ITU-T / ISO/IEC
4	Assumed display gamma 2.2	ITU-R Recommendation BT.470-6 System M
5	Assumed display gamma 2.8	ITU-R Recommendation BT.470-6 System B, G
6	$V = 1.099 L_c^{0.45} - 0.099$ for $1 \geq L_c \geq 0.018$ $V = 4.500 L_c$ for $0.018 > L_c \geq 0$	Society of Motion Picture and Television Engineers 170M (1999)
7	$V = 1.1115 L_c^{0.45} - 0.1115$ for $1 \geq L_c \geq 0.0228$ $V = 4.0 L_c$ for $0.0228 > L_c \geq 0$	Society of Motion Picture and Television Engineers 240M (1999)
8	$V = L_c$ for $1 > L_c \geq 0$	Linear transfer characteristics
9	$V = 1.0 - \text{Log}_{10}(L_c) \div 2$ for $1 \geq L_c \geq 0.01$ $V = 0.0$ for $0.01 > L_c \geq 0$	Logarithmic transfer characteristic (100:1 range)
10	$V = 1.0 - \text{Log}_{10}(L_c) \div 2.5$ for $1 \geq L_c \geq 0.0031622777$ $V = 0.0$ for $0.0031622777 > L_c \geq 0$	Logarithmic transfer characteristic (316.22777:1 range)
11..255	Reserved	For future use by ITU-T / ISO/IEC

matrix_coefficients describes the matrix coefficients used in deriving luma and chroma signals from the green, blue, and red primaries, as specified in Table E-5.

matrix_coefficients shall not be equal to 0 unless both of the following conditions are true

- BitDepth_C is equal to BitDepth_Y
- chroma_format_idc is equal to 3 (4:4:4)

The specification of the use of matrix_coefficients equal to 0 under all other conditions is reserved for future use by ITU-T | ISO/IEC.

matrix_coefficients shall not be equal to 8 unless one or both of the following conditions are true

- BitDepth_C is equal to BitDepth_Y
- BitDepth_C is equal to BitDepth_Y + 1 and chroma_format_idc is equal to 3 (4:4:4)

The specification of the use of matrix_coefficients equal to 8 under all other conditions is reserved for future use by ITU-T | ISO/IEC.

When the matrix_coefficients syntax element is not present, the value of matrix_coefficients shall be inferred to be equal to 2.

The interpretation of matrix_coefficients is defined as follows.

- E'_R, E'_G, and E'_B are analogue with values in the range of 0 to 1.
- White is specified as having E'_R equal to 1, E'_G equal to 1, and E'_B equal to 1.
- Black is specified as having E'_R equal to 0, E'_G equal to 0, and E'_B equal to 0.
- If video_full_range_flag is equal to 0, the following equations apply.
 - If matrix_coefficients is equal to 1, 4, 5, 6, or 7, the following equations apply.

$$Y = \text{Round}((1 \ll (\text{BitDepth}_Y - 8)) * (219 * E'_Y + 16)) \quad (\text{E-1})$$

$$Cb = \text{Round}((1 \ll (\text{BitDepth}_C - 8)) * (224 * E'_{PB} + 128)) \quad (\text{E-2})$$

$$Cr = \text{Round}((1 \ll (\text{BitDepth}_C - 8)) * (224 * E'_{PR} + 128)) \quad (\text{E-3})$$

- Otherwise, if matrix_coefficients is equal to 0 or 8, the following equations apply.

$$R = (1 \ll (\text{BitDepth}_Y - 8)) * (219 * E'_R + 16) \quad (\text{E-4})$$

$$G = (1 \ll (\text{BitDepth}_Y - 8)) * (219 * E'_G + 16) \quad (\text{E-5})$$

$$B = (1 \ll (\text{BitDepth}_Y - 8)) * (219 * E'_B + 16) \quad (\text{E-6})$$

- Otherwise, if matrix_coefficients is equal to 2, the interpretation of the matrix_coefficients syntax element is unknown or is determined by the application.
- Otherwise (matrix_coefficients is not equal to 0, 1, 2, 4, 5, 6, 7, or 8), the interpretation of the matrix_coefficients syntax element is reserved for future definition by ITU-T | ISO/IEC.
- Otherwise (video_full_range_flag is equal to 1), the following equations apply.
 - If matrix_coefficients is equal to 1, 4, 5, 6, or 7, the following equations apply.

$$Y = \text{Round}((1 \ll \text{BitDepth}_Y) - 1) * E'_Y \quad (\text{E-7})$$

$$Cb = \text{Round}(((1 \ll \text{BitDepth}_C) - 1) * E'_{PB} + (1 \ll (\text{BitDepth}_C - 1))) \quad (\text{E-8})$$

$$Cr = \text{Round}(((1 \ll \text{BitDepth}_C) - 1) * E'_{PR} + (1 \ll (\text{BitDepth}_C - 1))) \quad (\text{E-9})$$

- Otherwise, if matrix_coefficients is equal to 0 or 8, the following equations apply.

$$R = ((1 \ll \text{BitDepth}_Y) - 1) * E'_R \quad (\text{E-10})$$

$$G = ((1 \ll \text{BitDepth}_Y) - 1) * E'_G \quad (\text{E-11})$$

$$B = ((1 \ll \text{BitDepth}_Y) - 1) * E'_B \quad (\text{E-12})$$

- Otherwise, if matrix_coefficients is equal to 2, the interpretation of the matrix_coefficients syntax element is unknown or is determined by the application.
- Otherwise (matrix_coefficients is not equal to 0, 1, 2, 4, 5, 6, 7, or 8), the interpretation of the matrix_coefficients syntax element is reserved for future definition by ITU-T | ISO/IEC.
- If matrix_coefficients is not equal to 0 or 8, the following equations apply.

$$E'_Y = K_R * E'_R + (1 - K_R - K_B) * E'_G + K_B * E'_B \quad (\text{E-13})$$

$$E'_{PB} = 0.5 * (E'_B - E'_Y) \div (1 - K_B) \quad (\text{E-14})$$

$$E'_{PR} = 0.5 * (E'_R - E'_Y) \div (1 - K_R) \quad (\text{E-15})$$

NOTE 2 – Then E'_Y is analogue with values in the range of 0 to 1, E'_{PB} and E'_{PR} are analogue with values in the range of -0.5 to 0.5, and white is equivalently given by $E'_Y = 1$, $E'_{PB} = 0$, $E'_{PR} = 0$.

- Otherwise, if matrix_coefficients is equal to 0, the following equations apply.

$$Y = \text{Round}(G) \quad (\text{E-16})$$

$$Cb = \text{Round}(B) \quad (\text{E-17})$$

$$Cr = \text{Round}(R) \quad (\text{E-18})$$

- Otherwise (matrix_coefficients is equal to 8), the following applies.
 - If BitDepth_C is equal to BitDepth_Y, the following equations apply.

$$Y = \text{Round}(0.5 * G + 0.25 * (R + B)) \quad (\text{E-19})$$

$$Cb = \text{Round}(0.5 * G - 0.25 * (R + B)) \quad (\text{E-20})$$

$$Cr = \text{Round}(0.5 * (R - B)) \quad (\text{E-21})$$

NOTE 3 – For purposes of the YCgCo nomenclature used in Table E-5, Cb and Cr of Equations E-20 and E-21 may be referred to as Cg and Co, respectively. The inverse conversion for the above four equations should be computed as.

$$t = Y - Cb \quad (\text{E-22})$$

$$G = Y + Cb \quad (\text{E-23})$$

$$B = t - Cr \quad (\text{E-24})$$

$$R = t + Cr \quad (\text{E-25})$$

- Otherwise (BitDepth_C is not equal to BitDepth_Y), the following equations apply.

$$Cr = \text{Round}(R) - \text{Round}(B) \quad (\text{E-26})$$

$$t = \text{Round}(B) + (Cr \gg 1) \quad (\text{E-27})$$

$$Cb = \text{Round}(G) - t \quad (\text{E-28})$$

$$Y = t + (Cb \gg 1) \quad (\text{E-29})$$

NOTE 4 – For purposes of the YCgCo nomenclature used in Table E-5, Cb and Cr of Equations E-28 and E-26 may be referred to as Cg and Co, respectively. The inverse conversion for the above four equations should be computed as.

$$t = Y - (Cb \gg 1) \quad (\text{E-30})$$

$$G = t + Cb \quad (\text{E-31})$$

$$B = t - (Cr \gg 1) \quad (\text{E-32})$$

$$R = B + Cr \quad (\text{E-33})$$

Table E-5 – Matrix coefficients

Value	Matrix	Informative remark
0	GBR	Typically referred to as RGB; see Equations E-16 to E-18
1	$K_R = 0.2126$; $K_B = 0.0722$	ITU-R Recommendation BT.709-5 and Society of Motion Picture and Television Engineers RP177 (1993)
2	Unspecified	Image characteristics are unknown or are determined by the application.
3	Reserved	For future use by ITU-T / ISO/IEC
4	$K_R = 0.30$; $K_B = 0.11$	United States Federal Communications Commission Title 47 Code of Federal Regulations (2003) 73.682 (a) (20)
5	$K_R = 0.299$; $K_B = 0.114$	ITU-R Recommendation BT.470-6 System B, G
6	$K_R = 0.299$; $K_B = 0.114$	Society of Motion Picture and Television Engineers 170M (1999)
7	$K_R = 0.212$; $K_B = 0.087$	Society of Motion Picture and Television Engineers 240M (1999)
8	YCgCo	See Equations E-19 to E-33
9-255	Reserved	For future use by ITU-T / ISO/IEC

chroma_loc_info_present_flag equal to 1 specifies that **chroma_sample_loc_type_top_field** and **chroma_sample_loc_type_bottom_field** are present. **chroma_loc_info_present_flag** equal to 0 specifies that **chroma_sample_loc_type_top_field** and **chroma_sample_loc_type_bottom_field** are not present.

chroma_sample_loc_type_top_field and **chroma_sample_loc_type_bottom_field** specify the location of chroma samples for the top field and the bottom field as shown in Figure E-1. The value of **chroma_sample_loc_type_top_field** and **chroma_sample_loc_type_bottom_field** shall be in the range of 0 to 5, inclusive. When the **chroma_sample_loc_type_top_field** and **chroma_sample_loc_type_bottom_field** are not present, the values of **chroma_sample_loc_type_top_field** and **chroma_sample_loc_type_bottom_field** shall be inferred to be equal to 0.

NOTE 5 – When coding progressive source material, **chroma_sample_loc_type_top_field** and **chroma_sample_loc_type_bottom_field** should have the same value.

For each picture n where n indicates the n -th picture (in output order) that is output and picture n is not the last picture in the bitstream (in output order) that is output, the value of $\Delta t_{fi,dpb}(n)$ is specified by

$$\Delta t_{fi,dpb}(n) = \Delta t_{o,dpb}(n) \div \text{DeltaTfiDivisor} \quad (\text{E-34})$$

where $\Delta t_{o,dpb}(n)$ is specified in Equation C-13 and DeltaTfiDivisor is specified by Table E-6 based on the value of pic_struct_present_flag, field_pic_flag, and pic_struct for the coded video sequence containing picture n . Entries marked "-" in Table E-6 indicate a lack of dependence of DeltaTfiDivisor on the corresponding syntax element.

When fixed_frame_rate_flag is equal to 1 for a coded video sequence containing picture n , the value computed for $\Delta t_{fi,dpb}(n)$ shall be equal to t_c as specified in Equation C-1 (using the value of t_c for the coded video sequence containing picture n) when either or both of the following conditions are true for the following picture n_n that is specified for use in Equation C-13.

- picture n_n is in the same coded video sequence as picture n .
- picture n_n is in a different coded video sequence and fixed_frame_rate_flag is equal to 1 in the coded video sequence containing picture n_n and the value of num_units_in_tick \div time_scale is the same for both coded video sequences.

Table E-6 – Divisor for computation of $\Delta t_{fi,dpb}(n)$

pic_struct_present_flag	field_pic_flag	pic_struct	DeltaTfiDivisor
0	1	-	1
1	-	1	1
1	-	2	1
0	0	-	2
1	-	0	2
1	-	3	2
1	-	4	2
1	-	5	3
1	-	6	3
1	-	7	4
1	-	8	6

nal_hrd_parameters_present_flag equal to 1 specifies that NAL HRD parameters (pertaining to Type II bitstream conformance) are present. nal_hrd_parameters_present_flag equal to 0 specifies that NAL HRD parameters are not present.

NOTE 6 – When nal_hrd_parameters_present_flag is equal to 0, the conformance of the bitstream cannot be verified without provision of the NAL HRD parameters, including the NAL sequence HRD parameter information and all buffering period and picture timing SEI messages, by some means not specified in this Recommendation | International Standard.

When nal_hrd_parameters_present_flag is equal to 1, NAL HRD parameters (subclauses E.1.2 and E.2.2) immediately follow the flag.

The variable NalHrdBpPresentFlag is derived as follows.

- If any of the following is true, the value of NalHrdBpPresentFlag shall be set equal to 1.
 - nal_hrd_parameters_present_flag is present in the bitstream and is equal to 1
 - the need for presence of buffering periods for NAL HRD operation to be present in the bitstream in buffering period SEI messages is determined by the application, by some means not specified in this Recommendation | International Standard.
- Otherwise, the value of NalHrdBpPresentFlag shall be set equal to 0.

vcl_hrd_parameters_present_flag equal to 1 specifies that VCL HRD parameters (pertaining to all bitstream conformance) are present. vcl_hrd_parameters_present_flag equal to 0 specifies that VCL HRD parameters are not present.

NOTE 7 – When vcl_hrd_parameters_present_flag is equal to 0, the conformance of the bitstream cannot be verified without provision of the VCL HRD parameters and all buffering period and picture timing SEI messages, by some means not specified in this Recommendation | International Standard.

When `vcl_hrd_parameters_present_flag` is equal to 1, VCL HRD parameters (subclauses E.1.2 and E.2.2) immediately follow the flag.

The variable `VclHrdBpPresentFlag` is derived as follows.

- If any of the following is true, the value of `VclHrdBpPresentFlag` shall be set equal to 1.
 - `vcl_hrd_parameters_present_flag` is present in the bitstream and is equal to 1
 - the need for presence of buffering periods for VCL HRD operation to be present in the bitstream in buffering period SEI messages is determined by the application, by some means not specified in this Recommendation | International Standard.
- Otherwise, the value of `VclHrdBpPresentFlag` shall be set equal to 0.

The variable `CpbDpbDelaysPresentFlag` is derived as follows.

- If any of the following is true, the value of `CpbDpbDelaysPresentFlag` shall be set equal to 1.
 - `nal_hrd_parameters_present_flag` is present in the bitstream and is equal to 1
 - `vcl_hrd_parameters_present_flag` is present in the bitstream and is equal to 1
 - the need for presence of CPB and DPB output delays to be present in the bitstream in picture timing SEI messages is determined by the application, by some means not specified in this Recommendation | International Standard.
- Otherwise, the value of `CpbDpbDelaysPresentFlag` shall be set equal to 0.

low_delay_hrd_flag specifies the HRD operational mode as specified in Annex C. When `fixed_frame_rate_flag` is equal to 1, `low_delay_hrd_flag` shall be equal to 0.

NOTE 8 – When `low_delay_hrd_flag` is equal to 1, "big pictures" that violate the nominal CPB removal times due to the number of bits used by an access unit are permitted. It is expected, but not required, that such "big pictures" occur only occasionally.

pic_struct_present_flag equal to 1 specifies that picture timing SEI messages (subclause D.2.2) are present that include the `pic_struct` syntax element. `pic_struct_present_flag` equal to 0 specifies that the `pic_struct` syntax element is not present in picture timing SEI messages. When `pic_struct_present_flag` is not present, its value shall be inferred to be equal to 0.

bitstream_restriction_flag equal to 1, specifies that the following coded video sequence bitstream restriction parameters are present. `bitstream_restriction_flag` equal to 0, specifies that the following coded video sequence bitstream restriction parameters are not present.

motion_vectors_over_pic_boundaries_flag equal to 0 indicates that no sample outside the picture boundaries and no sample at a fractional sample position whose value is derived using one or more samples outside the picture boundaries is used to inter predict any sample. `motion_vectors_over_pic_boundaries_flag` equal to 1 indicates that one or more samples outside picture boundaries may be used in inter prediction. When the `motion_vectors_over_pic_boundaries_flag` syntax element is not present, `motion_vectors_over_pic_boundaries_flag` value shall be inferred to be equal to 1.

max_bytes_per_pic_denom indicates a number of bytes not exceeded by the sum of the sizes of the VCL NAL units associated with any coded picture in the coded video sequence.

The number of bytes that represent a picture in the NAL unit stream is specified for this purpose as the total number of bytes of VCL NAL unit data (i.e., the total of the `NumBytesInNALunit` variables for the VCL NAL units) for the picture. The value of `max_bytes_per_pic_denom` shall be in the range of 0 to 16, inclusive.

Depending on `max_bytes_per_pic_denom` the following applies.

- If `max_bytes_per_pic_denom` is equal to 0, no limits are indicated.
- Otherwise (`max_bytes_per_pic_denom` is not equal to 0), no coded picture shall be represented in the coded video sequence by more than the following number of bytes.

$$(\text{PicSizeInMbs} * \text{RawMbBits}) \div (8 * \text{max_bytes_per_pic_denom}) \quad (\text{E-35})$$

When the `max_bytes_per_pic_denom` syntax element is not present, the value of `max_bytes_per_pic_denom` shall be inferred to be equal to 2.

max_bits_per_mb_denom indicates the maximum number of coded bits of `macroblock_layer()` data for any macroblock in any picture of the coded video sequence. The value of `max_bits_per_mb_denom` shall be in the range of 0 to 16, inclusive.

Depending on `max_bits_per_mb_denom` the following applies.

- If `max_bits_per_mb_denom` is equal to 0, no limit is specified.
- Otherwise (`max_bits_per_mb_denom` is not equal to 0), no coded `macroblock_layer()` shall be represented in the bitstream by more than the following number of bits.

$$(128 + \text{RawMbBits}) \div \text{max_bits_per_mb_denom} \quad (\text{E-36})$$

Depending on `entropy_coding_mode_flag`, the bits of `macroblock_layer()` data are counted as follows.

- If `entropy_coding_mode_flag` is equal to 0, the number of bits of `macroblock_layer()` data is given by the number of bits in the `macroblock_layer()` syntax structure for a macroblock.
- Otherwise (`entropy_coding_mode_flag` is equal to 1), the number of bits of `macroblock_layer()` data for a macroblock is given by the number of times `read_bits(1)` is called in subclauses 9.3.3.2.2 and 9.3.3.2.3 when parsing the `macroblock_layer()` associated with the macroblock.

When the `max_bits_per_mb_denom` is not present, the value of `max_bits_per_mb_denom` shall be inferred to be equal to 1.

`log2_max_mv_length_horizontal` and **`log2_max_mv_length_vertical`** indicate the maximum absolute value of a decoded horizontal and vertical motion vector component, respectively, in $\frac{1}{4}$ luma sample units, for all pictures in the coded video sequence. A value of n asserts that no value of a motion vector component shall exceed the range from -2^n to $2^n - 1$, inclusive, in units of $\frac{1}{4}$ luma sample displacement. The value of `log2_max_mv_length_horizontal` shall be in the range of 0 to 16, inclusive. The value of `log2_max_mv_length_vertical` shall be in the range of 0 to 16, inclusive. When `log2_max_mv_length_horizontal` is not present, the values of `log2_max_mv_length_horizontal` and `log2_max_mv_length_vertical` shall be inferred to be equal to 16.

NOTE 9 – The maximum absolute value of a decoded vertical or horizontal motion vector component is also constrained by profile and level limits as specified in Annex A.

`num_reorder_frames` indicates the maximum number of frames, complementary field pairs, or non-paired fields that precede any frame, complementary field pair, or non-paired field in the coded video sequence in decoding order and follow it in output order. The value of `num_reorder_frames` shall be in the range of 0 to `max_dec_frame_buffering`, inclusive. When the `num_reorder_frames` syntax element is not present, the value of `num_reorder_frames` value shall be inferred to be equal to `max_dec_frame_buffering`.

`max_dec_frame_buffering` specifies the required size of the HRD decoded picture buffer (DPB) in units of frame buffers. The coded video sequence shall not require a decoded picture buffer with size of more than $\text{Max}(1, \text{max_dec_frame_buffering})$ frame buffers to enable the output of decoded pictures at the output times specified by `dpb_output_delay` of the picture timing SEI messages. The value of `max_dec_frame_buffering` shall be in the range of `num_ref_frames` to `MaxDpbSize` (as specified in subclause A.3.1 or A.3.2), inclusive. When the `max_dec_frame_buffering` syntax element is not present, the value of `max_dec_frame_buffering` shall be inferred to be equal to `MaxDpbSize`.

E.2.2 HRD parameters semantics

`cpb_cnt_minus1` plus 1 specifies the number of alternative CPB specifications in the bitstream. The value of `cpb_cnt_minus1` shall be in the range of 0 to 31, inclusive. When `low_delay_hrd_flag` is equal to 1, `cpb_cnt_minus1` shall be equal to 0. When `cpb_cnt_minus1` is not present, it shall be inferred to be equal to 0.

`bit_rate_scale` (together with `bit_rate_value_minus1[SchedSelIdx]`) specifies the maximum input bit rate of the `SchedSelIdx`-th CPB.

`cpb_size_scale` (together with `cpb_size_value_minus1[SchedSelIdx]`) specifies the CPB size of the `SchedSelIdx`-th CPB.

`bit_rate_value_minus1[SchedSelIdx]` (together with `bit_rate_scale`) specifies the maximum input bit rate for the `SchedSelIdx`-th CPB. `bit_rate_value_minus1[SchedSelIdx]` shall be in the range of 0 to $2^{32} - 2$, inclusive. For any `SchedSelIdx > 0`, `bit_rate_value_minus1[SchedSelIdx]` shall be greater than `bit_rate_value_minus1[SchedSelIdx - 1]`. The bit rate in bits per second is given by

$$\text{BitRate[SchedSelIdx]} = (\text{bit_rate_value_minus1[SchedSelIdx]} + 1) * 2^{(6 + \text{bit_rate_scale})} \quad (\text{E-37})$$

When the `bit_rate_value_minus1[SchedSelIdx]` syntax element is not present, the value of `BitRate[SchedSelIdx]` shall be inferred as follows.

- If `profile_idc` is equal to 66, 77, or 88, `BitRate[SchedSelIdx]` shall be inferred to be equal to $1000 * \text{MaxBR}$ for VCL HRD parameters and to be equal to $1200 * \text{MaxBR}$ for NAL HRD parameters, where `MaxBR` is specified in subclause A.3.1.
- Otherwise, `BitRate[SchedSelIdx]` shall be inferred to be equal to `cpbBrVclFactor * MaxBR` for VCL HRD parameters and to be equal to `cpbBrNalFactor * MaxBR` for NAL HRD parameters, where `cpbBrVclFactor`, `cpbBrNalFactor`, and `MaxBR` are specified in subclause A.3.3.

`cpb_size_value_minus1[SchedSelIdx]` is used together with `cpb_size_scale` to specify the `SchedSelIdx`-th CPB size. `cpb_size_value_minus1[SchedSelIdx]` shall be in the range of 0 to $2^{32} - 2$, inclusive. For any `SchedSelIdx` greater than 0, `cpb_size_value_minus1[SchedSelIdx]` shall be less than or equal to `cpb_size_value_minus1[SchedSelIdx - 1]`.

The CPB size in bits is given by

$$\text{CpbSize[SchedSelIdx]} = (\text{cpb_size_value_minus1[SchedSelIdx]} + 1) * 2^{(4 + \text{cpb_size_scale})} \quad (\text{E-38})$$

When the `cpb_size_value_minus1[SchedSelIdx]` syntax element is not present, the value of `CpbSize[SchedSelIdx]` shall be inferred as follows.

- If `profile_idc` is equal to 66, 77, or 88, `CpbSize[SchedSelIdx]` shall be inferred to be equal to $1000 * \text{MaxCPB}$ for VCL HRD parameters and to be equal to $1200 * \text{MaxCPB}$ for NAL HRD parameters, where `MaxCPB` is specified in subclause A.3.1.
- Otherwise, `CpbSize[SchedSelIdx]` shall be inferred to be equal to `cpbBrVclFactor * MaxCPB` for VCL HRD parameters and to be equal to `cpbBrNalFactor * MaxCPB` for NAL HRD parameters, where `cpbBrVclFactor`, `cpbBrNalFactor`, and `MaxCPB` are specified in subclause A.3.3.

`cbr_flag[SchedSelIdx]` equal to 0 specifies that to decode this bitstream by the HRD using the `SchedSelIdx`-th CPB specification, the hypothetical stream delivery scheduler (HSS) operates in an intermittent bit rate mode. `cbr_flag[SchedSelIdx]` equal to 1 specifies that the HSS operates in a constant bit rate (CBR) mode. When the `cbr_flag[SchedSelIdx]` syntax element is not present, the value of `cbr_flag` shall be inferred to be equal to 0.

`initial_cpb_removal_delay_length_minus1` specifies the length in bits of the `initial_cpb_removal_delay[SchedSelIdx]` and `initial_cpb_removal_delay_offset[SchedSelIdx]` syntax elements of the buffering period SEI message. The length of `initial_cpb_removal_delay[SchedSelIdx]` and of `initial_cpb_removal_delay_offset[SchedSelIdx]` is `initial_cpb_removal_delay_length_minus1 + 1`. When the `initial_cpb_removal_delay_length_minus1` syntax element is present in more than one `hrd_parameters()` syntax structure within the VUI parameters syntax structure, the value of the `initial_cpb_removal_delay_length_minus1` parameters shall be equal in both `hrd_parameters()` syntax structures. When the `initial_cpb_removal_delay_length_minus1` syntax element is not present, it shall be inferred to be equal to 23.

`cpb_removal_delay_length_minus1` specifies the length in bits of the `cpb_removal_delay` syntax element. The length of the `cpb_removal_delay` syntax element of the picture timing SEI message is `cpb_removal_delay_length_minus1 + 1`. When the `cpb_removal_delay_length_minus1` syntax element is present in more than one `hrd_parameters()` syntax structure within the VUI parameters syntax structure, the value of the `cpb_removal_delay_length_minus1` parameters shall be equal in both `hrd_parameters()` syntax structures. When the `cpb_removal_delay_length_minus1` syntax element is not present, it shall be inferred to be equal to 23.

`dpb_output_delay_length_minus1` specifies the length in bits of the `dpb_output_delay` syntax element. The length of the `dpb_output_delay` syntax element of the picture timing SEI message is `dpb_output_delay_length_minus1 + 1`. When the `dpb_output_delay_length_minus1` syntax element is present in more than one `hrd_parameters()` syntax structure within the VUI parameters syntax structure, the value of the `dpb_output_delay_length_minus1` parameters shall be equal in both `hrd_parameters()` syntax structures. When the `dpb_output_delay_length_minus1` syntax element is not present, it shall be inferred to be equal to 23.

`time_offset_length` greater than 0 specifies the length in bits of the `time_offset` syntax element. `time_offset_length` equal to 0 specifies that the `time_offset` syntax element is not present. When the `time_offset_length` syntax element is present in more than one `hrd_parameters()` syntax structure within the VUI parameters syntax structure, the value of the `time_offset_length` parameters shall be equal in both `hrd_parameters()` syntax structures. When the `time_offset_length` syntax element is not present, it shall be inferred to be equal to 24.

SERIES OF ITU-T RECOMMENDATIONS

Series A	Organization of the work of ITU-T
Series D	General tariff principles
Series E	Overall network operation, telephone service, service operation and human factors
Series F	Non-telephone telecommunication services
Series G	Transmission systems and media, digital systems and networks

Security for mobile multimedia collaboration applications and services	H.540–H.549
VEHICULAR GATEWAYS AND INTELLIGENT TRANSPORTATION SYSTEMS (ITS)	
Architecture for vehicular gateways	H.550–H.559
Vehicular gateway interfaces	H.560–H.569
BROADBAND, TRIPLE-PLAY AND ADVANCED MULTIMEDIA SERVICES	
Broadband multimedia services over VDSL	H.610–H.619
Advanced multimedia services and applications	H.620–H.629
Content delivery and ubiquitous sensor network applications	H.640–H.649
IPTV MULTIMEDIA SERVICES AND APPLICATIONS FOR IPTV	
General aspects	H.700–H.719
IPTV terminal devices	H.720–H.729
IPTV middleware	H.730–H.739
IPTV application event handling	H.740–H.749
IPTV metadata	H.750–H.759
IPTV multimedia application frameworks	H.760–H.769
IPTV service discovery up to consumption	H.770–H.779
Digital Signage	H.780–H.789
E-HEALTH MULTIMEDIA SYSTEMS, SERVICES AND APPLICATIONS	
Personal health systems	H.810–H.819
Interoperability compliance testing of personal health systems (HRN, PAN, LAN, TAN and WAN)	H.820–H.859
Multimedia e-health data exchange services	H.860–H.869
Safe listening	H.870–H.879

For further details, please refer to the list of ITU-T Recommendations.

High efficiency video coding

Summary

Recommendation ITU-T H.265 | International Standard ISO/IEC 23008-2 represents an evolution of the existing video coding Recommendations (ITU-T H.261, ITU-T H.262, ITU-T H.263 and ITU-T H.264) and was developed in response to the growing need for higher compression of moving pictures for various applications such as Internet streaming, communication, videoconferencing, digital storage media and television broadcasting. It is also designed to enable the use of the coded video representation in a flexible manner for a wide variety of network environments. The use of this Recommendation | International Standard allows motion video to be manipulated as a form of computer data and to be stored on various storage media, transmitted and received over existing and future networks and distributed on existing and future broadcasting channels.

This revision adds an additional SEI message for shutter interval information, and also includes corrections to various minor defects in the prior content of the Specification.

This Recommendation | International Standard was developed jointly with ISO/IEC JTC 1/SC 29 and corresponds in a technically aligned manner to ISO/IEC 23008-2.

History

Edition	Recommendation	Approval	Study Group	Unique ID*
1.0	ITU-T H.265	2013-04-13	16	11.1002/1000/11885
2.0	ITU-T H.265 (V2)	2014-10-29	16	11.1002/1000/12296
3.0	ITU-T H.265 (V3)	2015-04-29	16	11.1002/1000/12455
4.0	ITU-T H.265 (V4)	2016-12-22	16	11.1002/1000/12905
5.0	ITU-T H.265 (V5)	2018-02-13	16	11.1002/1000/13433
6.0	ITU-T H.265 (V6)	2019-06-29	16	11.1002/1000/13904
7.0	ITU-T H.265 (V7)	2019-11-29	16	11.1002/1000/14107
8.0	ITU-T H.265 (V8)	2021-08-22	16	11.1002/1000/14660

Keywords

Compression coding, digital video, image coding, supplemental enhancement information, video coding, video compression, visual coding.

FOREWORD

The International Telecommunication Union (ITU) is the United Nations specialized agency in the field of telecommunications, information and communication technologies (ICTs). The ITU Telecommunication Standardization Sector (ITU-T) is a permanent organ of ITU. ITU-T is responsible for studying technical, operating and tariff questions and issuing Recommendations on them with a view to standardizing telecommunications on a worldwide basis.

The World Telecommunication Standardization Assembly (WTSA), which meets every four years, establishes the topics for study by the ITU-T study groups which, in turn, produce Recommendations on these topics.

The approval of ITU-T Recommendations is covered by the procedure laid down in WTSA Resolution 1.

In some areas of information technology which fall within ITU-T's purview, the necessary standards are prepared on a collaborative basis with ISO and IEC.

NOTE

In this Recommendation, the expression "Administration" is used for conciseness to indicate both a telecommunication administration and a recognized operating agency.

Compliance with this Recommendation is voluntary. However, the Recommendation may contain certain mandatory provisions (to ensure, e.g., interoperability or applicability) and compliance with the Recommendation is achieved when all of these mandatory provisions are met. The words "shall" or some other obligatory language such as "must" and the negative equivalents are used to express requirements. The use of such words does not suggest that compliance with the Recommendation is required of any party.

INTELLECTUAL PROPERTY RIGHTS

ITU draws attention to the possibility that the practice or implementation of this Recommendation may involve the use of a claimed Intellectual Property Right. ITU takes no position concerning the evidence, validity or applicability of claimed Intellectual Property Rights, whether asserted by ITU members or others outside of the Recommendation development process.

As of the date of approval of this Recommendation, ITU had received notice of intellectual property, protected by patents/software copyrights, which may be required to implement this Recommendation. However, implementers are cautioned that this may not represent the latest information and are therefore strongly urged to consult the appropriate ITU-T databases available via the ITU-T website at <http://www.itu.int/ITU-T/ipr/>.

Figure C.2 – HRD buffer model	277
Figure D.1 – Nominal vertical and horizontal sampling locations of 4:2:0 samples in top and bottom fields	327
Figure D.2 – Nominal vertical and horizontal sampling locations of 4:2:2 samples in top and bottom fields	327
Figure D.3 – Nominal vertical and horizontal sampling locations of 4:4:4 samples in top and bottom fields	327
Figure D.4 – Rearrangement and upconversion of side-by-side packing arrangement with frame_packing_arrangement_type equal to 3, quincunx_sampling_flag equal to 0 and (x, y) equal to (0, 0) or (4, 8) for both constituent frames.....	350

Figure D.5 – Rearrangement and upconversion of side-by-side packing arrangement with frame_packing_arrangement_type equal to 3, quincunx_sampling_flag equal to 0, (x, y) equal to (12, 8) for constituent frame 0 and (x, y) equal to (0, 0) or (4, 8) for constituent frame 1	351
Figure D.6 – Rearrangement and upconversion of top-bottom packing arrangement with frame_packing_arrangement_type equal to 4, quincunx_sampling_flag equal to 0 and (x, y) equal to (0, 0) or (8, 4) for both constituent frames.....	351
Figure D.7 – Rearrangement and upconversion of top-bottom packing arrangement with frame_packing_arrangement_type equal to 4, quincunx_sampling_flag equal to 0, (x, y) equal to (8, 12) for constituent frame 0 and (x, y) equal to (0, 0) or (8, 4) for constituent frame 1	352
Figure D.8 – Rearrangement and upconversion of side-by-side packing arrangement with quincunx sampling (frame_packing_arrangement_type equal to 3 with quincunx_sampling_flag equal to 1)	352
Figure D.9 – Rearrangement of a temporal interleaving frame arrangement (frame_packing_arrangement_type equal to 5).....	353
Figure D.10 – Rearrangement of a segmented rectangular frame packing arrangement	368
Figure D.11 – A knee function with num_knee_points_minus1 equal to 2.....	381
Figure E.1 – Location of chroma samples for top and bottom fields for chroma_format_idc equal to 1 (4:2:0 chroma format) as a function of chroma_sample_loc_type_top_field and chroma_sample_loc_type_bottom_field.....	432
Figure E.2 – Location of the top-left chroma sample when chroma_format_idc is equal to 1 (4:2:0 chroma format) as a function of ChromaLocType	433
Figure E.3 – Location of the top-left chroma sample when chroma_format_idc is equal to 1 (4:2:0 chroma format) when ChromaLocType is equal to 1	433
Figure F.1 – Bitstream-partition-specific HRD buffer model.....	518

LIST OF TABLES

Table 5-1 – Operation precedence from highest (at top of table) to lowest (at bottom of table)	19
Table 6-1 – SubWidthC and SubHeightC values derived from chroma_format_idc and separate_colour_plane_flag	22
Table 7-1 – NAL unit type codes and NAL unit type classes.....	66
Table 7-2 – Interpretation of pic_type	88
Table 7-3 – Specification of sizeId	93
Table 7-4 – Specification of matrixId according to sizeId, prediction mode and colour component	93
Table 7-5 – Specification of default values of ScalingList[0][matrixId][i] with i = 0..15	94
Table 7-6 – Specification of default values of ScalingList[1..3][matrixId][i] with i = 0..63	94
Table 7-7 – Name association to slice_type	96
Table 7-8 – Specification of the SAO type.....	105
Table 7-9 – Specification of the SAO edge offset class	106
Table 7-10 – Name association to prediction mode and partitioning type.....	108
Table 7-11 – Name association to inter prediction mode	109
Table 8-1 – Specification of intra prediction mode and associated names	130
Table 8-2 – Specification of modeIdx	132
Table 8-3 – Specification of IntraPredModeC when ChromaArrayType is equal to 2.....	132
Table 8-4 – Specification of intraHorVerDistThres[nTbS] for various transform block sizes	137
Table 8-5 – Specification of intraPredAngle	139
Table 8-6 – Specification of invAngle.....	139
Table 8-7 – Specification of l0CandIdx and l1CandIdx	155

Table 8-8 – Assignment of the luma prediction sample <code>predSampleLX_L</code>	167
Table 8-9 – Assignment of the chroma prediction sample <code>predSampleLX_C</code> for (X, Y) being replaced by (1, b), (2, c), (3, d), (4, e), (5, f), (6, g) and (7, h), respectively	169
Table 8-10 – Specification of <code>Q_{pC}</code> as a function of <code>qPi</code> for <code>ChromaArrayType</code> equal to 1.....	176
Table 8-11 – Name of association to <code>edgeType</code>	185
Table 8-12 – Derivation of threshold variables β' and t_C' from input Q	194
Table 8-13 – Specification of <code>hPos</code> and <code>vPos</code> according to the sample adaptive offset class	200
Table 9-1 – Bit strings with "prefix" and "suffix" bits and assignment to <code>codeNum</code> ranges (informative)	201
Table 9-2 – Exp-Golomb bit strings and <code>codeNum</code> in explicit form and used as <code>ue(v)</code> (informative).....	202
Table 9-3 – Assignment of syntax element to <code>codeNum</code> for signed Exp-Golomb coded syntax elements <code>se(v)</code>	202
Table 9-4 – Association of <code>ctxIdx</code> and syntax elements for each <code>initializationType</code> in the initialization process	207
Table 9-5 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>sao_merge_left_flag</code> and <code>sao_merge_up_flag</code>	209
Table 9-6 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>sao_type_idx_luma</code> and <code>sao_type_idx_chroma</code>	209
Table 9-7 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>split_cu_flag</code>	209
Table 9-8 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>cu_transquant_bypass_flag</code>	209
Table 9-9 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>cu_skip_flag</code>	209
Table 9-10 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>pred_mode_flag</code>	209
Table 9-11 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>part_mode</code>	210
Table 9-12 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>prev_intra_luma_pred_flag</code>	210
Table 9-13 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>intra_chroma_pred_mode</code>	210
Table 9-14 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>rqt_root_cbf</code>	210
Table 9-15 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>merge_flag</code>	210
Table 9-16 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>merge_idx</code>	210
Table 9-17 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>inter_pred_idc</code>	211
Table 9-18 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>ref_idx_l0</code> and <code>ref_idx_l1</code>	211
Table 9-19 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>mvp_l0_flag</code> and <code>mvp_l1_flag</code>	211
Table 9-20 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>split_transform_flag</code>	211
Table 9-21 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>cbf_luma</code>	211
Table 9-22 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>cbf_cb</code> and <code>cbf_cr</code>	211
Table 9-23 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>abs_mvd_greater0_flag</code> and <code>abs_mvd_greater1_flag</code>	212
Table 9-24 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>cu_qp_delta_abs</code>	212
Table 9-25 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>transform_skip_flag</code>	212
Table 9-26 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>last_sig_coeff_x_prefix</code>	212
Table 9-27 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>last_sig_coeff_y_prefix</code>	212
Table 9-28 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>coded_sub_block_flag</code>	213
Table 9-29 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>sig_coeff_flag</code>	213
Table 9-30 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>coeff_abs_level_greater1_flag</code>	213
Table 9-31 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>coeff_abs_level_greater2_flag</code>	214
Table 9-32 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>explicit_rdpem_flag</code>	214
Table 9-33 – Values of <code>initValue</code> for <code>ctxIdx</code> of <code>explicit_rdpem_dir_flag</code>	214

Table 9-34 – Values of initValue for ctxIdx of cu_chroma_qp_offset_flag.....	214
Table 9-35 – Values of initValue for ctxIdx of cu_chroma_qp_offset_idx.....	214
Table 9-36 – Values of initValue for ctxIdx of log2_res_scale_abs_plus1	215
Table 9-37 – Values of initValue for ctxIdx of res_scale_sign_flag	215
Table 9-38 – Values of initValue for ctxIdx of palette_mode_flag.....	215
Table 9-39 – Values of initValue for ctxIdx of tu_residual_act_flag	215
Table 9-40 – Values of initValue for ctxIdx of palette_run_prefix	215
Table 9-41 – Values of initValue for ctxIdx of copy_above_palette_indices_flag and copy_above_indices_for_final_run_flag	216
Table 9-42 – Values of initValue for ctxIdx of palette_transpose_flag.....	216
Table 9-43 – Syntax elements and associated binarizations	218
Table 9-44 – Bin string of the unary binarization (informative).....	221
Table 9-45 – Binarization for part_mode.....	223
Table 9-46 – Binarization for intra_chroma_pred_mode.....	224
Table 9-47 – Binarization for inter_pred_idc	224
Table 9-48 – Assignment of ctxInc to syntax elements with context coded bins	228
Table 9-49 – Specification of ctxInc using left and above syntax elements	230
Table 9-50 – Specification of ctxIdxMap[i]	232
Table 9-51 – Specification of ctxIdxMap[copy_above_palette_indices_flag][binIdx]	234
Table 9-52 – Specification of rangeTabLps depending on the values of pStateIdx and qRangeIdx	238
Table 9-53 – State transition table	239
Table A.1 – Allowed values for syntax elements in the format range extensions profiles	253
Table A.2 – Bitstream indications for conformance to format range extensions profiles.....	254
Table A.3 – Bitstream indications for conformance to high throughput profiles	257
Table A.4 – Allowed values for syntax elements in the screen content coding extensions profiles	258
Table A.5 – Bitstream indications for conformance to screen content coding extensions profiles	259
Table A.6 – Allowed values for syntax elements in the high throughput screen content coding extensions profiles	261
Table A.7 – Bitstream indications for conformance to high throughput screen content coding extensions profiles	262
Table A.8 – General tier and level limits	264
Table A.9 – Tier and level limits for the video profiles.....	266
Table A.10 – Specification of CpbVclFactor, CpbNalFactor, FormatCapabilityFactor and MinCrScaleFactor.....	267
Table A.11 – Maximum picture rates (pictures per second) at level 1 to 4.1 for some example picture sizes when MinCbSizeY is equal to 64.....	269
Table A.12 – Maximum picture rates (pictures per second) at level 5 to 6.2 for some example picture sizes when MinCbSizeY is equal to 64.....	270
Table D.1 – Persistence scope of SEI messages (informative).....	318
Table D.2 – Interpretation of pic_struct.....	326
Table D.3 – scene_transition_type values	333
Table D.4 – film_grain_model_id values	336
Table D.5 – blending_mode_id values	337
Table D.6 – filter_hint_type values	342

Table D.7 – Interpretation of camera_iso_speed_idc and exposure_idx_idc	345
Table D.8 – Definition of frame_packing_arrangement_type	347
Table D.9 – Definition of content_interpretation_type.....	348
Table D.10 – Interpretation of hash_type	355
Table D.11 – Definition of counting_type[i] values	362
Table D.12 – Definition of segmented_rect_content_interpretation_type.....	366
Table D.13 – ver_chroma_filter_idc values.....	372
Table D.14 – hor_chroma_filter_idc values	373
Table D.15 – Chroma sampling format indicated by target_format_idc	373
Table D.16 – Constraints on the value of num_vertical_filters	374
Table D.17 – Constraints on the value of num_horizontal_filters	374
Table D.18 – Values of verFilterCoeff and verTapLength when ver_chroma_filter_idc is equal to 2.....	375
Table D.19 – Values of horFilterCoeff and horTapLength when hor_chroma_filter_idc is equal to 2.....	375
Table D.20 – Usage of chroma filter in the vertical direction	378
Table D.21 – Usage of chroma filter in the horizontal direction	380
Table D.22 – rwp_transform_type[i] values.....	396
Table D.23 – Interpretation of manifest_sei_description[i].....	411
Table E.1 – Interpretation of sample aspect ratio indicator	421
Table E.2 – Meaning of video_format.....	422
Table E.3 – Colour primaries interpretation using the colour_primaries syntax element.....	423
Table E.4 – Transfer characteristics interpretation using the transfer_characteristics syntax element	424
Table E.5 – Matrix coefficients interpretation using the matrix_coeffs syntax element.....	431
Table E.6 – Definition of HorizontalOffsetC and VerticalOffsetC as a function of chroma_format_idc and ChromaLocType.....	433
Table E.7 – Divisor for computation of DpbOutputElementalInterval[n]	439
Table F.1 – Mapping of ScalabiltyId to scalability dimensions.....	465
Table F.2 – Mapping of AuxId to the type of auxiliary pictures	467

Foreword

The International Telecommunication Union (ITU) is the United Nations specialized agency in the field of telecommunications. The ITU Telecommunication Standardization Sector (ITU-T) is a permanent organ of ITU. ITU-T is responsible for studying technical, operating and tariff questions and issuing Recommendations on them with a view to standardizing telecommunications on a world-wide basis. The World Telecommunication Standardization Assembly (WTSA), which meets every four years, establishes the topics for study by the ITU-T study groups that, in turn, produce Recommendations on these topics. The approval of ITU-T Recommendations is covered by the procedure laid down in WTSA Resolution 1. In some areas of information technology that fall within ITU-T's purview, the necessary standards are prepared on a collaborative basis with ISO and IEC.

ISO (the International Organization for Standardization) and IEC (the International Electrotechnical Commission) form the specialized system for world-wide standardization. National Bodies that are members of ISO and IEC participate in the development of International Standards through technical committees established by the respective organization to deal with particular fields of technical activity. ISO and IEC technical committees collaborate in fields of mutual interest. Other international organizations, governmental and non-governmental, in liaison with ISO and IEC, also take part in the work. In the field of information technology, ISO and IEC have established a joint technical committee, ISO/IEC JTC 1. Draft International Standards adopted by the joint technical committee are circulated to national bodies for voting. Publication as an International Standard requires approval by at least 75% of the national bodies casting a vote.

This Recommendation | International Standard was prepared jointly by ITU-T SG 16 Question 6/16, also known as VCEG (Video Coding Experts Group), and by the working groups of ISO/IEC JTC 1/SC 29 known as MPEG (Moving Picture Experts Group). VCEG was formed in 1997 to maintain prior ITU-T video coding standards and develop new video coding standard(s) appropriate for a wide range of conversational and non-conversational services. MPEG was formed in 1988 to establish standards for coding of moving pictures and associated audio for various applications such as digital storage media, distribution, and communication.

In this Recommendation | International Standard Annexes A through I contain normative requirements and are an integral part of this Recommendation | International Standard.

High efficiency video coding

0 Introduction

0.1 General

This clause and its subclauses do not form an integral part of this Recommendation | International Standard.

0.2 Prologue

As the costs for both processing power and memory have reduced, network support for coded video data has diversified, and advances in video coding technology have progressed, the need has arisen for an industry standard for compressed video representation with substantially increased coding efficiency and enhanced robustness to network environments. Toward these ends the ITU-T Video Coding Experts Group (VCEG) and the ISO/IEC Moving Picture Experts Group (MPEG) formed a Joint Collaborative Team on Video Coding (JCT-VC) in 2010 and a Joint Collaborative Team on 3D Video Coding Extension Development (JCT-3V) in 2012 for development of a new Recommendation | International Standard. This Recommendation | International Standard was developed in the JCT-VC and the JCT-3V until 2020, when the responsibility for further maintenance and enhancement of the standard was transferred to another joint collaborative team of the same organizations called the Joint Video Experts Team (JVET).

0.3 Purpose

This Recommendation | International Standard was developed in response to the growing need for higher compression of moving pictures for various applications such as videoconferencing, digital storage media, television broadcasting, internet streaming, and communications. It is also designed to enable the use of the coded video representation in a flexible manner for a wide variety of network environments as well as to enable the use of multi-core parallel encoding and decoding devices. The use of this Recommendation | International Standard allows motion video to be manipulated as a form of computer data and to be stored on various storage media, transmitted and received over existing and future networks and distributed on existing and future broadcasting channels. Supports for higher bit depths and enhanced chroma formats, including the use of full-resolution chroma are provided. Support for scalability enables video transmission on networks with varying transmission conditions and other scenarios involving multiple bit rate services. Support for multiview enables representation of video content with multiple camera views and optional auxiliary information. Support for 3D enables joint representation of video content and depth information with multiple camera views.

0.4 Applications

This Recommendation | International Standard is designed to cover a broad range of applications for video content including but not limited to the following:

- Broadcast (cable TV on optical networks / copper, satellite, terrestrial, etc.)
- Camcorders
- Content production and distribution
- Digital cinema
- Home cinema
- Internet streaming, download and play
- Medical imaging
- Mobile streaming, broadcast and communications
- Real-time conversational services (videoconferencing, videophone, telepresence, etc.)
- Remote video surveillance
- Storage media (optical disks, digital video tape recorder, etc.)
- Wireless display

0.5 Publication and versions of this Specification

This Specification has been jointly developed by ITU-T Video Coding Experts Group (VCEG) and the ISO/IEC Moving Picture Experts Group (MPEG). It is published as technically-aligned twin text in both ITU-T and ISO/IEC. As the basis text has been drafted to become both an ITU-T Recommendation and an ISO/IEC International Standard, the term "Specification" (with capitalization to indicate that it refers to the whole of the text) is used herein when the text refers to itself.

Rec. ITU-T H.265 | ISO/IEC 23008-2 version 1 refers to the first approved version of this Recommendation | International Standard. The first edition published by ITU-T as Rec. ITU-T H.265 (04/2013) and by ISO/IEC as ISO/IEC 23008-2:2013 corresponded to the first version.

Rec. ITU-T H.265 | ISO/IEC 23008-2 version 2 refers to the integrated text additionally containing format range extensions, scalability extensions, multiview extensions, additional supplement enhancement information, and corrections to various minor defects in the prior content of the Specification. The second edition published by ITU-T as Rec. H.265 (10/2014) and by ISO/IEC as ISO/IEC 23008-2:2015 corresponded to the second version.

Rec. ITU-T H.265 | ISO/IEC 23008-2 version 3 refers to the integrated text additionally containing 3D extensions, additional supplement enhancement information, and corrections to various minor defects in the prior content of the Specification. The third edition published by ITU-T as Rec. H.265 (04/2015) corresponded to the third version.

Rec. ITU-T H.265 | ISO/IEC 23008-2 version 4 refers to the integrated text additionally containing screen content coding extensions profiles, scalable range extensions profiles, additional high throughput profiles, additional supplement enhancement information, additional colour representation identifiers, and corrections to various minor defects in the prior content of the Specification. The fourth edition published by ITU-T as Rec. H.265 (12/2016) and by ISO/IEC as ISO/IEC 23008-2:2017 corresponded to the fourth version.

Rec. ITU-T H.265 | ISO/IEC 23008-2 version 5 refers to the integrated text additionally containing additional SEI messages that include omnidirectional video SEI messages, a Monochrome 10 profile, a Main 10 Still Picture profile, and corrections to various minor defects in the prior content of the Specification. The fifth edition published by ITU-T as Rec. H.265 (02/2018) corresponded to the fifth version.

Rec. ITU-T H.265 | ISO/IEC 23008-2 version 6 refers to the integrated text additionally containing additional SEI messages for SEI manifest and SEI prefix, along with some corrections to the existing specification text. The sixth edition published by ITU-T as Rec. H.265 (06/2019) corresponded to the sixth version.

Rec. ITU-T H.265 | ISO/IEC 23008-2 version 7 refers to the integrated text additionally containing the fisheye video information SEI message and the annotated regions SEI message, along with some corrections to the existing specification text. The seventh edition published by ITU-T as Rec. H.265 (11/2019) corresponded to the seventh version.

Rec. ITU-T H.265 | ISO/IEC 23008-2 version 8 (the current version) refers to the integrated text additionally containing the shutter interval information SEI message, along with some corrections to the existing specification text.

0.6 Profiles, tiers and levels

This Recommendation | International Standard is designed to be generic in the sense that it serves a wide range of applications, bit rates, resolutions, qualities and services. Applications should cover, among other things, digital storage media, television broadcasting and real-time communications. In the course of creating this Specification, various requirements from typical applications have been considered, necessary algorithmic elements have been developed, and these have been integrated into a single syntax. Hence, this Specification will facilitate video data interchange among different applications.

Considering the practicality of implementing the full syntax of this Specification, however, a limited number of subsets of the syntax are also stipulated by means of "profiles", "tiers" and "levels". These and other related terms are formally defined in clause 3.

A "profile" is a subset of the entire bitstream syntax that is specified in this Recommendation | International Standard. Within the bounds imposed by the syntax of a given profile, it is still possible to require a very large variation in the performance of encoders and decoders depending upon the values taken by syntax elements in the bitstream such as the specified size of the decoded pictures. In many applications, it is currently neither practical nor economical to implement a decoder capable of dealing with all hypothetical uses of the syntax within a particular profile.

In order to deal with this problem, "tiers" and "levels" are specified within each profile. A level of a tier is a specified set of constraints imposed on values of the syntax elements in the bitstream. These constraints may be simple limits on values. Alternatively they may take the form of constraints on arithmetic combinations of values (e.g., picture width multiplied by picture height multiplied by number of pictures decoded per second). A level specified for a lower tier is more constrained than a level specified for a higher tier.

Coded video content conforming to this Recommendation | International Standard uses a common syntax. In order to achieve a subset of the complete syntax, flags, parameters and other syntax elements are included in the bitstream that signal the presence or absence of syntactic elements that occur later in the bitstream.

0.7 Overview of the design characteristics

The coded representation specified in the syntax is designed to enable a high compression capability for a desired image or video quality. The algorithm is typically not lossless, as the exact source sample values are typically not preserved through the encoding and decoding processes. A number of techniques may be used to achieve highly efficient compression. Encoding algorithms (not specified in this Recommendation | International Standard) may select between inter and intra coding for block-shaped regions of each picture. Inter coding uses motion vectors for block-based inter prediction to exploit temporal statistical dependencies between different pictures. Intra coding uses various spatial prediction modes to exploit spatial statistical dependencies in the source signal for a single picture. Motion vectors and intra prediction modes may be specified for a variety of block sizes in the picture. The prediction residual may then be further compressed using a transform to remove spatial correlation inside the transform block before it is quantized, producing a possibly irreversible process that typically discards less important visual information while forming a close approximation to the source samples. Finally, the motion vectors or intra prediction modes may also be further compressed using a variety of prediction mechanisms, and, after prediction, are combined with the quantized transform coefficient information and encoded using arithmetic coding.

0.8 How to read this Specification

It is suggested that the reader starts with clause 1 (Scope) and moves on to clause 3 (Definitions). Clause 6 should be read for the geometrical relationship of the source, input and output of the decoder. Clause 7 (Syntax and semantics) specifies the order to parse syntax elements from the bitstream. See clauses 7.1–7.3 for syntactical order and see clause 7.4 for semantics; e.g., the scope, restrictions and conditions that are imposed on the syntax elements. The actual parsing for most syntax elements is specified in clause 9 (Parsing process). Clause 10 (Sub-bitstream extraction process) specifies the sub-bitstream extraction process. Finally, clause 8 (Decoding process) specifies how the syntax elements are mapped into decoded samples. Throughout reading this Specification, the reader should refer to clauses 2 (Normative references), 4 (Abbreviations), and 5 (Conventions) as needed. Annexes A through I also form an integral part of this Recommendation | International Standard.

Annex A specifies profiles each being tailored to certain application domains, and defines the so-called tiers and levels of the profiles. Annex B specifies syntax and semantics of a byte stream format for delivery of coded video as an ordered stream of bytes. Annex C specifies the hypothetical reference decoder, bitstream conformance, decoder conformance and the use of the hypothetical reference decoder to check bitstream and decoder conformance. Annex D specifies syntax and semantics for supplemental enhancement information message payloads. Annex E specifies syntax and semantics of the video usability information parameters of the sequence parameter set. Annex F specifies general multi-layer support for bitstreams and decoders. Annex G contains support for multiview coding. Annex H contains support for scalability. Annex I contains support for 3D coding.

Throughout this Specification, statements appearing with the preamble "NOTE –" are informative and are not an integral part of this Recommendation | International Standard.

1 Scope

This Recommendation | International Standard specifies high efficiency video coding.

2 Normative references

2.1 General

The following Recommendations and International Standards contain provisions which, through reference in this text, constitute provisions of this Recommendation | International Standard. At the time of publication, the editions indicated were valid. All Recommendations and Standards are subject to revision, and parties to agreements based on this Recommendation | International Standard are encouraged to investigate the possibility of applying the most recent edition of the Recommendations and Standards listed below. Members of IEC and ISO maintain registers of currently valid International Standards. The Telecommunication Standardization Bureau of the ITU maintains a list of currently valid ITU-T Recommendations.

3 Definitions

For the purposes of this Recommendation | International Standard, the following definitions apply:

- 3.1 access unit:** A set of *NAL units* that are associated with each other according to a specified classification rule, are consecutive in *decoding order*, and contain exactly one *coded picture* with *nuh_layer_id* equal to 0.
- NOTE 1 – In addition to containing the video coding layer (VCL) *NAL units* of the coded picture with *nuh_layer_id* equal to 0, an access unit may also contain non-VCL *NAL units*. The decoding of an access unit with the decoding process specified in clause 8 always results in a decoded picture with *nuh_layer_id* equal to 0.
- NOTE 2 – An access unit is defined differently in Annex F and does not need to contain a coded picture with *nuh_layer_id* equal to 0.
- 3.2 AC transform coefficient:** Any *transform coefficient* for which the *frequency index* in at least one of the two dimensions is non-zero.
- 3.3 associated IRAP picture:** The previous *IRAP picture* in *decoding order* (when present).
- 3.4 associated non-VCL NAL unit:** A *non-VCL NAL unit* (when present) for a *VCL NAL unit* where the *VCL NAL unit* is the *associated VCL NAL unit* of the *non-VCL NAL unit*.
- 3.5 associated VCL NAL unit:** The preceding *VCL NAL unit* in *decoding order* for a *non-VCL NAL unit* with *nal_unit_type* equal to *EOS_NUT*, *EOB_NUT*, *FD_NUT* or *SUFFIX_SEI_NUT*, or in the ranges of *RSV_NVCL45*..*RSV_NVCL47* or *UNSPEC56*..*UNSPEC63*; or otherwise the next *VCL NAL unit* in *decoding order*.
- 3.6 azimuth circle:** A circle on a sphere connecting all points with the same azimuth value.
- NOTE – An azimuth circle is always a *great circle* like a longitude line on the earth.
- 3.7 base layer:** A *layer* in which all *NAL units* have *nuh_layer_id* equal to 0.
- 3.8 bin:** One bit of a *bin string*.
- 3.9 binarization:** A set of *bin strings* for all possible values of a *syntax element*.
- 3.10 binarization process:** A unique mapping process of all possible values of a *syntax element* onto a set of *bin strings*.
- 3.11 bin string:** An intermediate binary representation of values of *syntax elements* from the *binarization* of the *syntax element*.
- 3.12 bi-predictive (B) slice:** A *slice* that is decoded using *intra prediction* or using *inter prediction* with at most two *motion vectors* and *reference indices* to *predict* the sample values of each *block*.

- 3.13 bitstream:** A sequence of bits, in the form of a *NAL unit stream* or a *byte stream*, that forms the representation of *coded pictures* and associated data forming one or more coded video sequences (*CVSs*).
- 3.14 block:** An MxN (M-column by N-row) array of samples, or an MxN array of *transform coefficients*.
- 3.15 broken link:** A location in a *bitstream* at which it is indicated that some subsequent *pictures* in *decoding order* may contain serious visual artefacts due to unspecified operations performed in the generation of the *bitstream*.
- 3.16 broken link access (BLA) access unit:** An *access unit* in which the *coded picture* with *nuh_layer_id* equal to 0 is a *BLA picture*.
- 3.17 broken link access (BLA) picture:** An *IRAP picture* for which each *VCL NAL unit* has *nal_unit_type* equal to BLA_W_LP, BLA_W_RADL, or BLA_N_LP.
- NOTE – A BLA picture does not refer to any pictures other than itself for inter prediction in its decoding process, and may be the first picture in the bitstream in decoding order, or may appear later in the bitstream. Each BLA picture begins a new CVS, and has the same effect on the decoding process as an instantaneous decoding refresh (IDR) picture. However, a BLA picture contains syntax elements that specify a non-empty RPS. When a BLA picture for which each VCL NAL unit has *nal_unit_type* equal to BLA_W_LP, it may have associated random access skipped leading (RASL) pictures, which are not output by the decoder and may not be decodable, as they may contain references to pictures that are not present in the bitstream. When a BLA picture for which each VCL NAL unit has *nal_unit_type* equal to BLA_W_LP, it may also have associated RADL pictures, which are specified to be decoded. When a BLA picture for which each VCL NAL unit has *nal_unit_type* equal to BLA_W_RADL, it does not have associated RASL pictures but may have associated random access decodable leading (RADL) pictures. When a BLA picture for which each VCL NAL unit has *nal_unit_type* equal to BLA_N_LP, it does not have any associated leading pictures.
- 3.18 buffering period:** The set of *access units* starting with an *access unit* that contains a buffering period supplemental enhancement information (SEI) message and containing all subsequent *access units* in *decoding order* up to but not including the next *access unit* (when present) that contains a buffering period SEI message.
- 3.19 byte:** A sequence of 8 bits, within which, when written or read as a sequence of bit values, the left-most and right-most bits represent the most and least significant bits, respectively.
- 3.20 byte-aligned:** A position in a *bitstream* is byte-aligned when the position is an integer multiple of 8 bits from the position of the first bit in the *bitstream*, and a bit or *byte* or *syntax element* is said to be byte-aligned when the position at which it appears in a *bitstream* is byte-aligned.
- 3.21 byte stream:** An encapsulation of a *NAL unit stream* containing *start code prefixes* and *NAL units* as specified in Annex B.
- 3.22 can:** A term used to refer to behaviour that is allowed, but not necessarily required.
- 3.23 chroma:** An adjective, represented by the symbols Cb and Cr, specifying that a sample array or single sample is representing one of the two colour difference signals related to the primary colours.
- NOTE – The term chroma is used rather than the term chrominance in order to avoid the implication of the use of linear light transfer characteristics that is often associated with the term chrominance.
- 3.24 clean random access (CRA) access unit:** An *access unit* in which the *coded picture* with *nuh_layer_id* equal to 0 is a *CRA picture*.
- 3.25 clean random access (CRA) picture:** An *IRAP picture* for which each *VCL NAL unit* has *nal_unit_type* equal to CRA_NUT.
- NOTE – A CRA picture does not refer to any pictures other than itself for inter prediction in its decoding process, and may be the first picture in the bitstream in decoding order, or may appear later in the bitstream. A CRA picture may have associated RADL or RASL pictures. As with a BLA picture, a CRA picture may contain syntax elements that specify a non-empty RPS. When a CRA picture has *NoRaslOutputFlag* equal to 1, the associated RASL pictures are not output by the decoder, because they may not be decodable, as they may contain references to pictures that are not present in the bitstream.
- 3.26 coded picture:** A *coded representation* of a *picture* containing all *CTUs* of the *picture*.
- 3.27 coded picture buffer (CPB):** A first-in first-out buffer containing *decoding units* in *decoding order* specified in the *hypothetical reference decoder* in Annex C.
- 3.28 coded representation:** A data element as represented in its coded form.
- 3.29 coded slice segment NAL unit:** A *NAL unit* that has *nal_unit_type* in the range of TRAIL_N to RASL_R, inclusive, or in the range of BLA_W_LP to RSV_IRAP_VCL23, inclusive, which indicates that the *NAL unit* contains a coded *slice segment*.
- 3.30 coded layer-wise video sequence (CLVS):** A sequence of *pictures* and the associated non-VCL *NAL units* of the *base layer* of a *coded video sequence (CVS)*.

- 3.31 coded video sequence (CVS):** A sequence of *access units* that consists, in *decoding order*, of an *IRAP access unit* with NoRasOutputFlag equal to 1, followed by zero or more *access units* that are not *IRAP access units* with NoRasOutputFlag equal to 1, including all subsequent *access units* up to but not including any subsequent *access unit* that is an *IRAP access unit* with NoRasOutputFlag equal to 1.
- NOTE – An *IRAP access unit* may be an *IDR access unit*, a *BLA access unit*, or a *CRA access unit*. The value of NoRasOutputFlag is equal to 1 for each *IDR access unit*, each *BLA access unit*, and each *CRA access unit* that is the first access unit in the bitstream in decoding order, is the first access unit that follows an end of sequence NAL unit in decoding order, or has HandleCraAsBlaFlag equal to 1.
- 3.32 coded video sequence group (CVSG):** One or more consecutive *CVSs* in *decoding order* that collectively consist of an *IRAP access unit* that activates a video parameter set (VPS) RBSP firstVpsRbsp that was not already active followed by all subsequent *access units*, in *decoding order*, for which firstVpsRbsp is the active VPS raw byte sequence payload (RBSP) up to the end of the *bitstream* or up to but excluding the *access unit* that activates a different VPS RBSP than firstVpsRbsp, whichever is earlier in *decoding order*.
- 3.33 coding block:** An $N \times N$ *block* of samples for some value of N such that the division of a *CTB* into *coding blocks* is a *partitioning*.
- 3.34 coding tree block (CTB):** An $N \times N$ *block* of samples for some value of N such that the division of a *component* into *CTBs* is a *partitioning*.
- 3.35 coding tree unit (CTU):** A *CTB* of *luma* samples, two corresponding *CTBs* of *chroma* samples of a *picture* that has three sample arrays, or a *CTB* of samples of a monochrome *picture* or a *picture* that is coded using three separate colour planes and *syntax structures* used to code the samples.
- 3.36 coding unit:** A *coding block* of *luma* samples, two corresponding *coding blocks* of *chroma* samples of a *picture* that has three sample arrays, or a *coding block* of samples of a monochrome *picture* or a *picture* that is coded using three separate colour planes and *syntax structures* used to code the samples.
- 3.37 component:** An array or single sample from one of the three arrays (*luma* and two *chroma*) that compose a *picture* in 4:2:0, 4:2:2, or 4:4:4 colour format or the array or a single sample of the array that compose a *picture* in monochrome format.
- 3.38 constituent picture:** A part of a spatially *frame*-packed stereoscopic *picture* that corresponds to one view, or a *picture* itself when *frame* packing is not in use or the temporal interleaving *frame* packing arrangement is in use.
- 3.39 context variable:** A variable specified for the *adaptive binary arithmetic decoding process* of a *bin* by an equation containing recently decoded *bins*.
- 3.40 cropped decoded picture:** The result of cropping a *decoded picture* based on the conformance cropping window specified in the *sequence parameter set (SPS)* that is referred to by the corresponding *coded picture*.
- 3.41 decoded picture:** A *decoded picture* is derived by decoding a *coded picture*.
- 3.42 decoded picture buffer (DPB):** A buffer holding *decoded pictures* for reference, output reordering, or output delay specified for the *hypothetical reference decoder* in Annex C.
- 3.43 decoder:** An embodiment of a *decoding process*.
- 3.44 decoder under test (DUT):** A *decoder* that is tested for conformance to this Specification by operating the *hypothetical stream scheduler* to deliver a conforming *bitstream* to the *decoder* and to the *hypothetical reference decoder* and comparing the values and timing or order of the output of the two *decoders*.
- 3.45 decoding order:** The order in which *syntax elements* are processed by the *decoding process*.
- 3.46 decoding process:** The process specified in this Specification that reads a *bitstream* and derives *decoded pictures* from it.
- 3.47 decoding unit:** An *access unit* if SubPicHrdFlag is equal to 0 or a subset of an *access unit* otherwise, consisting of one or more *VCL NAL units* in an *access unit* and the *associated non-VCL NAL units*.
- 3.48 dependent slice segment:** A *slice segment* for which the values of some *syntax elements* of the *slice segment header* are inferred from the values for the preceding *independent slice segment* in *decoding order*.
- 3.49 display process:** A process not specified in this Specification having, as its input, the *cropped decoded pictures* that are the output of the *decoding process*.
- 3.50 elementary stream:** A sequence of one or more *bitstreams*.
- NOTE – An elementary stream that consists of two or more *bitstreams* would typically have been formed by splicing together two or more *bitstreams* (or parts thereof).

- 3.51 elevation circle:** A circle on a sphere connecting all points with the same elevation value.
- NOTE – An elevation circle is similar to a latitude line on the earth. Except when the elevation value is zero, an elevation circle is not a *great circle* like a longitude circle on the earth.
- 3.52 emulation prevention byte:** A byte equal to 0x03 that is present within a *NAL unit* when the *syntax elements* of the *bitstream* form certain patterns of *byte* values in a manner that ensures that no sequence of consecutive *byte-aligned bytes* in the *NAL unit* can contain a *start code prefix*.
- 3.53 encoder:** An embodiment of an *encoding process*.
- 3.54 encoding process:** A process not specified in this Specification that produces a *bitstream* conforming to this Specification.
- 3.55 field:** An assembly of alternative rows of samples of a *frame*.
- 3.56 filler data NAL units:** *NAL units* with *nal_unit_type* equal to FD_NUT.
- 3.57 flag:** A variable or single-bit *syntax element* that can take one of the two possible values: 0 and 1.
- 3.58 frame:** The composition of a top *field* and a bottom *field*, where sample rows 0, 2, 4, ... originate from the top *field* and sample rows 1, 3, 5, ... originate from the bottom *field*.
- 3.59 frequency index:** A one-dimensional or two-dimensional index associated with a *transform coefficient* prior to the application of a *transform* in the *decoding process*.
- 3.60 global coordinate axes:** The coordinate axes associated with *omnidirectional video* that are associated with an externally referenceable position and orientation.
- NOTE – The global coordinate axes may correspond to the position and orientation of a device or rig used for omnidirectional audio/video acquisition as well as the position of an observer's head in the three-dimensional space of the *omnidirectional video* rendering environment.
- 3.61 great circle:** The intersection of a sphere and a plane that passes through the centre point of the sphere.
- NOTE – A great circle is also known as an orthodrome or Riemannian circle.
- 3.62 hypothetical reference decoder (HRD):** A hypothetical *decoder* model that specifies constraints on the variability of conforming *NAL unit streams* or conforming *byte streams* that an encoding process may produce.
- 3.63 hypothetical stream scheduler (HSS):** A hypothetical delivery mechanism used for checking the conformance of a *bitstream* or a *decoder* with regards to the timing and data flow of the input of a *bitstream* into the *hypothetical reference decoder*.
- 3.64 independent slice segment:** A *slice segment* for which the values of the *syntax elements* of the *slice segment header* are not inferred from the values for a preceding *slice segment*.
- 3.65 informative:** A term used to refer to content provided in this Specification that does not establish any mandatory requirements for conformance to this Specification and thus is not considered an integral part of this Specification.
- 3.66 instantaneous decoding refresh (IDR) access unit:** An *access unit* in which the *coded picture* with *nuh_layer_id* equal to 0 is an *IDR picture*.
- 3.67 instantaneous decoding refresh (IDR) picture:** An *IRAP picture* for which each *VCL NAL unit* has *nal_unit_type* equal to IDR_W_RADL or IDR_N_LP.
- NOTE – An IDR picture does not refer to any pictures other than itself for inter prediction in its decoding process, and may be the first picture in the bitstream in decoding order, or may appear later in the bitstream. Each IDR picture is the first picture of a CVS in decoding order. When an IDR picture for which each VCL NAL unit has *nal_unit_type* equal to IDR_W_RADL, it may have associated RADL pictures. When an IDR picture for which each VCL NAL unit has *nal_unit_type* equal to IDR_N_LP, it does not have any associated leading pictures. An IDR picture does not have associated RASL pictures.
- 3.68 inter coding:** Coding of a *coding block*, *slice*, or *picture* that uses *inter prediction*.
- 3.69 inter prediction:** A *prediction* derived in a manner that is dependent on data elements (e.g., sample values or motion vectors) of one or more *reference pictures*.
- NOTE – A prediction from a reference picture that is the current picture itself is also inter prediction.
- 3.70 intra coding:** Coding of a *coding block*, *slice*, or *picture* that uses *intra prediction*.
- 3.71 intra prediction:** A *prediction* derived from only data elements (e.g., sample values) of the same decoded *slice* without referring to a *reference picture*.

- 3.72 intra random access point (IRAP) access unit:** An *access unit* in which the *coded picture* with *nuh_layer_id* equal to 0 is an *IRAP picture*.
- 3.73 intra random access point (IRAP) picture:** A *coded picture* for which each *VCL NAL unit* has *nal_unit_type* in the range of BLA_W_LP to RSV_IRAP_VCL23, inclusive.
- NOTE – An IRAP picture does not refer to any pictures other than itself for inter prediction in its decoding process, and may be a BLA picture, a CRA picture or an IDR picture. The first picture in the bitstream in decoding order must be an IRAP picture. Provided the necessary parameter sets are available when they need to be activated, the IRAP picture and all subsequent non-RASL pictures in decoding order can be correctly decoded without performing the decoding process of any pictures that precede the IRAP picture in decoding order. There may be pictures in a bitstream that do not refer to any pictures other than itself for inter prediction in its decoding process that are not IRAP pictures.
- 3.74 intra (I) slice:** A *slice* that is decoded using *intra prediction* only.
- 3.75 layer:** A set of *VCL NAL units* that all have a particular value of *nuh_layer_id* and the *associated non-VCL NAL units*, or one of a set of syntactical structures having a hierarchical relationship.
- NOTE – Depending on the context, either the first layer concept or the second layer concept applies. The first layer concept is also referred to as a scalable layer, wherein a layer may be a spatial scalable layer, a quality scalable layer, a view, etc. A temporal true subset of a scalable layer is not referred to as a layer but referred to as a sub-layer or temporal sub-layer. The second layer concept is also referred to as a coding layer, wherein higher layers contain lower layers, and the coding layers are the CVS, picture, slice, slice segment, and CTU layers.
- 3.76 layer identifier list:** A list of *nuh_layer_id* values that is associated with a *layer set* or an *operation point* and can be used as an input to the *sub-bitstream extraction process*.
- 3.77 layer set:** A set of *layers* represented within a *bitstream* created from another *bitstream* by operation of the *sub-bitstream extraction process* with the another *bitstream*, the target highest TemporalId equal to 6, and the target *layer identifier list* equal to the *layer identifier list* associated with the layer set as inputs.
- 3.78 leading picture:** A *picture* that precedes the *associated IRAP picture* in *output order*.
- 3.79 leaf:** A terminating node of a tree that is a root node of a tree of depth 0.
- 3.80 level:** A defined set of constraints on the values that may be taken by the *syntax elements* and variables of this Specification, or the value of a *transform coefficient* prior to *scaling*.
- NOTE – The same set of levels is defined for all profiles, with most aspects of the definition of each level being in common across different profiles. Individual implementations may, within the specified constraints, support a different level for each supported profile.
- 3.81 list 0 (list 1) motion vector:** A *motion vector* associated with a *reference index* pointing into *reference picture list 0 (list 1)*.
- 3.82 list 0 (list 1) prediction:** *Inter prediction* of the content of a *slice* using a *reference index* pointing into *reference picture list 0 (list 1)*.
- 3.83 local coordinate axes:** The coordinate axes having a specified rotation relationship relative to the *global coordinate axes*.
- 3.84 long-term reference picture:** A *picture* that is marked as "used for long-term reference".
- 3.85 long-term reference picture set:** The two reference picture set (RPS) lists that may contain long-term reference pictures.
- 3.86 luma:** An adjective, represented by the symbol or subscript Y or L, specifying that a sample array or single sample is representing the monochrome signal related to the primary colours.
- NOTE – The term luma is used rather than the term luminance in order to avoid the implication of the use of linear light transfer characteristics that is often associated with the term luminance. The symbol L is sometimes used instead of the symbol Y to avoid confusion with the symbol y as used for vertical location.
- 3.87 may:** A term that is used to refer to behaviour that is allowed, but not necessarily required.
- NOTE – In some places where the optional nature of the described behaviour is intended to be emphasized, the phrase "may or may not" is used to provide emphasis.
- 3.88 motion vector:** A two-dimensional vector used for *inter prediction* that provides an offset from the coordinates in the *decoded picture* to the coordinates in a *reference picture*.
- 3.89 must:** A term that is used in expressing an observation about a requirement or an implication of a requirement that is specified elsewhere in this Specification (used exclusively in an *informative* context).
- 3.90 network abstraction layer (NAL) unit:** A *syntax structure* containing an indication of the type of data to follow and *bytes* containing that data in the form of an *RBSP* interspersed as necessary with *emulation prevention bytes*.

- 3.91 network abstraction layer (NAL) unit stream:** A sequence of *NAL units*.
- 3.92 non-scalable-nested SEI message:** An SEI message that is not contained in a scalable nesting SEI message.
- 3.93 non-reference picture:** A *picture* that is marked as "unused for reference".
 NOTE – A non-reference picture contains samples that cannot be used for inter prediction in the decoding process of subsequent pictures in decoding order. In other words, once a picture is marked as "unused for reference", it can never be marked back as "used for reference".
- 3.94 non-VCL NAL unit:** A *NAL unit* that is not a *VCL NAL unit*.
- 3.95 note:** A term that is used to prefix *informative* remarks (used exclusively in an *informative* context).
- 3.96 omnidirectional video:** A video content in a format that enables rendering according to the user's viewing orientation, e.g., if viewed using a head-mounted device, or according to a user's desired *viewport*, reflecting a potentially rotated viewing position.
- 3.97 operation point:** A *bitstream* created from another *bitstream* by operation of the *sub-bitstream extraction process* with the another *bitstream*, a target highest TemporalId, and a target *layer identifier list* as inputs.
 NOTE – If the target highest TemporalId of an operation point is equal to the greatest value of TemporalId in the layer set associated with the target layer identification list, the operation point is identical to the layer set. Otherwise it is a subset of the layer set.
- 3.98 output order:** The order in which the *decoded pictures* are output from the *decoded picture buffer* (for the *decoded pictures* that are to be output from the *decoded picture buffer*).
- 3.99 output time:** A time when a *decoded picture* is to be output as specified by the *hypothetical reference decoder (HRD)* according to the output timing *decoded picture buffer (DPB)* operation.
- 3.100 packed region:** A region in a *region-wise packed picture* that is mapped to a *projected region* according to a *region-wise packing*.
- 3.101 parameter:** A *syntax element* of a *video parameter set (VPS)*, *sequence parameter set (SPS)* or *picture parameter set (PPS)*, or the second word of the defined term *quantization parameter*.
- 3.102 partitioning:** The division of a set into subsets such that each element of the set is in exactly one of the subsets.
- 3.103 picture:** An array of *luma* samples in monochrome format or an array of *luma* samples and two corresponding arrays of *chroma* samples in 4:2:0, 4:2:2, and 4:4:4 colour format.
 NOTE – A picture may be either a frame or a field. However, in one CVS, either all pictures are frames or all pictures are fields.
- 3.104 picture parameter set (PPS):** A *syntax structure* containing *syntax elements* that apply to zero or more entire *coded pictures* as determined by a *syntax element* found in each *slice segment header*.
- 3.105 picture order count (POC):** A variable that is associated with each *picture*, uniquely identifies the associated *picture* among all *pictures* in the CVS, and, when the associated *picture* is to be output from the *decoded picture buffer*, indicates the position of the associated *picture* in *output order* relative to the *output order* positions of the other *pictures* in the same CVS that are to be output from the *decoded picture buffer*.
- 3.106 picture unit:** A set of *NAL units* that contain all *VCL NAL units* of a *coded picture* and their *associated non-VCL NAL units*.
- 3.107 prediction:** An embodiment of the *prediction process*.
- 3.108 prediction block:** A rectangular MxN *block* of samples on which the same *prediction* is applied.
- 3.109 prediction process:** The use of a *predictor* to provide an estimate of the data element (e.g., sample value or motion vector) currently being decoded.
- 3.110 prediction unit:** A *prediction block* of *luma* samples, two corresponding *prediction blocks* of *chroma* samples of a *picture* that has three sample arrays, or a *prediction block* of samples of a monochrome *picture* or a *picture* that is coded using three separate colour planes and *syntax structures* used to predict the *prediction block* samples.
- 3.111 predictive (P) slice:** A *slice* that is decoded using *intra prediction* or using *inter prediction* with at most one *motion vector* and *reference index* to *predict* the sample values of each *block*.
- 3.112 predictor:** A combination of specified values or previously decoded data elements (e.g., sample value or motion vector) used in the *decoding process* of subsequent data elements.
- 3.113 prefix SEI message:** An SEI message that is contained in a *prefix SEI NAL unit*.
- 3.114 prefix SEI NAL unit:** An *SEI NAL unit* that has *nal_unit_type* equal to PREFIX_SEI_NUT.

- 3.115 profile:** A specified subset of the syntax of this Specification.
- 3.116 projected picture:** A picture that uses a *projection* format for *omnidirectional video*.
- 3.117 projected region:** A region in a *projected picture* that is mapped to a *packed region* according to a *region-wise packing*.
- 3.118 projection:** A specified correspondence between the colour samples of a *projected picture* and azimuth and elevation positions on a sphere.
- 3.119 pulse code modulation (PCM):** Coding of the samples of a *block* by directly representing the sample values without *prediction* or application of a transform.
- 3.120 quadtree:** A *tree* in which a parent node can be split into four child nodes, each of which may become parent node for another split into four child nodes.
- 3.121 quantization parameter:** A variable used by the *decoding process* for *scaling of transform coefficient levels*.
- 3.122 random access:** The act of starting the decoding process for a *bitstream* at a point other than the beginning of the stream.
- 3.123 random access decodable leading (RADL) access unit:** An *access unit* in which the *coded picture* with *nuh_layer_id* equal to 0 is a *RADL picture*.
- 3.124 random access decodable leading (RADL) picture:** A *coded picture* for which each *VCL NAL unit* has *nal_unit_type* equal to RADL_R or RADL_N.
 NOTE – All RADL pictures are leading pictures. RADL pictures are not used as reference pictures for the decoding process of trailing pictures of the same associated IRAP picture. When present, all RADL pictures precede, in decoding order, all trailing pictures of the same associated IRAP picture.
- 3.125 random access skipped leading (RASL) access unit:** An *access unit* in which the *coded picture* with *nuh_layer_id* equal to 0 is a *RASL picture*.
- 3.126 random access skipped leading (RASL) picture:** A *coded picture* for which each *VCL NAL unit* has *nal_unit_type* equal to RASL_R or RASL_N.
 NOTE – All RASL pictures are leading pictures of an associated BLA or CRA picture. When the associated IRAP picture has *NoRaslOutputFlag* equal to 1, the RASL picture is not output and may not be correctly decodable, as the RASL picture may contain references to pictures that are not present in the bitstream. RASL pictures are not used as reference pictures for the decoding process of non-RASL pictures. When present, all RASL pictures precede, in decoding order, all trailing pictures of the same associated IRAP picture.
- 3.127 raster scan:** A mapping of a rectangular two-dimensional pattern to a one-dimensional pattern such that the first entries in the one-dimensional pattern are from the first top row of the two-dimensional pattern scanned from left to right, followed similarly by the second, third, etc., rows of the pattern (going down) each scanned from left to right.
- 3.128 raw byte sequence payload (RBSP):** A *syntax structure* containing an integer number of *bytes* that is encapsulated in a *NAL unit* and that is either empty or has the form of a *string of data bits* containing *syntax elements* followed by an *RBSP stop bit* and zero or more subsequent bits equal to 0.
- 3.129 raw byte sequence payload (RBSP) stop bit:** A bit equal to 1 present within a *raw byte sequence payload (RBSP)* after a *string of data bits*, for which the location of the end within an *RBSP* can be identified by searching from the end of the *RBSP* for the *RBSP stop bit*, which is the last non-zero bit in the *RBSP*.
- 3.130 recovery point:** A point in the *bitstream* at which the recovery of an exact or an approximate representation of the *decoded pictures* represented by the *bitstream* is achieved after a *random access* or *broken link*.
- 3.131 reference index:** An index into a *reference picture list*.
- 3.132 reference picture:** A *picture* that is a *short-term reference picture* or a *long-term reference picture*.
 NOTE – A reference picture contains samples that may be used for inter prediction in the decoding process of subsequent pictures in decoding order.
- 3.133 reference picture list:** A list of *reference pictures* that is used for *inter prediction* of a *P* or *B slice*.
 NOTE – For the decoding process of a *P* slice, there is one reference picture list – reference picture list 0. For the decoding process of a *B* slice, there are two reference picture lists – reference picture list 0 and reference picture list 1.
- 3.134 reference picture list 0:** The *reference picture list* used for *inter prediction* of a *P* or the first *reference picture list* used for *inter prediction* of a *B slice*.
- 3.135 reference picture list 1:** The second *reference picture list* used for *inter prediction* of a *B slice*.

- 3.136 reference picture set (RPS):** A set of *reference pictures* associated with a *picture*, consisting of all *reference pictures* that are prior to the associated *picture* in *decoding order*, that may be used for *inter prediction* of the associated *picture* or any *picture* following the associated *picture* in *decoding order*.
- NOTE – The RPS of a picture consists of five RPS lists, three of which are to contain short-term reference pictures and the other two are to contain long-term reference pictures.
- 3.137 region-wise packed picture:** A decoded picture that contains one or more *packed regions*.
- NOTE – A region-wise packed picture may contain a *region-wise packing* of a *projected picture*.
- 3.138 region-wise packing:** A transformation, resizing, and relocation of *packed regions* of a *region-wise packed picture* to remap the *packed regions* to *projected regions* of a *projected picture*.
- 3.139 reserved:** A term that may be used to specify that some values of a particular *syntax element* are for future use by ITU-T | ISO/IEC and shall not be used in *bitstreams* conforming to this version of this Specification, but may be used in *bitstreams* conforming to future extensions of this Specification by ITU-T | ISO/IEC.
- 3.140 residual:** The decoded difference between a *prediction* of a sample or data element and its decoded value.
- 3.141 sample aspect ratio:** The ratio between the intended horizontal distance between the columns and the intended vertical distance between the rows of the *luma* sample array in a *picture*, which is specified for assisting the *display process* (not specified in this Specification) and expressed as $h:v$, where h is the horizontal width and v is the vertical height, in arbitrary units of spatial distance.
- 3.142 scalable-nested SEI message:** An SEI message that is contained in a scalable nesting SEI message.
- 3.143 scaling:** The process of multiplying *transform coefficient levels* by a factor, resulting in *transform coefficients*.
- 3.144 sequence parameter set (SPS):** A *syntax structure* containing *syntax elements* that apply to zero or more entire *CVSs* as determined by the content of a *syntax element* found in the *PPS* referred to by a *syntax element* found in each *slice segment header*.
- 3.145 shall:** A term used to express mandatory requirements for conformance to this Specification.
- NOTE – When used to express a mandatory constraint on the values of syntax elements or on the results obtained by operation of the specified decoding process, it is the responsibility of the encoder to ensure that the constraint is fulfilled. When used in reference to operations performed by the decoding process, any decoding process that produces identical cropped decoded pictures to those output from the decoding process described in this Specification conforms to the decoding process requirements of this Specification.
- 3.146 short-term reference picture:** A *picture* that is marked as "used for short-term reference".
- 3.147 short-term reference picture set:** The three RPS lists that may contain short-term reference pictures.
- 3.148 should:** A term used to refer to behaviour of an implementation that is encouraged to be followed under anticipated ordinary circumstances, but is not a mandatory requirement for conformance to this Specification.
- 3.149 slice:** An integer number of *CTUs* contained in one *independent slice segment* and all subsequent *dependent slice segments* (if any) that precede the next *independent slice segment* (if any) within the same *access unit*.
- 3.150 slice header:** The *slice segment header* of the *independent slice segment* that is a current *slice segment* or the most recent *independent slice segment* that precedes a current *dependent slice segment* in *decoding order*.
- 3.151 slice segment:** An integer number of *CTUs* ordered consecutively in the *tile scan* and contained in a single *NAL unit*.
- 3.152 slice segment header:** A part of a coded *slice segment* containing the data elements pertaining to the first or all *CTUs* represented in the *slice segment*.
- 3.153 source:** A term used to describe the video material or some of its attributes before encoding.
- 3.154 sphere coordinates:** The azimuth and elevation angles identifying a location of a point on a sphere.
- 3.155 sphere region:** A region on a sphere, specified either by four *great circles* or by two *azimuth circles* and two *elevation circles*, or such a region on a rotated sphere after applying yaw, pitch, and roll rotations.
- 3.156 start code prefix:** A unique sequence of three *bytes* equal to 0x000001 embedded in the *byte stream* as a prefix to each *NAL unit*.
- NOTE – The location of a start code prefix can be used by a decoder to identify the beginning of a new NAL unit and the end of a previous NAL unit. Emulation of start code prefixes is prevented within NAL units by the inclusion of emulation prevention bytes.
- 3.157 step-wise temporal sub-layer access (STSA) access unit:** An *access unit* in which the *coded picture* with *nuh_layer_id* equal to 0 is an *STSA picture*.

- 3.158 step-wise temporal sub-layer access (STSA) picture:** A *coded picture* for which each *VCL NAL unit* has *nal_unit_type* equal to STSA_R or STSA_N.
- NOTE – An STSA picture does not use pictures with the same TemporalId as the STSA picture for inter prediction reference. Pictures following an STSA picture in decoding order with the same TemporalId as the STSA picture do not use pictures prior to the STSA picture in decoding order with the same TemporalId as the STSA picture for inter prediction reference. An STSA picture enables up-switching, at the STSA picture, to the sub-layer containing the STSA picture, from the immediately lower sub-layer. STSA pictures must have TemporalId greater than 0.
- 3.159 string of data bits (SODB):** A sequence of some number of bits representing *syntax elements* present within a *raw byte sequence payload* prior to the *raw byte sequence payload stop bit*, where the left-most bit is considered to be the first and most significant bit, and the right-most bit is considered to be the last and least significant bit.
- 3.160 sub-bitstream extraction process:** A specified process by which *NAL units* in a *bitstream* that do not belong to a target set, determined by a target highest TemporalId and a target *layer identifier list*, are removed from the *bitstream*, with the output sub-bitstream consisting of the *NAL units* in the *bitstream* that belong to the target set.
- 3.161 sub-layer:** A temporal scalable layer of a temporal scalable *bitstream*, consisting of *VCL NAL units* with a particular value of the TemporalId variable and the associated *non-VCL NAL units*.
- 3.162 sub-layer non-reference (SLNR) picture:** A *picture* that contains samples that cannot be used for *inter prediction* in the *decoding process* of subsequent *pictures* of the same *sub-layer* in *decoding order*.
- NOTE – Samples of an SLNR picture may be used for inter prediction in the decoding process of subsequent pictures of higher sub-layers in decoding order.
- 3.163 sub-layer reference picture:** A *picture* that contains samples that may be used for *inter prediction* in the *decoding process* of subsequent *pictures* of the same *sub-layer* in *decoding order*.
- NOTE – Samples of a sub-layer reference picture may also be used for inter prediction in the decoding process of subsequent pictures of higher sub-layers in decoding order.
- 3.164 sub-layer representation:** A subset of the *bitstream* consisting of *NAL units* of a particular *sub-layer* and the lower *sub-layers*.
- 3.165 suffix SEI message:** An SEI message that is contained in a *suffix SEI NAL unit*.
- 3.166 suffix SEI NAL unit:** An *SEI NAL unit* that has *nal_unit_type* equal to SUFFIX_SEI_NUT.
- 3.167 supplemental enhancement information (SEI) NAL unit:** A *NAL unit* that has *nal_unit_type* equal to PREFIX_SEI_NUT or SUFFIX_SEI_NUT.
- 3.168 syntax element:** An element of data represented in the *bitstream*.
- 3.169 syntax structure:** Zero or more *syntax elements* present together in the *bitstream* in a specified order.
- 3.170 temporal sub-layer:** Same as *sub-layer*.
- 3.171 temporal sub-layer access (TSA) access unit:** An *access unit* in which the *coded picture* with *nuh_layer_id* equal to 0 is a *TSA picture*.
- 3.172 temporal sub-layer access (TSA) picture:** A *coded picture* for which each *VCL NAL unit* has *nal_unit_type* equal to TSA_R or TSA_N.
- NOTE – A TSA picture and pictures following the TSA picture in decoding order do not use pictures prior to the TSA picture in decoding order with TemporalId greater than or equal to that of the TSA picture for inter prediction reference. A TSA picture enables up-switching, at the TSA picture, to the sub-layer containing the TSA picture or any higher sub-layer, from the immediately lower sub-layer. TSA pictures must have TemporalId greater than 0.
- 3.173 tier:** A specified category of *level* constraints imposed on values of the *syntax elements* in the *bitstream*, where the *level* constraints are nested within a *tier* and a *decoder* conforming to a certain *tier* and *level* would be capable of decoding all *bitstreams* that conform to the same *tier* or the lower *tier* of that *level* or any *level* below it.
- 3.174 tile:** A rectangular region of *CTUs* within a particular *tile column* and a particular *tile row* in a *picture*.
- 3.175 tile column:** A rectangular region of *CTUs* having a height equal to the height of the *picture* and a width specified by *syntax elements* in the *picture parameter set*.
- 3.176 tile row:** A rectangular region of *CTUs* having a height specified by *syntax elements* in the *picture parameter set* and a width equal to the width of the *picture*.
- 3.177 tile scan:** A specific sequential ordering of *CTUs* partitioning a *picture* in which the *CTUs* are ordered consecutively in *CTU raster scan* in a *tile*, whereas *tiles* in a *picture* are ordered consecutively in a *raster scan* of the *tiles* of the *picture*.

- 3.178 tilt angle:** The angle indicating the amount of tilt of a *sphere region*, measured as the amount of rotation of a *sphere region* along the axis originating from the sphere origin passing through the centre point of the *sphere region*, where the angle value increases clockwise when looking from the origin towards the positive end of the axis.
- 3.179 trailing picture:** A non-IRAP *picture* that follows the *associated IRAP picture* in *output order*.
NOTE – Trailing pictures associated with an IRAP picture also follow the IRAP picture in decoding order. Pictures that follow the associated IRAP picture in output order and precede the associated IRAP picture in decoding order are not allowed.
- 3.180 transform:** A part of the *decoding process* by which a *block* of *transform coefficients* is converted to a *block* of spatial-domain values.
- 3.181 transform block:** A rectangular MxN *block* of samples resulting from a *transform* in the *decoding process*.
- 3.182 transform coefficient:** A scalar quantity, considered to be in a frequency domain, that is associated with a particular one-dimensional or two-dimensional *frequency index* in a *transform* in the *decoding process*.
- 3.183 transform coefficient level:** An integer quantity representing the value associated with a particular two-dimensional frequency index in the *decoding process* prior to *scaling* for computation of a *transform coefficient* value.
- 3.184 transform unit:** A *transform block* of *luma* samples of size 8x8, 16x16, or 32x32 or four *transform blocks* of *luma* samples of size 4x4, two corresponding *transform blocks* of *chroma* samples of a *picture* in 4:2:0 colour format; or a *transform block* of *luma* samples of size 8x8, 16x16, or 32x32, and four corresponding *transform blocks* of *chroma* samples, or four *transform blocks* of *luma* samples of size 4x4, and four corresponding *transform blocks* of *chroma* samples of a *picture* in 4:2:2 colour format; or a *transform block* of *luma* samples of size 4x4, 8x8, 16x16, or 32x32, and two corresponding *transform blocks* of *chroma* samples of a *picture* in 4:4:4 colour format that is not coded using three separate colour planes and *syntax structures* used to transform the *transform block* samples; or a *transform block* of *luma* samples of size 8x8, 16x16, or 32x32 or four *transform blocks* of *luma* samples of size 4x4 of a monochrome *picture* or a *picture* in 4:4:4 colour format that is coded using three separate colour planes; and the associated *syntax structures* used to transform the *transform block* samples.
- 3.185 tree:** A tree is a finite set of nodes with a unique root node.
- 3.186 universal unique identifier (UUID):** An identifier that is unique with respect to the space of all universal unique identifiers.
- 3.187 unspecified:** A term that may be used to specify some values of a particular *syntax element* to indicate that the values have no specified meaning in this Specification and will not have a specified meaning in the future as an integral part of future versions of this Specification.
- 3.188 video coding layer (VCL) NAL unit:** A collective term for *coded slice segment NAL units* and the subset of *NAL units* that have *reserved* values of *nal_unit_type* that are classified as VCL NAL units in this Specification.
- 3.189 video parameter set (VPS):** A *syntax structure* containing *syntax elements* that apply to zero or more entire *CVSs* as determined by the content of a *syntax element* found in the *SPS* referred to by a *syntax element* found in the *PPS* referred to by a *syntax element* found in each *slice segment header*.
- 3.190 viewport:** A region of *omnidirectional video* content suitable for display and viewing by the user.
- 3.191 z-scan order:** A specified sequential ordering of *blocks* partitioning a *picture*, where the order is identical to *CTB raster scan* of the *picture* when the *blocks* are of the same size as *CTBs*, and, when the *blocks* are of a smaller size than *CTBs*, i.e., *CTBs* are further partitioned into smaller *coding blocks*, the order traverses from *CTB* to *CTB* in *CTB raster scan* of the *picture*, and inside each *CTB*, which may be divided into *quadtrees* hierarchically to lower levels, the order traverses from *quadtree* to *quadtree* of a particular level in *quadtree-of-the-particular-level raster scan* of the *quadtree* of the immediately higher level.

4 Abbreviations and acronyms

For the purposes of this Recommendation | International Standard, the following abbreviations and acronyms apply:

ATSC	Advanced Television Systems Committee
B	Bi-predictive
BLA	Broken Link Access

BPB	Bitstream Partition Buffer
CABAC	Context-based Adaptive Binary Arithmetic Coding
CB	Coding Block
CBR	Constant Bit Rate
CIE	International Commission on Illumination (Commission Internationale de l'Eclairage)
CLVS	Coded Layer-wise Video Sequence
CPB	Coded Picture Buffer
CRA	Clean Random Access
CRC	Cyclic Redundancy Check
CTB	Coding Tree Block
CTU	Coding Tree Unit
CU	Coding Unit
CVS	Coded Video Sequence
CVSG	Coded Video Sequence Group
DCT	Discrete Cosine Transform
DPB	Decoded Picture Buffer
DRAP	Dependent Random Access Point
DUT	Decoder Under Test
EG	Exponential-Golomb
EGk	k-th order Exponential-Golomb
FCC	Federal Communications Commission (of the United States)
FIFO	First-In, First-Out
FIR	Finite Impulse Response
FL	Fixed-Length
GBR	Green, Blue and Red
GDR	Gradual Decoding Refresh
HRD	Hypothetical Reference Decoder
HSS	Hypothetical Stream Scheduler
I	Intra
IDCT	Inverse Discrete Cosine Transformation
IDR	Instantaneous Decoding Refresh
INBLD	Independent Non-Base Layer Decoding
IRAP	Intra Random Access Point
LPS	Least Probable Symbol
LSB	Least Significant Bit
MCTS	Motion-Constrained Tile Set
MAC	Multiplexed Analogue Components
MPS	Most Probable Symbol
MSB	Most Significant Bit
MVP	Motion Vector Prediction

NAL	Network Abstraction Layer
NTSC	National Television System Committee (of the United States)
OLS	Output Layer Set
P	Predictive
PAL	Phase Alternating Line
PB	Prediction Block
PCM	Pulse Code Modulation
POC	Picture Order Count
PPS	Picture Parameter Set
PU	Prediction Unit
QP	Quantization Parameter
RADL	Random Access Decodable Leading (Picture)
RASL	Random Access Skipped Leading (Picture)
RBSP	Raw Byte Sequence Payload
RGB	Same as GBR
RPS	Reference Picture Set
SAO	Sample Adaptive Offset
SAR	Sample Aspect Ratio
SECAM	Sequential colour with memory (Séquentiel Couleur avec Mémoire)
SEI	Supplemental Enhancement Information
SLNR	Sub-Layer Non-Reference (Picture)
SMPTE	Society of Motion Picture and Television Engineers
SODB	String Of Data Bits
SPS	Sequence Parameter Set
STSA	Step-wise Temporal Sub-layer Access
TB	Transform Block
TR	Truncated Rice
TSA	Temporal Sub-layer Access
TU	Transform Unit
UCS	Universal Coded Character Set
UTF	UCS Transmission Format
UUID	Universal Unique Identifier
VBR	Variable Bit Rate
VCL	Video Coding Layer
VPS	Video Parameter Set
VUI	Video Usability Information

5 Conventions

5.1 General

NOTE – The mathematical operators used in this Specification are similar to those used in the C programming language. However, the results of integer division and arithmetic shift operations are defined more precisely, and additional operations are defined, such as exponentiation and real-valued division. Numbering and counting conventions generally begin from 0, e.g., "the first" is equivalent to the 0-th, "the second" is equivalent to the 1-th, etc.

5.2 Arithmetic operators

The following arithmetic operators are defined as follows:

+	Addition
–	Subtraction (as a two-argument operator) or negation (as a unary prefix operator)
*	Multiplication, including matrix multiplication
x^y	Exponentiation. Specifies x to the power of y . In other contexts, such notation is used for superscripting not intended for interpretation as exponentiation.
/	Integer division with truncation of the result toward zero. For example, $7 / 4$ and $-7 / -4$ are truncated to 1 and $-7 / 4$ and $7 / -4$ are truncated to -1 .
÷	Used to denote division in mathematical equations where no truncation or rounding is intended.
$\frac{x}{y}$	Used to denote division in mathematical equations where no truncation or rounding is intended.
$\sum_{i=x}^y$	The summation of $f(i)$ with i taking all integer values from x up to and including y .
$x \% y$	Modulus. Remainder of x divided by y , defined only for integers x and y with $x \geq 0$ and $y > 0$.

5.3 Logical operators

The following logical operators are defined as follows:

$x \ \&\& \ y$	Boolean logical "and" of x and y
$x \ \ y$	Boolean logical "or" of x and y
!	Boolean logical "not"
$x ? y : z$	If x is TRUE or not equal to 0, evaluates to the value of y ; otherwise, evaluates to the value of z .

5.4 Relational operators

The following relational operators are defined as follows:

>	Greater than
>=	Greater than or equal to
<	Less than
<=	Less than or equal to
==	Equal to
!=	Not equal to

When a relational operator is applied to a syntax element or variable that has been assigned the value "na" (not applicable), the value "na" is treated as a distinct value for the syntax element or variable. The value "na" is considered not to be equal to any other value.

5.5 Bit-wise operators

The following bit-wise operators are defined as follows:

&	Bit-wise "and". When operating on integer arguments, operates on a two's complement representation of the integer value. When operating on a binary argument that contains fewer bits than another argument, the shorter argument is extended by adding more significant bits equal to 0.
---	---

	Bit-wise "or". When operating on integer arguments, operates on a two's complement representation of the integer value. When operating on a binary argument that contains fewer bits than another argument, the shorter argument is extended by adding more significant bits equal to 0.
^	Bit-wise "exclusive or". When operating on integer arguments, operates on a two's complement representation of the integer value. When operating on a binary argument that contains fewer bits than another argument, the shorter argument is extended by adding more significant bits equal to 0.
x >> y	Arithmetic right shift of a two's complement integer representation of x by y binary digits. This function is defined only for non-negative integer values of y. Bits shifted into the most significant bits (MSBs) as a result of the right shift have a value equal to the MSB of x prior to the shift operation.
x << y	Arithmetic left shift of a two's complement integer representation of x by y binary digits. This function is defined only for non-negative integer values of y. Bits shifted into the least significant bits (LSBs) as a result of the left shift have a value equal to 0.

5.6 Assignment operators

The following arithmetic operators are defined as follows:

=	Assignment operator
++	Increment, i.e., $x++$ is equivalent to $x = x + 1$; when used in an array index, evaluates to the value of the variable prior to the increment operation.
--	Decrement, i.e., $x--$ is equivalent to $x = x - 1$; when used in an array index, evaluates to the value of the variable prior to the decrement operation.
+=	Increment by amount specified, i.e., $x += 3$ is equivalent to $x = x + 3$, and $x += (-3)$ is equivalent to $x = x + (-3)$.
-=	Decrement by amount specified, i.e., $x -= 3$ is equivalent to $x = x - 3$, and $x -= (-3)$ is equivalent to $x = x - (-3)$.

5.7 Range notation

The following notation is used to specify a range of values:

$x = y..z$ x takes on integer values starting from y to z, inclusive, with x, y, and z being integer numbers and z being greater than or equal to y.

5.8 Mathematical functions

The following mathematical functions are defined:

$$\text{Abs}(x) = \begin{cases} x & ; \quad x \geq 0 \\ -x & ; \quad x < 0 \end{cases} \quad (5-1)$$

$\text{Asin}(x)$ the trigonometric inverse sine function, operating on an argument x that is in the range of -1.0 to 1.0 , inclusive, with an output value in the range of $-\pi/2$ to $\pi/2$, inclusive, in units of radians
(5-2)

$\text{Atan}(x)$ the trigonometric inverse tangent function, operating on an argument x, with an output value in the range of $-\pi/2$ to $\pi/2$, inclusive, in units of radians
(5-3)

$$\text{Atan2}(y, x) = \begin{cases} \text{Atan}\left(\frac{y}{x}\right) & ; \quad x > 0 \\ \text{Atan}\left(\frac{y}{x}\right) + \pi & ; \quad x < 0 \ \&\& \ y \geq 0 \\ \text{Atan}\left(\frac{y}{x}\right) - \pi & ; \quad x < 0 \ \&\& \ y < 0 \\ +\frac{\pi}{2} & ; \quad x == 0 \ \&\& \ y \geq 0 \\ -\frac{\pi}{2} & ; \quad \text{otherwise} \end{cases} \quad (5-4)$$

Ceil(x) the smallest integer greater than or equal to x. (5-5)

Clip1_Y(x) = Clip3(0, (1 << BitDepth_Y) – 1, x)
(5-6)

Clip1_C(x) = Clip3(0, (1 << BitDepth_C) – 1, x)
(5-7)

$$\text{Clip3}(x, y, z) = \begin{cases} x & ; \quad z < x \\ y & ; \quad z > y \\ z & ; \quad \text{otherwise} \end{cases} \quad (5-8)$$

Cos(x) the trigonometric cosine function operating on an argument x in units of radians. (5-9)

Floor(x) the largest integer less than or equal to x.
(5-10)

$$\text{GetCurrMsb}(a, b, c, d) = \begin{cases} c + d & ; \quad b - a \geq d / 2 \\ c - d & ; \quad a - b \geq d / 2 \\ c & ; \quad \text{otherwise} \end{cases} \quad (5-11)$$

Ln(x) the natural logarithm of x (the base-e logarithm, where e is the natural logarithm base constant 2.718 281 828...). (5-12)

Log2(x) the base-2 logarithm of x. (5-13)

Log10(x) the base-10 logarithm of x. (5-14)

$$\text{Min}(x, y) = \begin{cases} x & ; \quad x \leq y \\ y & ; \quad x > y \end{cases} \quad (5-15)$$

$$\text{Max}(x, y) = \begin{cases} x & ; \quad x \geq y \\ y & ; \quad x < y \end{cases} \quad (5-16)$$

Round(x) = Sign(x) * Floor(Abs(x) + 0.5) (5-17)

$$\text{Sign}(x) = \begin{cases} 1 & ; \quad x > 0 \\ 0 & ; \quad x == 0 \\ -1 & ; \quad x < 0 \end{cases} \quad (5-18)$$

Sin(x) the trigonometric sine function operating on an argument x in units of radians (5-19)

Sqrt(x) the square root of x (5-20)

Swap(x, y) = (y, x) (5-21)

Tan(x) the trigonometric tangent function operating on an argument x in units of radians (5-22)

5.9 Order of operation precedence

When order of precedence in an expression is not indicated explicitly by use of parentheses, the following rules apply:

- Operations of a higher precedence are evaluated before any operation of a lower precedence.
- Operations of the same precedence are evaluated sequentially from left to right.

Table 5-1 specifies the precedence of operations from highest to lowest; a higher position in the table indicates a higher precedence.

NOTE – For those operators that are also used in the C programming language, the order of precedence used in this Specification is the same as used in the C programming language.

Table 5-1 – Operation precedence from highest (at top of table) to lowest (at bottom of table)

operations (with operands x, y, and z)
"x++", "x--"
"!x", "-x" (as a unary prefix operator)
x^y
"x * y", "x / y", "x ÷ y", " $\frac{x}{y}$ ", "x % y"
"x + y", "x - y" (as a two-argument operator), " $\sum_{i=x}^y f(i)$ "
"x << y", "x >> y"
"x < y", "x <= y", "x > y", "x >= y"
"x == y", "x != y"
"x & y"
"x y"
"x && y"
"x y"
"x ? y : z"
"x.y"
"x = y", "x += y", "x -= y"

5.10 Variables, syntax elements and tables

Syntax elements in the bitstream are represented in **bold** type. Each syntax element is described by its name (all lower case letters with underscore characters), and one descriptor for its method of coded representation. The decoding process behaves according to the value of the syntax element and to the values of previously decoded syntax elements. When a value of a syntax element is used in the syntax tables or the text, it appears in regular (i.e., not bold) type.

In some cases the syntax tables may use the values of other variables derived from syntax elements values. Such variables appear in the syntax tables, or text, named by a mixture of lower case and upper case letters and without any underscore characters. Variables starting with an upper case letter are derived for the decoding of the current syntax structure and all depending syntax structures. Variables starting with an upper case letter may be used in the decoding process for later syntax structures without mentioning the originating syntax structure of the variable. Variables starting with a lower case letter are only used within the clause in which they are derived.

In some cases, "mnemonic" names for syntax element values or variable values are used interchangeably with their numerical values. Sometimes "mnemonic" names are used without any associated numerical values. The association of values and names is specified in the text. The names are constructed from one or more groups of letters separated by an underscore character. Each group starts with an upper case letter and may contain more upper case letters.

NOTE – The syntax is described in a manner that closely follows the C-language syntactic constructs.

Functions that specify properties of the current position in the bitstream are referred to as syntax functions. These functions are specified in clause 7.2 and assume the existence of a bitstream pointer with an indication of the position of the next bit to be read by the decoding process from the bitstream. Syntax functions are described by their names, which are constructed as syntax element names and end with left and right parentheses including zero or more variable names (for definition) or values (for usage), separated by commas (if more than one variable).

Functions that are not syntax functions (including mathematical functions specified in clause 5.8) are described by their names, which start with an upper case letter, contain a mixture of lower and upper case letters without any underscore character, and end with left and right parentheses including zero or more variable names (for definition) or values (for usage) separated by commas (if more than one variable).

A one-dimensional array is referred to as a list. A two-dimensional array is referred to as a matrix. Arrays can either be syntax elements or variables. Subscripts or square parentheses are used for the indexing of arrays. In reference to a visual depiction of a matrix, the first subscript is used as a row (vertical) index and the second subscript is used as a column (horizontal) index. The indexing order is reversed when using square parentheses rather than subscripts for indexing.

Thus, an element of a matrix s at horizontal position x and vertical position y may be denoted either as $s[x][y]$ or as s_{yx} . A single column of a matrix may be referred to as a list and denoted by omission of the row index. Thus, the column of a matrix s at horizontal position x may be referred to as the list $s[x]$.

A specification of values of the entries in rows and columns of an array may be denoted by $\{ \{ \dots \} \{ \dots \} \}$, where each inner pair of brackets specifies the values of the elements within a row in increasing column order and the rows are ordered in increasing row order. Thus, setting a matrix s equal to $\{ \{ 1 \ 6 \} \{ 4 \ 9 \} \}$ specifies that $s[0][0]$ is set equal to 1, $s[1][0]$ is set equal to 6, $s[0][1]$ is set equal to 4, and $s[1][1]$ is set equal to 9.

Binary notation is indicated by enclosing the string of bit values by single quote marks. For example, '01000001' represents an eight-bit string having only its second and its last bits (counted from the most to the least significant bit) equal to 1.

Hexadecimal notation, indicated by prefixing the hexadecimal number by "0x", may be used instead of binary notation when the number of bits is an integer multiple of 4. For example, 0x41 represents an eight-bit string having only its second and its last bits (counted from the most to the least significant bit) equal to 1.

Numerical values not enclosed in single quotes and not prefixed by "0x" are decimal values.

A value equal to 0 represents a FALSE condition in a test statement. The value TRUE is represented by any value different from zero.

5.11 Text description of logical operations

In the text, a statement of logical operations as would be described mathematically in the following form:

```
if( condition 0 )
    statement 0
else if( condition 1 )
    statement 1
...
else /* informative remark on remaining condition */
    statement n
```

may be described in the following manner:

- ... as follows / ... the following applies:
- If condition 0, statement 0
- Otherwise, if condition 1, statement 1
- ...
- Otherwise (informative remark on remaining condition), statement n

Each "If ... Otherwise, if ... Otherwise, ..." statement in the text is introduced with "... as follows" or "... the following applies" immediately followed by "If ... ". The last condition of the "If ... Otherwise, if ... Otherwise, ..." is always an "Otherwise, ...". Interleaved "If ... Otherwise, if ... Otherwise, ..." statements can be identified by matching "... as follows" or "... the following applies" with the ending "Otherwise, ...".

In the text, a statement of logical operations as would be described mathematically in the following form:

```
if( condition 0a && condition 0b )
    statement 0
else if( condition 1a || condition 1b )
    statement 1
...
else
    statement n
```

may be described in the following manner:

- ... as follows / ... the following applies:
- If all of the following conditions are true, statement 0:
 - condition 0a
 - condition 0b
- Otherwise, if one or more of the following conditions are true, statement 1:

- condition 1a
- condition 1b
- ...
- Otherwise, statement n

In the text, a statement of logical operations as would be described mathematically in the following form:

```

if( condition 0 )
    statement 0
if( condition 1 )
    statement 1

```

may be described in the following manner:

```

When condition 0, statement 0
When condition 1, statement 1

```

5.12 Processes

Processes are used to describe the decoding of syntax elements. A process has a separate specification and invoking. All syntax elements and upper case variables that pertain to the current syntax structure and depending syntax structures are available in the process specification and invoking. A process specification may also have a lower case variable explicitly specified as input. Each process specification has explicitly specified an output. The output is a variable that can either be an upper case variable or a lower case variable.

When invoking a process, the assignment of variables is specified as follows:

- If the variables at the invoking and the process specification do not have the same name, the variables are explicitly assigned to lower case input or output variables of the process specification.
- Otherwise (the variables at the invoking and the process specification have the same name), assignment is implied.

In the specification of a process, a specific coding block may be referred to by the variable name having a value equal to the address of the specific coding block.

6 Bitstream and picture formats, partitionings, scanning processes and neighbouring relationships

6.1 Bitstream formats

This clause specifies the relationship between the network abstraction layer (NAL) unit stream and byte stream, either of which are referred to as the bitstream.

The bitstream can be in one of two formats: the NAL unit stream format or the byte stream format. The NAL unit stream format is conceptually the more "basic" type. It consists of a sequence of syntax structures called NAL units. This sequence is ordered in decoding order. There are constraints imposed on the decoding order (and contents) of the NAL units in the NAL unit stream.

The byte stream format can be constructed from the NAL unit stream format by ordering the NAL units in decoding order and prefixing each NAL unit with a start code prefix and zero or more zero-valued bytes to form a stream of bytes. The NAL unit stream format can be extracted from the byte stream format by searching for the location of the unique start code prefix pattern within this stream of bytes. Methods of framing the NAL units in a manner other than use of the byte stream format are outside the scope of this Specification. The byte stream format is specified in Annex B.

6.2 Source, decoded and output picture formats

This clause specifies the relationship between source and decoded pictures that is given via the bitstream.

The video source that is represented by the bitstream is a sequence of pictures in decoding order.

The source and decoded pictures are each comprised of one or more sample arrays:

- Luma (Y) only (monochrome).
- Luma and two chroma (YCbCr or YCgCo).

- Green, blue, and red (GBR, also known as RGB).
- Arrays representing other unspecified monochrome or tri-stimulus colour samplings (for example, YZX, also known as XYZ).

For convenience of notation and terminology in this Specification, the variables and terms associated with these arrays are referred to as luma (or L or Y) and chroma, where the two chroma arrays are referred to as Cb and Cr; regardless of the actual colour representation method in use. The actual colour representation method in use can be indicated in syntax that is specified in Annex E.

The variables SubWidthC and SubHeightC are specified in Table 6-1, depending on the chroma format sampling structure, which is specified through chroma_format_idc and separate_colour_plane_flag. Other values of chroma_format_idc, SubWidthC and SubHeightC may be specified in the future by ITU-T | ISO/IEC.

Table 6-1 – SubWidthC and SubHeightC values derived from chroma_format_idc and separate_colour_plane_flag

chroma_format_idc	separate_colour_plane_flag	Chroma format	SubWidthC	SubHeightC
0	0	Monochrome	1	1
1	0	4:2:0	2	2
2	0	4:2:2	2	1
3	0	4:4:4	1	1
3	1	4:4:4	1	1

In monochrome sampling there is only one sample array, which is nominally considered the luma array.

In 4:2:0 sampling, each of the two chroma arrays has half the height and half the width of the luma array.

In 4:2:2 sampling, each of the two chroma arrays has the same height and half the width of the luma array.

In 4:4:4 sampling, depending on the value of separate_colour_plane_flag, the following applies:

- If separate_colour_plane_flag is equal to 0, each of the two chroma arrays has the same height and width as the luma array.
- Otherwise (separate_colour_plane_flag is equal to 1), the three colour planes are separately processed as monochrome sampled pictures.

The number of bits necessary for the representation of each of the samples in the luma and chroma arrays in a video sequence is in the range of 8 to 16, inclusive, and the number of bits used in the luma array may differ from the number of bits used in the chroma arrays.

When the value of chroma_format_idc is equal to 1, the nominal vertical and horizontal relative locations of luma and chroma samples in pictures are shown in Figure 6-1. Alternative chroma sample relative locations may be indicated in video usability information (see Annex E).

Figure 6-1 – Nominal vertical and horizontal locations of 4:2:0 luma and chroma samples in a picture

When the value of chroma_format_idc is equal to 2, the chroma samples are co-sited with the corresponding luma samples and the nominal locations in a picture are as shown in Figure 6-2.

Figure 6-2 – Nominal vertical and horizontal locations of 4:2:2 luma and chroma samples in a picture

When the value of chroma_format_idc is equal to 3, all array samples are co-sited for all cases of pictures and the nominal locations in a picture are as shown in Figure 6-3.

Figure 6-3 – Nominal vertical and horizontal locations of 4:4:4 luma and chroma samples in a picture

6.3 Partitioning of pictures, slices, slice segments, tiles, CTUs and CTBs

6.3.1 Partitioning of pictures into slices, slice segments and tiles

This clause specifies how a picture is partitioned into slices, slice segments and tiles. Pictures are divided into slices and tiles. A slice is a sequence of one or more slice segments starting with an independent slice segment and containing all subsequent dependent slice segments (if any) that precede the next independent slice segment (if any) within the same picture. A slice segment is a sequence of CTUs. Likewise, a tile is a sequence of CTUs.

For example, a picture may be divided into two slices as shown in Figure 6-4. In this example, the first slice is composed of an independent slice segment containing 4 CTUs, a dependent slice segment containing 32 CTUs and another dependent slice segment containing 24 CTUs; and the second slice consists of a single independent slice segment containing the remaining 39 CTUs of the picture.

As another example, a picture may be divided into two tiles separated by a vertical tile boundary as shown in Figure 6-5. The left side of the figure illustrates a case in which the picture only contains one slice, starting with an independent slice segment and followed by four dependent slice segments. The right side of the figure illustrates an alternative case in which the picture contains two slices in the first tile and one slice in the second tile.

Unlike slices, tiles are always rectangular. A tile always contains an integer number of CTUs, and may consist of CTUs contained in more than one slice. Similarly, a slice may consist of CTUs contained in more than one tile.

One or both of the following conditions shall be fulfilled for each slice and tile:

- All CTUs in a slice belong to the same tile.

- All CTUs in a tile belong to the same slice.

NOTE 1 – Within the same picture, there may be both slices that contain multiple tiles and tiles that contain multiple slices.

One or both of the following conditions shall be fulfilled for each slice segment and tile:

- All CTUs in a slice segment belong to the same tile.
- All CTUs in a tile belong to the same slice segment.

When a picture is coded using three separate colour planes (separate_colour_plane_flag is equal to 1), a slice contains only CTBs of one colour component being identified by the corresponding value of colour_plane_id, and each colour component array of a picture consists of slices having the same colour_plane_id value. Coded slices with different values of colour_plane_id within a picture may be interleaved with each other under the constraint that for each value of colour_plane_id, the coded slice segment NAL units with that value of colour_plane_id shall be in the order of increasing CTB address in tile scan order for the first CTB of each coded slice segment NAL unit.

NOTE 2 – When separate_colour_plane_flag is equal to 0, each CTB of a picture is contained in exactly one slice. When separate_colour_plane_flag is equal to 1, each CTB of a colour component is contained in exactly one slice (i.e., information for each CTB of a picture is present in exactly three slices and these three slices have different values of colour_plane_id).

Figure 6-4 – A picture with 11 by 9 luma CTBs that is partitioned into two slices, the first of which is partitioned into three slice segments (informative)

Figure 6-5 – A picture with 11 by 9 luma CTBs that is partitioned into two tiles and one slice (left) or is partitioned into two tiles and three slices (right) (informative)

6.3.2 Block and quadtree structures

The samples are processed in units of CTBs. The array size for each luma CTB in both width and height is CtbSizeY in units of samples. The width and height of the array for each chroma CTB are CtbWidthC and CtbHeightC, respectively, in units of samples.

Each CTB is assigned a partition signalling to identify the block sizes for intra or inter prediction and for transform coding. The partitioning is a recursive quadtree partitioning. The root of the quadtree is associated with the CTB. The quadtree is split until a leaf is reached, which is referred to as the coding block. When the component width is not an integer number of the CTB size, the CTBs at the right component boundary are incomplete. When the component height is not an integer multiple of the CTB size, the CTBs at the bottom component boundary are incomplete.

The coding block is the root node of two trees, the prediction tree and the transform tree. The prediction tree specifies the position and size of prediction blocks. The transform tree specifies the position and size of transform blocks. The splitting information for luma and chroma is identical for the prediction tree and may or may not be identical for the transform tree.

The blocks and associated syntax structures are grouped into "unit" structures as follows:

- One prediction block (monochrome picture or `separate_colour_plane_flag` is equal to 1) or three prediction blocks (luma and chroma components of a picture in 4:2:0 or 4:4:4 colour format) or five prediction blocks (luma and chroma components of a picture in 4:2:2 colour format) and the associated prediction syntax structures units are associated with a prediction unit.
- One transform block (monochrome picture or `separate_colour_plane_flag` is equal to 1) or three transform blocks (luma and chroma components of a picture in 4:2:0 or 4:4:4 colour format) or five transform blocks (luma and chroma components of a picture in 4:2:2 colour format) and the associated transform syntax structures units are associated with a transform unit.
- One coding block (monochrome picture or `separate_colour_plane_flag` is equal to 1) or three coding blocks (luma and chroma), the associated coding syntax structures and the associated prediction and transform units are associated with a coding unit.
- One CTB (monochrome picture or `separate_colour_plane_flag` is equal to 1) or three CTBs (luma and chroma), the associated coding tree syntax structures and the associated coding units are associated with a CTU.

6.3.3 Spatial or component-wise partitionings

The following divisions of processing elements of this Specification form spatial or component-wise partitionings:

- The division of each picture into components
- The division of each component into CTBs
- The division of each picture into tile columns
- The division of each picture into tile rows
- The division of each tile column into tiles
- The division of each tile row into tiles
- The division of each tile into CTUs
- The division of each picture into slices
- The division of each slice into slice segments
- The division of each slice segment into CTUs
- The division of each CTU into CTBs
- The division of each CTB into coding blocks, except that the CTBs are incomplete at the right component boundary when the component width is not an integer multiple of the CTB size and the CTBs are incomplete at the bottom component boundary when the component height is not an integer multiple of the CTB size
- The division of each CTU into coding units, except that the CTUs are incomplete at the right picture boundary when the picture width in luma samples is not an integer multiple of the luma CTB size and the CTUs are incomplete at the bottom picture boundary when the picture height in luma samples is not an integer multiple of the luma CTB size
- The division of each coding unit into prediction units
- The division of each coding unit into transform units
- The division of each coding unit into coding blocks
- The division of each coding block into prediction blocks
- The division of each coding block into transform blocks
- The division of each prediction unit into prediction blocks
- The division of each transform unit into transform blocks.

6.4 Availability processes

6.4.1 Derivation process for z-scan order block availability

Inputs to this process are:

- The luma location (x_{Curr} , y_{Curr}) of the top-left sample of the current block relative to the top-left luma sample of the current picture
- The luma location (x_{NbY} , y_{NbY}) covered by a neighbouring block relative to the top-left luma sample of the current picture.

Output of this process is the availability of the neighbouring block covering the location (x_{NbY} , y_{NbY}), denoted as $availableN$.

The minimum luma block address in z-scan order $minBlockAddrCurr$ of the current block is derived as follows:

$$minBlockAddrCurr = MinTbAddrZs[x_{Curr} \gg MinTbLog2SizeY][y_{Curr} \gg MinTbLog2SizeY] \quad (6-1)$$

The minimum luma block address in z-scan order $minBlockAddrN$ of the neighbouring block covering the location (x_{NbY} , y_{NbY}) is derived as follows:

- If one or more of the following conditions are true, $minBlockAddrN$ is set equal to -1 :
 - x_{NbY} is less than 0
 - y_{NbY} is less than 0
 - x_{NbY} is greater than or equal to $pic_width_in_luma_samples$
 - y_{NbY} is greater than or equal to $pic_height_in_luma_samples$
- Otherwise (x_{NbY} and y_{NbY} are inside the picture boundaries),

$$minBlockAddrN = MinTbAddrZs[x_{NbY} \gg MinTbLog2SizeY][y_{NbY} \gg MinTbLog2SizeY] \quad (6-2)$$

The neighbouring block availability $availableN$ is derived as follows:

- If one or more of the following conditions are true, $availableN$ is set equal to FALSE:
 - $minBlockAddrN$ is less than 0,
 - $minBlockAddrN$ is greater than $minBlockAddrCurr$,
 - the variable $SliceAddrRs$ associated with the slice segment containing the neighbouring block with the minimum luma block address $minBlockAddrN$ differs in value from the variable $SliceAddrRs$ associated with the slice segment containing the current block with the minimum luma block address $minBlockAddrCurr$.
 - the neighbouring block with the minimum luma block address $minBlockAddrN$ is contained in a different tile than the current block with the minimum luma block address $minBlockAddrCurr$.
- Otherwise, $availableN$ is set equal to TRUE.

6.4.2 Derivation process for prediction block availability

Inputs to this process are:

- the luma location (x_{Cb} , y_{Cb}) of the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a variable $nCbS$ specifying the size of the current luma coding block,
- the luma location (x_{Pb} , y_{Pb}) of the top-left sample of the current luma prediction block relative to the top-left luma sample of the current picture,
- two variables $nPbW$ and $nPbH$ specifying the width and the height of the current luma prediction block,
- a variable $partIdx$ specifying the partition index of the current prediction unit within the current coding unit,
- the luma location (x_{NbY} , y_{NbY}) covered by a neighbouring prediction block relative to the top-left luma sample of the current picture.

Output of this process is the availability of the neighbouring prediction block covering the location (x_{NbY} , y_{NbY}), denoted as $availableN$ is derived as follows:

The variable $sameCb$ identifies whether the current luma prediction block and the neighbouring luma prediction block cover the same luma coding block, and is derived as follows:

- If all of the following conditions are true, $sameCb$ is set equal to TRUE:
 - x_{Cb} is less than or equal than x_{NbY} ,
 - y_{Cb} is less than or equal than y_{NbY} ,
 - $(x_{Cb} + n_{CbS})$ is greater than x_{NbY} ,
 - $(y_{Cb} + n_{CbS})$ is greater than y_{NbY} .
- Otherwise, $sameCb$ is set equal to FALSE.

The neighbouring prediction block availability $availableN$ is derived as follows:

- If $sameCb$ is equal to FALSE, the derivation process for z-scan order block availability as specified in clause 6.4.1 is invoked with (x_{Curr} , y_{Curr}) set equal to (x_{Pb} , y_{Pb}) and the luma location (x_{NbY} , y_{NbY}) as inputs, and the output is assigned to $availableN$.
- Otherwise, if all of the following conditions are true, $availableN$ is set equal to FALSE:
 - $(n_{PbW} << 1)$ is equal to n_{CbS} ,
 - $(n_{PbH} << 1)$ is equal to n_{CbS} ,
 - $partIdx$ is equal to 1,
 - $(y_{Cb} + n_{PbH})$ is less than or equal to y_{NbY} ,
 - $(x_{Cb} + n_{PbW})$ is greater than x_{NbY} .
- Otherwise, $availableN$ is set equal to TRUE.

When $availableN$ is equal to TRUE and $CuPredMode[x_{NbY}][y_{NbY}]$ is equal to $MODE_INTRA$, $availableN$ is set equal to FALSE.

6.5 Scanning processes

6.5.1 CTB raster and tile scanning conversion process

The list $colWidth[i]$ for i ranging from 0 to $num_tile_columns_minus1$, inclusive, specifying the width of the i -th tile column in units of CTBs, is derived as follows:

```

if( uniform_spacing_flag )
    for( i = 0; i <= num_tile_columns_minus1; i++ )
        colWidth[ i ] = ( ( i + 1 ) * PicWidthInCtbsY ) / ( num_tile_columns_minus1 + 1 ) -
                        ( i * PicWidthInCtbsY ) / ( num_tile_columns_minus1 + 1 )
else {
    colWidth[ num_tile_columns_minus1 ] = PicWidthInCtbsY
    for( i = 0; i < num_tile_columns_minus1; i++ ) {
        colWidth[ i ] = column_width_minus1[ i ] + 1
        colWidth[ num_tile_columns_minus1 ] -= colWidth[ i ]
    }
}

```

(6-3)

The list $rowHeight[j]$ for j ranging from 0 to $num_tile_rows_minus1$, inclusive, specifying the height of the j -th tile row in units of CTBs, is derived as follows:

```

if( uniform_spacing_flag )
    for( j = 0; j <= num_tile_rows_minus1; j++ )

) * colWidth[ tileX ] + tbX - colBd[ tileX ]
}
(6-7)

```

The list CtbAddrTsToRs[ctbAddrTs] for ctbAddrTs ranging from 0 to PicSizeInCtbsY - 1, inclusive, specifying the conversion from a CTB address in tile scan to a CTB address in CTB raster scan of a picture, is derived as follows:

```

for( ctbAddrRs = 0; ctbAddrRs < PicSizeInCtbsY; ctbAddrRs++ )
    CtbAddrTsToRs[ CtbAddrRsToTs[ ctbAddrRs ] ] = ctbAddrRs
(6-8)

```

The list TileId[ctbAddrTs] for ctbAddrTs ranging from 0 to PicSizeInCtbsY - 1, inclusive, specifying the conversion from a CTB address in tile scan to a tile ID, is derived as follows:

```

for( j = 0, tileIdx = 0; j <= num_tile_rows_minus1; j++ )
    for( i = 0; i <= num_tile_columns_minus1; i++, tileIdx++ )
        for( y = rowBd[ j ]; y < rowBd[ j + 1 ]; y++ )
            for( x = colBd[ i ]; x < colBd[ i + 1 ]; x++ )
                TileId[ CtbAddrRsToTs[ y * PicWidthInCtbsY + x ] ] = tileIdx
(6-9)

```

The values of ColumnWidthInLumaSamples[i], specifying the width of the i-th tile column in units of luma samples, are set equal to colWidth[i] << CtbLog2SizeY for i ranging from 0 to num_tile_columns_minus1, inclusive.

The values of `RowHeightInLumaSamples[j]`, specifying the height of the j -th tile row in units of luma samples, are set equal to `rowHeight[j] << CtbLog2SizeY` for j ranging from 0 to `num_tile_rows_minus1`, inclusive.

6.5.2 Z-scan order array initialization process

The array `MinTbAddrZs` with elements `MinTbAddrZs[x][y]` for x ranging from 0 to $(\text{PicWidthInCtbsY} \ll (\text{CtbLog2SizeY} - \text{MinTbLog2SizeY})) - 1$, inclusive, and y ranging from 0 to $(\text{PicHeightInCtbsY} \ll (\text{CtbLog2SizeY} - \text{MinTbLog2SizeY})) - 1$, specifying the conversion from a location (x, y) in units of minimum blocks to a minimum block address in z-scan order, inclusive, is derived as follows:

```

for( y = 0; y < ( PicHeightInCtbsY << ( CtbLog2SizeY - MinTbLog2SizeY ) ); y++ )
  for( x = 0; x < ( PicWidthInCtbsY << ( CtbLog2SizeY - MinTbLog2SizeY ) ); x++ ) {
    tbX = ( x << MinTbLog2SizeY ) >> CtbLog2SizeY
    tbY = ( y << MinTbLog2SizeY ) >> CtbLog2SizeY
    ctbAddrRs = PicWidthInCtbsY * tbY + tbX
    MinTbAddrZs[ x ][ y ] = CtbAddrRsToTs[ ctbAddrRs ] <<
      ( ( CtbLog2SizeY - MinTbLog2SizeY ) * 2 )
    for( i = 0, p = 0; i < ( CtbLog2SizeY - MinTbLog2SizeY ); i++ ) {
      m = 1 << i
      p += ( m & x ? m * m : 0 ) + ( m & y ? 2 * m * m : 0 )
    }
    MinTbAddrZs[ x ][ y ] += p
  }

```

(6-10)

6.5.3 Up-right diagonal scan order array initialization process

Input to this process is a block size `blkSize`.

Output of this process is the array `diagScan[sPos][sComp]`. The array index `sPos` specify the scan position ranging from 0 to $(\text{blkSize} * \text{blkSize}) - 1$. The array index `sComp` equal to 0 specifies the horizontal component and the array index `sComp` equal to 1 specifies the vertical component. Depending on the value of `blkSize`, the array `diagScan` is derived as follows:

```

i = 0
x = 0
y = 0
stopLoop = FALSE
while( !stopLoop ) {
  while( y >= 0 ) {
    if( x < blkSize && y < blkSize ) {
      diagScan[ i ][ 0 ] = x
      diagScan[ i ][ 1 ] = y
      i++
    }
    y--
    x++
  }
  y = x
  x = 0
  if( i >= blkSize * blkSize )
    stopLoop = TRUE
}

```

(6-11)

6.5.4 Horizontal scan order array initialization process

Input to this process is a block size `blkSize`.

Output of this process is the array `horScan[sPos][sComp]`. The array index `sPos` specifies the scan position ranging from 0 to $(\text{blkSize} * \text{blkSize}) - 1$. The array index `sComp` equal to 0 specifies the horizontal component and the array index `sComp` equal to 1 specifies the vertical component. Depending on the value of `blkSize`, the array `horScan` is derived as follows:

```

i = 0
for( y = 0; y < blkSize; y++ )
    for( x = 0; x < blkSize; x++ ) {
        horScan[ i ][ 0 ] = x
        horScan[ i ][ 1 ] = y
        i++
    }

```

(6-12)

6.5.5 Vertical scan order array initialization process

Input to this process is a block size blkSize.

Output of this process is the array verScan[sPos][sComp]. The array index sPos specifies the scan position ranging from 0 to (blkSize * blkSize) – 1. The array index sComp equal to 0 specifies the horizontal component and the array index sComp equal to 1 specifies the vertical component. Depending on the value of blkSize, the array verScan is derived as follows:

```

i = 0
for( x = 0; x < blkSize; x++ )
    for( y = 0; y < blkSize; y++ ) {
        verScan[ i ][ 0 ] = x
        verScan[ i ][ 1 ] = y
        i++
    }

```

(6-13)

6.5.6 Traverse scan order array initialization process

Input to this process is a block size blkSize.

Output of this process is the array travScan[sPos][sComp]. The array index sPos specifies the scan position ranging from 0 to (blkSize * blkSize) – 1, inclusive. The array index sComp equal to 0 specifies the horizontal component and the array index sComp equal to 1 specifies the vertical component. Depending on the value of blkSize, the array travScan is derived as follows:

```

i = 0
for( y = 0; y < blkSize; y++ )
    if( y % 2 == 0 )
        for( x = 0; x < blkSize; x++ ) {
            travScan[ i ][ 0 ] = x
            travScan[ i ][ 1 ] = y
            i++
        }
    else
        for( x = blkSize – 1; x >= 0; x-- ) {
            travScan[ i ][ 0 ] = x
            travScan[ i ][ 1 ] = y
            i++
        }

```

(6-14)

7 Syntax and semantics

7.1 Method of specifying syntax in tabular form

The syntax tables specify a superset of the syntax of all allowed bitstreams. Additional constraints on the syntax may be specified, either directly or indirectly, in other clauses.

NOTE – An actual decoder should implement some means for identifying entry points into the bitstream and some means to identify and handle non-conforming bitstreams. The methods for identifying and handling errors and other such situations are not specified in this Specification.

The following table lists examples of the syntax specification format. When **syntax_element** appears, it specifies that a syntax element is parsed from the bitstream and the bitstream pointer is advanced to the next position beyond the syntax element in the bitstream parsing process.

	Descriptor
/* A statement can be a syntax element with an associated descriptor or can be an expression used to specify conditions for the existence, type and quantity of syntax elements, as in the following two examples */	
syntax_element	ue(v)
conditioning statement	
/* A group of statements enclosed in curly brackets is a compound statement and is treated functionally as a single statement. */	
{	
statement	
statement	
...	
}	
/* A "while" structure specifies a test of whether a condition is true, and if true, specifies evaluation of a statement (or compound statement) repeatedly until the condition is no longer true */	
while(condition)	
statement	
/* A "do ... while" structure specifies evaluation of a statement once, followed by a test of whether a condition is true, and if true, specifies repeated evaluation of the statement until the condition is no longer true */	
do	
statement	
while(condition)	
/* An "if ... else" structure specifies a test of whether a condition is true and, if the condition is true, specifies evaluation of a primary statement, otherwise, specifies evaluation of an alternative statement. The "else" part of the structure and the associated alternative statement is omitted if no alternative statement evaluation is needed */	
if(condition)	
primary statement	
else	
alternative statement	
/* A "for" structure specifies evaluation of an initial statement, followed by a test of a condition, and if the condition is true, specifies repeated evaluation of a primary statement followed by a subsequent statement until the condition is no longer true. */	
for(initial statement; condition; subsequent statement)	
primary statement	

7.2 Specification of syntax functions and descriptors

The functions presented here are used in the syntactical description. These functions are expressed in terms of the value of a bitstream pointer that indicates the position of the next bit to be read by the decoding process from the bitstream.

byte_aligned() is specified as follows:

- If the current position in the bitstream is on a byte boundary, i.e., the next bit in the bitstream is the first bit in a byte, the return value of byte_aligned() is equal to TRUE.
- Otherwise, the return value of byte_aligned() is equal to FALSE.

`more_data_in_byte_stream()`, which is used only in the byte stream NAL unit syntax structure specified in Annex B, is specified as follows:

- If more data follow in the byte stream, the return value of `more_data_in_byte_stream()` is equal to TRUE.
- Otherwise, the return value of `more_data_in_byte_stream()` is equal to FALSE.

`more_data_in_payload()` is specified as follows:

- If `byte_aligned()` is equal to TRUE and the current position in the `sei_payload()` syntax structure is $8 * \text{payloadSize}$ bits from the beginning of the `sei_payload()` syntax structure, the return value of `more_data_in_payload()` is equal to FALSE.
- Otherwise, the return value of `more_data_in_payload()` is equal to TRUE.

`more_rbsp_data()` is specified as follows:

- If there is no more data in the raw byte sequence payload (Rbsp), the return value of `more_rbsp_data()` is equal to FALSE.
- Otherwise, the Rbsp data are searched for the last (least significant, right-most) bit equal to 1 that is present in the Rbsp. Given the position of this bit, which is the first bit (`rbp_stop_one_bit`) of the `rbp_trailing_bits()` syntax structure, the following applies:
 - If there is more data in an Rbsp before the `rbp_trailing_bits()` syntax structure, the return value of `more_rbsp_data()` is equal to TRUE.
 - Otherwise, the return value of `more_rbsp_data()` is equal to FALSE.

The method for enabling determination of whether there is more data in the Rbsp is specified by the application (or in Annex B for applications that use the byte stream format).

`more_rbsp_trailing_data()` is specified as follows:

- If there is more data in an Rbsp, the return value of `more_rbsp_trailing_data()` is equal to TRUE.
- Otherwise, the return value of `more_rbsp_trailing_data()` is equal to FALSE.

`next_bits(n)` provides the next bits in the bitstream for comparison purposes, without advancing the bitstream pointer. It provides a look at the next n bits in the bitstream with n being its argument. When used within the byte stream format as specified in Annex B and fewer than n bits remain within the byte stream, `next_bits(n)` returns a value of 0.

`payload_extension_present()` is specified as follows:

- If the current position in the `sei_payload()` syntax structure is not the position of the last (least significant, right-most) bit that is equal to 1 that is less than $8 * \text{payloadSize}$ bits from the beginning of the syntax structure (i.e., the position of the `payload_bit_equal_to_one` syntax element), the return value of `payload_extension_present()` is equal to TRUE.
- Otherwise, the return value of `payload_extension_present()` is equal to FALSE.

`pic_layer_id(picX)` returns the value of the `nuh_layer_id` of the VCL NAL units in the picture `picX`.

`read_bits(n)` reads the next n bits from the bitstream and advances the bitstream pointer by n bit positions. When n is equal to 0, `read_bits(n)` is specified to return a value equal to 0 and to not advance the bitstream pointer.

The following descriptors specify the parsing process of each syntax element:

- `ae(v)`: context-adaptive arithmetic entropy-coded syntax element. The parsing process for this descriptor is specified in clause 9.3.
- `b(8)`: byte having any pattern of bit string (8 bits). The parsing process for this descriptor is specified by the return value of the function `read_bits(8)`.
- `f(n)`: fixed-pattern bit string using n bits written (from left to right) with the left bit first. The parsing process for this descriptor is specified by the return value of the function `read_bits(n)`.
- `i(n)`: signed integer using n bits. When n is "v" in the syntax table, the number of bits varies in a manner dependent on the value of other syntax elements. The parsing process for this descriptor is specified by the return value of the function `read_bits(n)` interpreted as a two's complement integer representation with most significant bit written first.
- `se(v)`: signed integer 0-th order Exp-Golomb-coded syntax element with the left bit first. The parsing process for this descriptor is specified in clause 9.2.

- **st(v)**: null-terminated string encoded as universal coded character set (UCS) transmission format-8 (UTF-8) characters as specified in ISO/IEC 10646. The parsing process is specified as follows: **st(v)** begins at a byte-aligned position in the bitstream and reads and returns a series of bytes from the bitstream, beginning at the current position and continuing up to but not including the next byte-aligned byte that is equal to 0x00, and advances the bitstream pointer by $(\text{stringLength} + 1) * 8$ bit positions, where **stringLength** is equal to the number of bytes returned.

NOTE – The **st(v)** syntax descriptor is only used in this Specification when the current position in the bitstream is a byte-aligned position.

- **u(n)**: unsigned integer using **n** bits. When **n** is "v" in the syntax table, the number of bits varies in a manner dependent on the value of other syntax elements. The parsing process for this descriptor is specified by the return value of the function **read_bits(n)** interpreted as a binary representation of an unsigned integer with most significant bit written first.
- **ue(v)**: unsigned integer 0-th order Exp-Golomb-coded syntax element with the left bit first. The parsing process for this descriptor is specified in clause 9.2.

7.3 Syntax in tabular form

7.3.1 NAL unit syntax

7.3.1.1 General NAL unit syntax

nal_unit(NumBytesInNalUnit) {	Descriptor

7.4 Semantics

7.4.1 General

Semantics associated with the syntax structures and with the syntax elements within these structures are specified in this clause. When the semantics of a syntax element are specified using a table or a set of tables, any values that are not specified in the table(s) shall not be present in the bitstream unless otherwise specified in this Specification.

7.4.2 NAL unit semantics

7.4.2.1 General NAL unit semantics

NumBytesInNalUnit specifies the size of the NAL unit in bytes. This value is required for decoding of the NAL unit. Some form of demarcation of NAL unit boundaries is necessary to enable inference of NumBytesInNalUnit. One such demarcation method is specified in Annex B for the byte stream format. Other methods of demarcation may be specified outside of this Specification.

NOTE 1 – The video coding layer (VCL) is specified to efficiently represent the content of the video data. The NAL is specified to format that data and provide header information in a manner appropriate for conveyance on a variety of communication channels or storage media. All data are contained in NAL units, each of which contains an integer number of bytes. A NAL unit specifies a generic format for use in both packet-oriented and bitstream systems. The format of NAL units for both packet-oriented transport and byte stream is identical except that each NAL unit can be preceded by a start code prefix and extra padding bytes in the byte stream format specified in Annex B.

rbsp_byte[i] is the *i*-th byte of an RBSP. An RBSP is specified as an ordered sequence of bytes as follows:

The RBSP contains a string of data bits (SODB) as follows:

- If the SODB is empty (i.e., zero bits in length), the RBSP is also empty.
- Otherwise, the RBSP contains the SODB as follows:
 - 1) The first byte of the RBSP contains the first (most significant, left-most) eight bits of the SODB; the next byte of the RBSP contains the next eight bits of the SODB, etc., until fewer than eight bits of the SODB remain.
 - 2) The **rbsp_trailing_bits()** syntax structure is present after the SODB as follows:
 - i) The first (most significant, left-most) bits of the final RBSP byte contain the remaining bits of the SODB (if any).
 - ii) The next bit consists of a single bit equal to 1 (i.e., **rbsp_stop_one_bit**).
 - iii) When the **rbsp_stop_one_bit** is not the last bit of a byte-aligned byte, one or more zero-valued bits (i.e., instances of **rbsp_alignment_zero_bit**) are present to result in byte alignment.
 - 3) One or more **cabac_zero_word** 16-bit syntax elements equal to 0x0000 may be present in some RBSPs after the **rbsp_trailing_bits()** at the end of the RBSP.

Syntax structures having these RBSP properties are denoted in the syntax tables using an "**_rbsp**" suffix. These structures are carried within NAL units as the content of the **rbsp_byte[i]** data bytes. The association of the RBSP syntax structures to the NAL units is as specified in Table 7-1.

NOTE 2 – When the boundaries of the RBSP are known, the decoder can extract the SODB from the RBSP by concatenating the bits of the bytes of the RBSP and discarding the **rbsp_stop_one_bit**, which is the last (least significant, right-most) bit equal to 1, and discarding any following (less significant, farther to the right) bits that follow it, which are equal to 0. The data necessary for the decoding process is contained in the SODB part of the RBSP.

emulation_prevention_three_byte is a byte equal to 0x03. When an **emulation_prevention_three_byte** is present in the NAL unit, it shall be discarded by the decoding process.

The last byte of the NAL unit shall not be equal to 0x00.

Within the NAL unit, the following three-byte sequences shall not occur at any byte-aligned position:

- 0x000000
- 0x000001
- 0x000002

Within the NAL unit, any four-byte sequence that starts with 0x000003 other than the following sequences shall not occur at any byte-aligned position:

- 0x00000300
- 0x00000301
- 0x00000302
- 0x00000303

7.4.2.2 NAL unit header semantics

forbidden_zero_bit shall be equal to 0.

nal_unit_type specifies the type of RBSP data structure contained in the NAL unit as specified in Table 7-1.

NAL units that have **nal_unit_type** in the range of UNSPEC48..UNSPEC63, inclusive, for which semantics are not specified, shall not affect the decoding process specified in this Specification.

NOTE 1 – NAL unit types in the range of UNSPEC48..UNSPEC63 may be used as determined by the application. No decoding process for these values of **nal_unit_type** is specified in this Specification. Since different applications might use these NAL unit types for different purposes, particular care must be exercised in the design of encoders that generate NAL units with these **nal_unit_type** values, and in the design of decoders that interpret the content of NAL units with these **nal_unit_type** values. This Specification does not define any management for these values. These **nal_unit_type** values might only be suitable for use in contexts in which "collisions" of usage (i.e., different definitions of the meaning of the NAL unit content for the same **nal_unit_type** value) are unimportant, or not possible, or are managed – e.g., defined or managed in the controlling application or transport specification, or by controlling the environment in which bitstreams are distributed.

For purposes other than determining the amount of data in the decoding units of the bitstream (as specified in Annex C), decoders shall ignore (remove from the bitstream and discard) the contents of all NAL units that use reserved values of **nal_unit_type**.

NOTE 2 – This requirement allows future definition of compatible extensions to this Specification.

Table 7-1 – NAL unit type codes and NAL unit type classes

nal_unit_type	Name of nal_unit_type	Content of NAL unit and RBSP syntax structure	NAL unit type class
0 1	TRAIL_N TRAIL_R	Coded slice segment of a non-TSA, non-STSA trailing picture slice_segment_layer_rbsp()	VCL
2 3	TSA_N TSA_R	Coded slice segment of a TSA picture slice_segment_layer_rbsp()	VCL
4 5	STSA_N STSA_R	Coded slice segment of an STSA picture slice_segment_layer_rbsp()	VCL
6 7	RADL_N RADL_R	Coded slice segment of a RADL picture slice_segment_layer_rbsp()	VCL
8 9	RASL_N RASL_R	Coded slice segment of a RASL picture slice_segment_layer_rbsp()	VCL

33	SPS_NUT	Sequence parameter set seq_parameter_set_rbsp()	non-VCL
34	PPS_NUT	Picture parameter set pic_parameter_set_rbsp()	non-VCL
35	AUD_NUT	Access unit delimiter access_unit_delimiter_rbsp()	non-VCL
36	EOS_NUT	End of sequence end_of_seq_rbsp()	non-VCL
37	EOB_NUT	End of bitstream end_of_bitstream_rbsp()	non-VCL
38	FD_NUT	Filler data filler_data_rbsp()	non-VCL
39 40	PREFIX_SEI_NUT SUFFIX_SEI_NUT	Supplemental enhancement information sei_rbsp()	non-VCL
41..47	RSV_NVCL41.. RSV_NVCL47	Reserved	non-VCL
48..63	UNSPEC48.. UNSPEC63	Unspecified	non-VCL

NOTE 3 – A clean random access (CRA) picture may have associated random access skipped leading (RASL) or random access decodable leading (RADL) pictures present in the bitstream.

NOTE 4 – A broken link access (BLA) picture having `nal_unit_type` equal to `BLA_W_LP` may have associated RASL or RADL pictures present in the bitstream. A BLA picture having `nal_unit_type` equal to `BLA_W_RADL` does not have associated RASL pictures present in the bitstream, but may have associated RADL pictures in the bitstream. A BLA picture having `nal_unit_type` equal to `BLA_N_LP` does not have associated leading pictures present in the bitstream.

NOTE 5 – An instantaneous decoding refresh (IDR) picture having `nal_unit_type` equal to `IDR_N_LP` does not have associated leading pictures present in the bitstream. An IDR picture having `nal_unit_type` equal to `IDR_W_RADL` does not have associated RASL pictures present in the bitstream, but may have associated RADL pictures in the bitstream.

NOTE 6 – A sub-layer non-reference (SLNR) picture is not included in any of `RefPicSetStCurrBefore`, `RefPicSetStCurrAfter` and `RefPicSetLtCurr` of any picture with the same value of `TemporalId`, and may be discarded without affecting the decodability of other pictures with the same value of `TemporalId`.

All coded slice segment NAL units of an access unit shall have the same value of `nal_unit_type`. A picture or an access unit is also referred to as having a `nal_unit_type` equal to the `nal_unit_type` of the coded slice segment NAL units of the picture or the access unit.

If a picture has `nal_unit_type` equal to `TRAIL_N`, `TSA_N`, `STSA_N`, `RADL_N`, `RASL_N`, `RSV_VCL_N10`, `RSV_VCL_N12` or `RSV_VCL_N14`, the picture is an SLNR picture. Otherwise, the picture is a sub-layer reference picture.

Each picture, other than the first picture in the bitstream in decoding order, is considered to be associated with the previous intra random access point (IRAP) picture in decoding order.

When a picture is a leading picture, it shall be a RADL or RASL picture.

When a picture is a trailing picture, it shall not be a RADL or RASL picture.

When a picture is a leading picture, it shall precede, in decoding order, all trailing pictures that are associated with the same IRAP picture.

No RASL pictures shall be present in the bitstream that are associated with a BLA picture having `nal_unit_type` equal to `BLA_W_RADL` or `BLA_N_LP`.

No RASL pictures shall be present in the bitstream that are associated with an IDR picture.

No RADL pictures shall be present in the bitstream that are associated with a BLA picture having `nal_unit_type` equal to `BLA_N_LP` or that are associated with an IDR picture having `nal_unit_type` equal to `IDR_N_LP`.

NOTE 7 – It is possible to perform random access at the position of an IRAP access unit by discarding all access units before the IRAP access unit (and to correctly decode the IRAP picture and all the subsequent non-RASL pictures in decoding order), provided each parameter set is available (either in the bitstream or by external means not specified in this Specification) when it needs to be activated.

Any picture that has `PicOutputFlag` equal to 1 that precedes an IRAP picture in decoding order shall precede the IRAP picture in output order and shall precede any RADL picture associated with the IRAP picture in output order.

Any RASL picture associated with a CRA or BLA picture shall precede any RADL picture associated with the CRA or BLA picture in output order.

Any RASL picture associated with a CRA picture shall follow, in output order, any IRAP picture that precedes the CRA picture in decoding order.

When `sps_temporal_id_nesting_flag` is equal to 1 and `TemporalId` is greater than 0, the `nal_unit_type` shall be equal to `TSA_R`, `TSA_N`, `RADL_R`, `RADL_N`, `RASL_R` or `RASL_N`.

`nuh_layer_id` specifies the identifier of the layer to which a VCL NAL unit belongs or the identifier of a layer to which a non-VCL NAL unit applies. The value of `nuh_layer_id` shall be in the range of 0 to 62, inclusive. The value of 63 may be specified in the future by ITU-T | ISO/IEC. For purposes other than determining the amount of data in the decoding units of the bitstream, decoders shall ignore all data that follow the value 63 for `nuh_layer_id` in a NAL unit, and decoders conforming to a profile specified in Annex A and not supporting the independent non-base layer decoding (INBLD) capability specified in Annex F shall ignore (i.e., remove from the bitstream and discard) all NAL units with values of `nuh_layer_id` not equal to 0.

NOTE 8 – The value of 63 for `nuh_layer_id` may be used to indicate an extended layer identifier in a future extension of this Specification.

The value of `nuh_layer_id` shall be the same for all VCL NAL units of a coded picture. The value of `nuh_layer_id` of a coded picture is the value of the `nuh_layer_id` of the VCL NAL units of the coded picture.

When `nal_unit_type` is equal to `EOB_NUT`, the value of `nuh_layer_id` shall be equal to 0.

nuh_temporal_id_plus1 minus 1 specifies a temporal identifier for the NAL unit. The value of **nuh_temporal_id_plus1** shall not be equal to 0.

The variable **TemporalId** is specified as follows:

$$\text{TemporalId} = \text{nuh_temporal_id_plus1} - 1 \quad (7-1)$$

When **nal_unit_type** is in the range of **BLA_W_LP** to **RSV_IRAP_VCL23**, inclusive, i.e., the coded slice segment belongs to an IRAP picture, **TemporalId** shall be equal to 0.

When **nal_unit_type** is equal to **TSA_R** or **TSA_N**, **TemporalId** shall not be equal to 0.

When **nuh_layer_id** is equal to 0 and **nal_unit_type** is equal to **STSA_R** or **STSA_N**, **TemporalId** shall not be equal to 0.

The value of **TemporalId** shall be the same for all VCL NAL units of an access unit. The value of **TemporalId** of a coded picture or an access unit is the value of the **TemporalId** of the VCL NAL units of the coded picture or the access unit. The value of **TemporalId** of a sub-layer representation is the greatest value of **TemporalId** of all VCL NAL units in the sub-layer representation.

The value of **TemporalId** for non-VCL NAL units is constrained as follows:

- If **nal_unit_type** is equal to **VPS_NUT** or **SPS_NUT**, **TemporalId** shall be equal to 0 and the **TemporalId** of the access unit containing the NAL unit shall be equal to 0.
- Otherwise if **nal_unit_type** is equal to **EOS_NUT** or **EOB_NUT**, **TemporalId** shall be equal to 0.
- Otherwise, if **nal_unit_type** is equal to **AUD_NUT** or **FD_NUT**, **TemporalId** shall be equal to the **TemporalId** of the access unit containing the NAL unit.
- Otherwise, **TemporalId** shall be greater than or equal to the **TemporalId** of the access unit containing the NAL unit.

NOTE 9 – When the NAL unit is a non-VCL NAL unit, the value of **TemporalId** is equal to the minimum value of the **TemporalId** values of all access units to which the non-VCL NAL unit applies. When **nal_unit_type** is equal to **PPS_NUT**, **TemporalId** may be greater than or equal to the **TemporalId** of the containing access unit, as all picture parameter sets (PPSs) may be included in the beginning of a bitstream, wherein the first coded picture has **TemporalId** equal to 0. When **nal_unit_type** is equal to **PREFIX_SEI_NUT** or **SUFFIX_SEI_NUT**, **TemporalId** may be greater than or equal to the **TemporalId** of the containing access unit, as an SEI NAL unit may contain information, e.g., in a buffering period SEI message or a picture timing SEI message, that applies to a bitstream subset that includes access units for which the **TemporalId** values are greater than the **TemporalId** of the access unit containing the SEI NAL unit.

7.4.2.3 Encapsulation of an SODB within an RBSP (informative)

This clause does not form an integral part of this Specification.

The form of encapsulation of an SODB within an RBSP and the use of the **emulation_prevention_three_byte** for encapsulation of an RBSP within a NAL unit is described for the following purposes:

- To prevent the emulation of start codes within NAL units while allowing any arbitrary SODB to be represented within a NAL unit,
- To enable identification of the end of the SODB within the NAL unit by searching the RBSP for the **rbsp_stop_one_bit** starting at the end of the RBSP,
- To enable a NAL unit to have a size greater than that of the SODB under some circumstances (using one or more **cabac_zero_word** syntax elements).

The encoder can produce a NAL unit from an RBSP by the following procedure:

1. The RBSP data are searched for byte-aligned bits of the following binary patterns:

'00000000 00000000 000000xx' (where 'xx' represents any two-bit pattern: '00', '01', '10', or '11'),

and a byte equal to 0x03 is inserted to replace the bit pattern with the pattern:

'00000000 00000000 00000011 000000xx',

and finally, when the last byte of the RBSP data is equal to 0x00 (which can only occur when the RBSP ends in a **cabac_zero_word**), a final byte equal to 0x03 is appended to the end of the data. The last zero byte of a byte-aligned three-byte sequence 0x000000 in the RBSP (which is replaced by the four-byte sequence 0x00000300) is taken into account when searching the RBSP data for the next occurrence of byte-aligned bits with the binary patterns specified above.

2. The resulting sequence of bytes is then prefixed with the NAL unit header, within which the **nal_unit_type** indicates the type of RBSP data structure in the NAL unit.

The process specified above results in the construction of the entire NAL unit.

This process can allow any SODB to be represented in a NAL unit while ensuring both of the following:

- No byte-aligned start code prefix is emulated within the NAL unit.
- No sequence of 8 zero-valued bits followed by a start code prefix, regardless of byte-alignment, is emulated within the NAL unit.

7.4.2.4 Order of NAL units and association to coded pictures, access units and coded video sequences

7.4.2.4.1 General

This clause specifies constraints on the order of NAL units in the bitstream.

Any order of NAL units in the bitstream obeying these constraints is referred to in the text as the decoding order of NAL units. Within a NAL unit, the syntax in clauses 7.3, D.2 and E.2 specifies the decoding order of syntax elements. Decoders shall be capable of receiving NAL units and their syntax elements in decoding order.

7.4.2.4.2 Order of VPS, SPS and PPS RBSPs and their activation

This clause specifies the activation process of video parameter sets (VPSs), sequence parameter sets (SPSs) and PPSs.

NOTE 1 – The VPS, SPS and PPS mechanism decouples the transmission of infrequently changing information from the transmission of coded block data. VPSs, SPSs and PPSs may, in some applications, be conveyed "out-of-band".

A PPS RBSP includes parameters that can be referred to by the coded slice segment NAL units of one or more coded pictures. Each PPS RBSP is initially considered not active for the base layer at the start of the operation of the decoding process. At most one PPS RBSP is considered active for the base layer at any given moment during the operation of the decoding process, and the activation of any particular PPS RBSP for the base layer results in the deactivation of the previously-active PPS RBSP for the base layer (if any).

When a PPS RBSP (with a particular value of `pps_pic_parameter_set_id`) is not active for the base layer and it is referred to by a coded slice segment NAL unit with `nuh_layer_id` equal to 0 (using a value of `slice_pic_parameter_set_id` equal to the `pps_pic_parameter_set_id` value), it is activated for the base layer. This PPS RBSP is called the active PPS RBSP for the base layer until it is deactivated by the activation of another PPS RBSP for the base layer. A PPS RBSP, with that particular value of `pps_pic_parameter_set_id`, shall be available to the decoding process prior to its activation, included in at least one access unit with `TemporalId` less than or equal to the `TemporalId` of the PPS NAL unit or provided through external means, and the PPS NAL unit containing the PPS RBSP shall have `nuh_layer_id` equal to 0.

Any PPS NAL unit containing the value of `pps_pic_parameter_set_id` for the active PPS RBSP for a coded picture (and consequently for the layer containing the coded picture) shall have the same content as that of the active PPS RBSP for the coded picture, unless it follows the last VCL NAL unit of the coded picture and precedes the first VCL NAL unit of another coded picture.

An SPS RBSP includes parameters that can be referred to by one or more PPS RBSPs or one or more SEI NAL units containing an active parameter sets SEI message. Each SPS RBSP is initially considered not active for the base layer at the start of the operation of the decoding process. At most one SPS RBSP is considered active for the base layer at any given moment during the operation of the decoding process, and the activation of any particular SPS RBSP for the base layer results in the deactivation of the previously-active SPS RBSP for the base layer (if any).

When an SPS RBSP (with a particular value of `sps_seq_parameter_set_id`) is not already active for the base layer and it is referred to by activation of a PPS RBSP (in which `pps_seq_parameter_set_id` is equal to the `sps_seq_parameter_set_id` value) for the base layer or, when `vps_base_layer_internal_flag` is equal to 1 and `vps_base_layer_available_flag` is equal to 1, is referred to by an SEI NAL unit containing an active parameter sets SEI message (in which `active_seq_parameter_set_id[0]` is equal to the `sps_seq_parameter_set_id` value), it is activated for the base layer. This SPS RBSP is called the active SPS RBSP for the base layer until it is deactivated by the activation of another SPS RBSP for the base layer. An SPS RBSP, with that particular value of `sps_seq_parameter_set_id`, shall be available to the decoding process prior to its activation, included in at least one access unit with `TemporalId` equal to 0 or provided through external means, and the SPS NAL unit containing the SPS RBSP shall have `nuh_layer_id` equal to 0. An activated SPS RBSP for the base layer shall remain active for the entire coded video sequence (CVS).

NOTE 2 – Because an IRAP access unit with `NoRasOutputFlag` equal to 1 begins a new CVS and an activated SPS RBSP for the base layer must remain active for the entire CVS, an SPS RBSP can only be activated for the base layer by an active parameter sets SEI message when the active parameter sets SEI message is part of an IRAP access unit with `NoRasOutputFlag` equal to 1.

Any SPS NAL unit with `nuh_layer_id` equal to 0 containing the value of `sps_seq_parameter_set_id` for the active SPS RBSP for the base layer for a CVS shall have the same content as that of the active SPS RBSP for the base layer for the CVS, unless it follows the last access unit of the CVS and precedes the first VCL NAL unit and the first SEI NAL unit containing an active parameter sets SEI message (when present) of another CVS.

A VPS RBSP includes parameters that can be referred to by one or more SPS RBSPs or one or more SEI NAL units containing an active parameter sets SEI message. Each VPS RBSP is initially considered not active at the start of the operation of the decoding process. At most one VPS RBSP is considered active at any given moment during the operation of the decoding process, and the activation of any particular VPS RBSP results in the deactivation of the previously-active VPS RBSP (if any).

When a VPS RBSP (with a particular value of `vps_video_parameter_set_id`) is not already active and it is referred to by activation of an SPS RBSP (in which `sps_video_parameter_set_id` is equal to the `vps_video_parameter_set_id` value) for the base layer, or is referred to by an SEI NAL unit containing an active parameter sets SEI message (in which `active_video_parameter_set_id` is equal to the `vps_video_parameter_set_id` value), it is activated. This VPS RBSP is called the active VPS RBSP until it is deactivated by the activation of another VPS RBSP. A VPS RBSP, with that particular value of `vps_video_parameter_set_id`, shall be available to the decoding process prior to its activation, included in at least one access unit with `TemporalId` equal to 0 or provided through external means, and the VPS NAL unit containing the VPS RBSP shall have `nuh_layer_id` equal to 0. An activated VPS RBSP shall remain active for the entire CVS.

NOTE 3 – Because an IRAP access unit with `NoRasOutputFlag` equal to 1 begins a new CVS and an activated VPS RBSP must remain active for the entire CVS, a VPS RBSP can only be activated by an active parameter sets SEI message when the active parameter sets SEI message is part of an IRAP access unit with `NoRasOutputFlag` equal to 1.

Any VPS NAL unit containing the value of `vps_video_parameter_set_id` for the active VPS RBSP for a CVS shall have the same content as that of the active VPS RBSP for the CVS, unless it follows the last access unit of the CVS and precedes the first VCL NAL unit, the first SPS NAL unit and the first SEI NAL unit containing an active parameter sets SEI message (when present) of another CVS.

NOTE 4 – If VPS RBSP, SPS RBSP or PPS RBSP are conveyed within the bitstream, these constraints impose an order constraint on the NAL units that contain the VPS RBSP, SPS RBSP or PPS RBSP, respectively. Otherwise (VPS RBSP, SPS RBSP or PPS RBSP are conveyed by other means not specified in this Specification), they must be available to the decoding process in a timely fashion such that these constraints are obeyed.

All constraints that are expressed on the relationship between the values of the syntax elements and the values of variables derived from those syntax elements in VPSs, SPSs and PPSs and other syntax elements are expressions of constraints that apply only to the active VPS RBSP, the active SPS RBSP for the base layer and the active PPS RBSP for the base layer. If any VPS RBSP, SPS RBSP and PPS RBSP is present that is never activated in the bitstream, its syntax elements shall have values that would conform to the specified constraints if it was activated by reference in an otherwise conforming bitstream.

NOTE 5 – In the context of this clause, activation of a parameter set RBSP is for the base layer only. Thus, the constraint above on never-activated parameter set RBSPs applies to those parameter set RBSPs with `nuh_layer_id` equal to 0 only, because parameter set RBSPs with `nuh_layer_id` greater than 0 are not allowed to be referred to by the base layer.

During operation of the decoding process (see clause 8), the values of parameters of the active VPS RBSP, the active SPS RBSP for the base layer and the active PPS RBSP for the base layer are considered in effect. For interpretation of SEI messages, the values of the active VPS RBSP, the active SPS RBSP for the base layer and the active PPS RBSP for the base layer for the operation of the decoding process for the VCL NAL units of the coded picture with `nuh_layer_id` equal to 0 in the same access unit are considered in effect unless otherwise specified in the SEI message semantics.

7.4.2.4.3 Order of access units and association to CVSs

A bitstream conforming to this Specification consists of one or more CVSs.

A CVS consists of one or more access units. The order of NAL units and coded pictures and their association to access units is described in clause 7.4.2.4.4.

The first access unit of a CVS is an IRAP access unit with `NoRasOutputFlag` equal to 1.

It is a requirement of bitstream conformance that, when present, the next access unit after an access unit that contains an end of sequence NAL unit shall be an IRAP access unit, which may be an IDR access unit, a BLA access unit, or a CRA access unit.

7.4.2.4.4 Order of NAL units and coded pictures and their association to access units

This clause specifies the order of NAL units and coded pictures and their association to access units for CVSs that conform to one or more of the profiles specified in Annex A and that are decoded using the decoding process specified in clauses 2 through 10.

An access unit consists of one coded picture with `nuh_layer_id` equal to 0, zero or more VCL NAL units with `nuh_layer_id` greater than 0 and zero or more non-VCL NAL units. The association of VCL NAL units to coded pictures is described in clause 7.4.2.4.5.

The first access unit in the bitstream starts with the first NAL unit of the bitstream.

Let firstBIPicNalUnit be the first VCL NAL unit of a coded picture with nuh_layer_id equal to 0. The first of any of the following NAL units preceding firstBIPicNalUnit and succeeding the last VCL NAL unit preceding firstBIPicNalUnit, if any, specifies the start of a new access unit:

NOTE 1 – The last VCL NAL unit preceding firstBIPicNalUnit in decoding order may have nuh_layer_id greater than 0.

- access unit delimiter NAL unit with nuh_layer_id equal to 0 (when present),
- VPS NAL unit with nuh_layer_id equal to 0 (when present),
- SPS NAL unit with nuh_layer_id equal to 0 (when present),
- PPS NAL unit with nuh_layer_id equal to 0 (when present),
- Prefix SEI NAL unit with nuh_layer_id equal to 0 (when present),
- NAL units with nal_unit_type in the range of RSV_NVCL41..RSV_NVCL44 with nuh_layer_id equal to 0 (when present),
- NAL units with nal_unit_type in the range of UNSPEC48..UNSPEC55 with nuh_layer_id equal to 0 (when present).

NOTE 2 – The first NAL unit preceding firstBIPicNalUnit and succeeding the last VCL NAL unit preceding firstBIPicNalUnit, if any, can only be one of the above-listed NAL units.

When there is none of the above NAL units preceding firstBIPicNalUnit and succeeding the last VCL NAL preceding firstBIPicNalUnit, if any, firstBIPicNalUnit starts a new access unit.

The order of the coded pictures and non-VCL NAL units within an access unit shall obey the following constraints:

- When an access unit delimiter NAL unit with nuh_layer_id equal to 0 is present, it shall be the first NAL unit. There shall be at most one access unit delimiter NAL unit with nuh_layer_id equal to 0 in any access unit.
- When any VPS NAL units, SPS NAL units, PPS NAL units, prefix SEI NAL units, NAL units with nal_unit_type in the range of RSV_NVCL41..RSV_NVCL44, or NAL units with nal_unit_type in the range of UNSPEC48..UNSPEC55 are present, they shall not follow the last VCL NAL unit of the access unit.
- NAL units having nal_unit_type equal to FD_NUT or SUFFIX_SEI_NUT or in the range of RSV_NVCL45..RSV_NVCL47 or UNSPEC56..UNSPEC63 shall not precede the first VCL NAL unit of the access unit.
- When an end of sequence NAL unit with nuh_layer_id equal to 0 is present, it shall be the last NAL unit among all NAL units with nuh_layer_id equal to 0 in the access unit other than an end of bitstream NAL unit (when present).
- When an end of bitstream NAL unit is present, it shall be the last NAL unit in the access unit.

NOTE 3 – Decoders conforming to profiles specified in Annex A do not use NAL units with nuh_layer_id greater than 0, e.g., access unit delimiter NAL units with nuh_layer_id greater than 0, for access unit boundary detection, except for identification of a NAL unit as a VCL or non-VCL NAL unit.

The structure of access units not containing any NAL units with nal_unit_type equal to FD_NUT, VPS_NUT, SPS_NUT, PPS_NUT, RSV_VCL_N10, RSV_VCL_R11, RSV_VCL_N12, RSV_VCL_R13, RSV_VCL_N14 or RSV_VCL_R15, RSV_IRAP_VCL22 or RSV_IRAP_VCL23, or in the range of RSV_VCL24..RSV_VCL31, RSV_NVCL41..RSV_NVCL47 or UNSPEC48..UNSPEC63 is shown in Figure 7-1.

Figure 7-1 – Structure of an access unit not containing any NAL units with `nal_unit_type` equal to `FD_NUT`, `SUFFIX_SEI_NUT`, `VPS_NUT`, `SPS_NUT`, `PPS_NUT`, `RSV_VCL_N10`, `RSV_VCL_R11`, `RSV_VCL_N12`, `RSV_VCL_R13`, `RSV_VCL_N14`, `RSV_VCL_R15`, `RSV_IRAP_VCL22` or `RSV_IRAP_VCL23`, or in the range of `RSV_VCL24`..`RSV_VCL31`, `RSV_NVCL41`..`RSV_NVCL47` or `UNSPEC48`..`UNSPEC63`

7.4.2.4.5 Order of VCL NAL units and association to coded pictures

This clause specifies the order of VCL NAL units and association to coded pictures.

Each VCL NAL unit is part of a coded picture.

The order of the VCL NAL units within a coded picture is constrained as follows:

- The first VCL NAL unit of the coded picture shall have `first_slice_segment_in_pic_flag` equal to 1.
- Let `sliceSegAddrA` and `sliceSegAddrB` be the `slice_segment_address` values of any two coded slice segment NAL units A and B within the same coded picture. When either of the following conditions is true, coded slice segment NAL unit A shall precede the coded slice segment NAL unit B:
 - `TileId[CtbAddrRsToTs[sliceSegAddrA]]` is less than `TileId[CtbAddrRsToTs[sliceSegAddrB]]`.
 - `TileId[CtbAddrRsToTs[sliceSegAddrA]]` is equal to `TileId[CtbAddrRsToTs[sliceSegAddrB]]` and `CtbAddrRsToTs[sliceSegAddrA]` is less than `CtbAddrRsToTs[sliceSegAddrB]`.

7.4.3 Raw byte sequence payloads, trailing bits and byte alignment semantics

7.4.3.1 Video parameter set RBSP semantics

NOTE 1 – VPS NAL units are required to be available to the decoding process prior to their activation (either in the bitstream or by external means), as specified in clause 7.4.2.4.2. However, the VPS RBSP contains information that is not necessary for operation of the decoding process specified in clauses 2 through 10 of this Specification. For purposes other than determining the amount of data in the decoding units of the bitstream (as specified in Annex C), decoders conforming to a profile specified in Annex A but not supporting the INBLD capability specified in Annex F may ignore (remove from the bitstream and discard) the content of all VPS NAL units.

Any two instances of the syntax structure `hrd_parameters()` included in a VPS RBSP shall not have the same content.

`vps_video_parameter_set_id` identifies the VPS for reference by other syntax elements.

vps_base_layer_internal_flag and **vps_base_layer_available_flag** specify the following:

- If **vps_base_layer_internal_flag** is equal to 1 and **vps_base_layer_available_flag** is equal to 1, the base layer is present in the bitstream.
- Otherwise, if **vps_base_layer_internal_flag** is equal to 0 and **vps_base_layer_available_flag** is equal to 1, the base layer is provided by an external means not specified in this Specification.
- Otherwise, if **vps_base_layer_internal_flag** is equal to 1 and **vps_base_layer_available_flag** is equal to 0, the base layer is not available (neither present in the bitstream nor provided by external means) but the VPS includes information of the base layer as if it were present in the bitstream.
- Otherwise (**vps_base_layer_internal_flag** is equal to 0 and **vps_base_layer_available_flag** is equal to 0), the base layer is not available (neither present in the bitstream nor provided by external means) but the VPS includes information of the base layer as if it were provided by an external means not specified in this Specification.

vps_max_layers_minus1 plus 1 specifies the maximum allowed number of layers in each CVS referring to the VPS. It is a requirement of bitstream conformance that, when **vps_base_layer_internal_flag** is equal to 0, **vps_max_layers_minus1** shall be greater than 0. **vps_max_layers_minus1** shall be less than 63 in bitstreams conforming to this version of this Specification. The value of 63 for **vps_max_layers_minus1** is reserved for future use by ITU-T | ISO/IEC. Although the value of **vps_max_layers_minus1** is required to be less than 63 in this version of this Specification, decoders shall allow the value of **vps_max_layers_minus1** equal to 63 to appear in the syntax.

NOTE 2 – The value of 63 for **vps_max_layers_minus1** may be used to indicate an extended number of layers in a future extension where more than 63 layers in a bitstream need to be supported.

The variable **MaxLayersMinus1** is set equal to $\text{Min}(62, \text{vps_max_layers_minus1})$.

vps_max_sub_layers_minus1 plus 1 specifies the maximum number of temporal sub-layers that may be present in each CVS referring to the VPS. The value of **vps_max_sub_layers_minus1** shall be in the range of 0 to 6, inclusive.

vps_temporal_id_nesting_flag, when **vps_max_sub_layers_minus1** is greater than 0, specifies whether inter prediction is additionally restricted for CVSs referring to the VPS. When **vps_max_sub_layers_minus1** is equal to 0, **vps_temporal_id_nesting_flag** shall be equal to 1.

NOTE 3 – The syntax element **vps_temporal_id_nesting_flag** is used to indicate that temporal sub-layer up-switching, i.e., switching from decoding of up to any **TemporalId** **tIdN** to decoding up to any **TemporalId** **tIdM** that is greater than **tIdN**, is always possible.

vps_reserved_0xffff_16bits shall be equal to 0xFFFF in bitstreams conforming to this version of this Specification. Other values for **vps_reserved_0xffff_16bits** are reserved for future use by ITU-T | ISO/IEC. Decoders shall ignore the value of **vps_reserved_0xffff_16bits**.

vps_sub_layer_ordering_info_present_flag equal to 1 specifies that **vps_max_dec_pic_buffering_minus1[i]**, **vps_max_num_reorder_pics[i]** and **vps_max_latency_increase_plus1[i]** are present for **vps_max_sub_layers_minus1 + 1** sub-layers. **vps_sub_layer_ordering_info_present_flag** equal to 0 specifies that the values of **vps_max_dec_pic_buffering_minus1[vps_max_sub_layers_minus1]**, **vps_max_num_reorder_pics[vps_max_sub_layers_minus1]** and **vps_max_latency_increase_plus1[vps_max_sub_layers_minus1]** apply to all sub-layers. When **vps_base_layer_internal_flag** is equal to 0, **vps_sub_layer_ordering_info_present_flag** shall be equal to 0 and decoders shall ignore the value of **vps_sub_layer_ordering_info_present_flag**.

vps_max_dec_pic_buffering_minus1[i] plus 1 specifies the maximum required size of the decoded picture buffer for the CVS in units of picture storage buffers when **HighestTid** is equal to **i**. The value of **vps_max_dec_pic_buffering_minus1[i]** shall be in the range of 0 to **MaxDpbSize - 1** (as specified in clause A.4), inclusive. When **i** is greater than 0, **vps_max_dec_pic_buffering_minus1[i]** shall be greater than or equal to **vps_max_dec_pic_buffering_minus1[i - 1]**. When **vps_max_dec_pic_buffering_minus1[i]** is not present for **i** in the range of 0 to **vps_max_sub_layers_minus1 - 1**, inclusive, due to **vps_sub_layer_ordering_info_present_flag** being equal to 0, it is inferred to be equal to **vps_max_dec_pic_buffering_minus1[vps_max_sub_layers_minus1]**. When **vps_base_layer_internal_flag** is equal to 0, **vps_max_dec_pic_buffering_minus1[i]** shall be equal to 0 and decoders shall ignore the value of **vps_max_dec_pic_buffering_minus1[i]**.

vps_max_num_reorder_pics[i] indicates the maximum allowed number of pictures with **PicOutputFlag** equal to 1 that can precede any picture with **PicOutputFlag** equal to 1 in the CVS in decoding order and follow that picture with **PicOutputFlag** equal to 1 in output order when **HighestTid** is equal to **i**. The value of **vps_max_num_reorder_pics[i]** shall be in the range of 0 to **vps_max_dec_pic_buffering_minus1[i]**, inclusive. When **i** is greater than 0, **vps_max_num_reorder_pics[i]** shall be greater than or equal to **vps_max_num_reorder_pics[i - 1]**. When **vps_max_num_reorder_pics[i]** is not present for **i** in the range of 0 to **vps_max_sub_layers_minus1 - 1**, inclusive, due to **vps_sub_layer_ordering_info_present_flag** being equal to 0, it is inferred to be equal to **vps_max_num_reorder_pics[vps_max_sub_layers_minus1]**. When **vps_base_layer_internal_flag** is equal to 0, **vps_max_num_reorder_pics[i]** shall be equal to 0 and decoders shall ignore the value of **vps_max_num_reorder_pics[i]**.

vps_max_latency_increase_plus1[i] not equal to 0 is used to compute the value of **VpsMaxLatencyPictures**[i], which specifies the maximum number of pictures with **PicOutputFlag** equal to 1 that can precede any picture with **PicOutputFlag** equal to 1 in the CVS in output order and follow that picture with **PicOutputFlag** equal to 1 in decoding order when **HighestTid** is equal to i.

When **vps_max_latency_increase_plus1**[i] is not equal to 0, the value of **VpsMaxLatencyPictures**[i] is specified as follows:

$$\text{VpsMaxLatencyPictures}[i] = \text{vps_max_num_reorder_pics}[i] + \text{vps_max_latency_increase_plus1}[i] - 1 \quad (7-2)$$

When **vps_max_latency_increase_plus1**[i] is equal to 0, no corresponding limit is expressed.

The value of **vps_max_latency_increase_plus1**[i] shall be in the range of 0 to $2^{32} - 2$, inclusive. When **vps_max_latency_increase_plus1**[i] is not present for i in the range of 0 to **vps_max_sub_layers_minus1** - 1, inclusive, due to **vps_sub_layer_ordering_info_present_flag** being equal to 0, it is inferred to be equal to **vps_max_latency_increase_plus1**[**vps_max_sub_layers_minus1**].

When **vps_base_layer_internal_flag** is equal to 0, **vps_max_latency_increase_plus1**[i] shall be equal to 0 and decoders shall ignore the value of **vps_max_latency_increase_plus1**[i].

vps_max_layer_id specifies the maximum allowed value of **nuh_layer_id** of all NAL units in each CVS referring to the VPS. **vps_max_layer_id** shall be less than 63 in bitstreams conforming to this version of this Specification. The value of 63 for **vps_max_layer_id** is reserved for future use by ITU-T | ISO/IEC. Although the value of **vps_max_layer_id** is required to be less than 63 in this version of this Specification, decoders shall allow a value of **vps_max_layer_id** equal to 63 to appear in the syntax.

vps_num_layer_sets_minus1 plus 1 specifies the number of layer sets that are specified by the VPS. The value of **vps_num_layer_sets_minus1** shall be in the range of 0 to 1 023, inclusive.

layer_id_included_flag[i][j] equal to 1 specifies that the value of **nuh_layer_id** equal to j is included in the layer identifier list **LayerSetLayerIdList**[i]. **layer_id_included_flag**[i][j] equal to 0 specifies that the value of **nuh_layer_id** equal to j is not included in the layer identifier list **LayerSetLayerIdList**[i].

The value of **NumLayersInIdList**[0] is set equal to 1 and the value of **LayerSetLayerIdList**[0][0] is set equal to 0.

For each value of i in the range of 1 to **vps_num_layer_sets_minus1**, inclusive, the variable **NumLayersInIdList**[i] and the layer identifier list **LayerSetLayerIdList**[i] are derived as follows:

$$\begin{aligned} n &= 0 \\ \text{for}(m = 0; m \leq \text{vps_max_layer_id}; m++) \\ &\quad \text{if}(\text{layer_id_included_flag}[i][m]) \\ &\quad \quad \text{LayerSetLayerIdList}[i][n++] = m \\ \text{NumLayersInIdList}[i] &= n \end{aligned} \quad (7-3)$$

For each value of i in the range of 1 to **vps_num_layer_sets_minus1**, inclusive, **NumLayersInIdList**[i] shall be in the range of 1 to **vps_max_sub_layers_minus1** + 1, inclusive.

When **NumLayersInIdList**[iA] is equal to **NumLayersInIdList**[iB] for any iA and iB in the range of 0 to **vps_num_layer_sets_minus1**, inclusive, with iA not equal to iB, the value of **LayerSetLayerIdList**[iA][n] shall not be equal to **LayerSetLayerIdList**[iB][n] for at least one value of n in the range of 0 to **NumLayersInIdList**[iA], inclusive.

A layer set is identified by the associated layer identifier list. The i-th layer set specified by the VPS is associated with the layer identifier list **LayerSetLayerIdList**[i], for i in the range of 0 to **vps_num_layer_sets_minus1**, inclusive.

A layer set consists of all operation points that are associated with the same layer identifier list.

Each operation point is identified by the associated layer identifier list, denoted as **OpLayerIdList**, which consists of the list of **nuh_layer_id** values of all NAL units included in the operation point, in increasing order of **nuh_layer_id** values, and a variable **OpTid**, which is equal to the highest **TemporalId** of all NAL units included in the operation point. The bitstream subset associated with the operation point identified by **OpLayerIdList** and **OpTid** is the output of the sub-bitstream extraction process as specified in clause 10 with the bitstream, the target highest **TemporalId** equal to **OpTid**, and the target layer identifier list equal to **OpLayerIdList** as inputs. The **OpLayerIdList** and **OpTid** that identify an operation point are also referred to as the **OpLayerIdList** and **OpTid** associated with the operation point, respectively.

vps_timing_info_present_flag equal to 1 specifies that **vps_num_units_in_tick**, **vps_time_scale**, **vps_poc_proportional_to_timing_flag** and **vps_num_hrd_parameters** are present in the VPS.

vps_timing_info_present_flag equal to 0 specifies that **vps_num_units_in_tick**, **vps_time_scale**, **vps_poc_proportional_to_timing_flag** and **vps_num_hrd_parameters** are not present in the VPS.

vps_num_units_in_tick is the number of time units of a clock operating at the frequency **vps_time_scale** Hz that corresponds to one increment (called a clock tick) of a clock tick counter. The value of **vps_num_units_in_tick** shall be greater than 0. A clock tick, in units of seconds, is equal to the quotient of **vps_num_units_in_tick** divided by **vps_time_scale**. For example, when the picture rate of a video signal is 25 Hz, **vps_time_scale** may be equal to 27 000 000 and **vps_num_units_in_tick** may be equal to 1 080 000, and consequently a clock tick may be 0.04 seconds.

vps_time_scale is the number of time units that pass in one second. For example, a time coordinate system that measures time using a 27 MHz clock has a **vps_time_scale** of 27 000 000. The value of **vps_time_scale** shall be greater than 0.

vps_poc_proportional_to_timing_flag equal to 1 indicates that the picture order count value for each picture in the CVS that is not the first picture in the CVS, in decoding order, is proportional to the output time of the picture relative to the output time of the first picture in the CVS. **vps_poc_proportional_to_timing_flag** equal to 0 indicates that the picture order count value for each picture in the CVS that is not the first picture in the CVS, in decoding order, may or may not be proportional to the output time of the picture relative to the output time of the first picture in the CVS.

vps_num_ticks_poc_diff_one_minus1 plus 1 specifies the number of clock ticks corresponding to a difference of picture order count values equal to 1. The value of **vps_num_ticks_poc_diff_one_minus1** shall be in the range of 0 to $2^{32} - 2$, inclusive.

vps_num_hrd_parameters specifies the number of **hrd_parameters()** syntax structures present in the VPS RBSP before the **vps_extension_flag** syntax element. The value of **vps_num_hrd_parameters** shall be in the range of 0 to **vps_num_layer_sets_minus1** + 1, inclusive.

hrd_layer_set_idx[i] specifies the index, into the list of layer sets specified by the VPS, of the layer set to which the *i*-th **hrd_parameters()** syntax structure in the VPS applies. The value of **hrd_layer_set_idx[i]** shall be in the range of (**vps_base_layer_internal_flag** ? 0 : 1) to **vps_num_layer_sets_minus1**, inclusive.

It is a requirement of bitstream conformance that the value of **hrd_layer_set_idx[i]** shall not be equal to the value of **hrd_layer_set_idx[j]** for any value of *j* not equal to *i*.

cprms_present_flag[i] equal to 1 specifies that the HRD parameters that are common for all sub-layers are present in the *i*-th **hrd_parameters()** syntax structure in the VPS. **cprms_present_flag[i]** equal to 0 specifies that the HRD parameters that are common for all sub-layers are not present in the *i*-th **hrd_parameters()** syntax structure in the VPS and are derived to be the same as the (*i* - 1)-th **hrd_parameters()** syntax structure in the VPS. **cprms_present_flag[0]** is inferred to be equal to 1.

vps_extension_flag equal to 0 specifies that no **vps_extension_data_flag** syntax elements are present in the VPS RBSP syntax structure. **vps_extension_flag** equal to 1 specifies that there are **vps_extension_data_flag** syntax elements present in the VPS RBSP syntax structure. Decoders conforming to a profile specified in Annex A but not supporting the INBLD capability specified in Annex F shall ignore all data that follow the value 1 for **vps_extension_flag** in a VPS NAL unit.

vps_extension_data_flag may have any value. Its presence and value do not affect the decoding process of the profiles specified in Annex A. Decoders conforming to a profile specified in Annex A but not supporting the INBLD capability specified in Annex F shall ignore all **vps_extension_data_flag** syntax elements.

7.4.3.2 Sequence parameter set RBSP semantics

7.4.3.2.1 General sequence parameter set RBSP semantics

sps_video_parameter_set_id specifies the value of the **vps_video_parameter_set_id** of the active VPS.

sps_max_sub_layers_minus1 plus 1 specifies the maximum number of temporal sub-layers that may be present in each CVS referring to the SPS. The value of **sps_max_sub_layers_minus1** shall be in the range of 0 to 6, inclusive. The value of **sps_max_sub_layers_minus1** shall be less than or equal to **vps_max_sub_layers_minus1**.

sps_temporal_id_nesting_flag, when **sps_max_sub_layers_minus1** is greater than 0, specifies whether inter prediction is additionally restricted for CVSs referring to the SPS. When **vps_temporal_id_nesting_flag** is equal to 1, **sps_temporal_id_nesting_flag** shall be equal to 1. When **sps_max_sub_layers_minus1** is equal to 0, **sps_temporal_id_nesting_flag** shall be equal to 1.

NOTE 1 – The syntax element **sps_temporal_id_nesting_flag** is used to indicate that temporal up-switching, i.e., switching from decoding up to any TemporalId tldN to decoding up to any TemporalId tldM that is greater than tldN, is always possible in the CVS.

sps_seq_parameter_set_id provides an identifier for the SPS for reference by other syntax elements. The value of **sps_seq_parameter_set_id** shall be in the range of 0 to 15, inclusive.

chroma_format_idc specifies the chroma sampling relative to the luma sampling as specified in clause 6.2. The value of **chroma_format_idc** shall be in the range of 0 to 3, inclusive.

separate_colour_plane_flag equal to 1 specifies that the three colour components of the 4:4:4 chroma format are coded separately. **separate_colour_plane_flag** equal to 0 specifies that the colour components are not coded separately. When **separate_colour_plane_flag** is not present, it is inferred to be equal to 0. When **separate_colour_plane_flag** is equal to 1, the coded picture consists of three separate components, each of which consists of coded samples of one colour plane (Y, Cb, or Cr) and uses the monochrome coding syntax. In this case, each colour plane is associated with a specific **colour_plane_id** value.

NOTE 2 – There is no dependency in decoding processes between the colour planes having different **colour_plane_id** values. For example, the decoding process of a monochrome picture with one value of **colour_plane_id** does not use any data from monochrome pictures having different values of **colour_plane_id** for inter prediction.

Depending on the value of **separate_colour_plane_flag**, the value of the variable **ChromaArrayType** is assigned as follows:

- If **separate_colour_plane_flag** is equal to 0, **ChromaArrayType** is set equal to **chroma_format_idc**.
- Otherwise (**separate_colour_plane_flag** is equal to 1), **ChromaArrayType** is set equal to 0.

pic_width_in_luma_samples specifies the width of each decoded picture in units of luma samples. **pic_width_in_luma_samples** shall not be equal to 0 and shall be an integer multiple of **MinCbSizeY**.

pic_height_in_luma_samples specifies the height of each decoded picture in units of luma samples. **pic_height_in_luma_samples** shall not be equal to 0 and shall be an integer multiple of **MinCbSizeY**.

conformance_window_flag equal to 1 indicates that the conformance cropping window offset parameters follow next in the SPS. **conformance_window_flag** equal to 0 indicates that the conformance cropping window offset parameters are not present.

conf_win_left_offset, **conf_win_right_offset**, **conf_win_top_offset** and **conf_win_bottom_offset** specify the samples of the pictures in the CVS that are output from the decoding process, in terms of a rectangular region specified in picture coordinates for output. When **conformance_window_flag** is equal to 0, the values of **conf_win_left_offset**, **conf_win_right_offset**, **conf_win_top_offset** and **conf_win_bottom_offset** are inferred to be equal to 0.

The conformance cropping window contains the luma samples with horizontal picture coordinates from $\text{SubWidthC} * \text{conf_win_left_offset}$ to $\text{pic_width_in_luma_samples} - (\text{SubWidthC} * \text{conf_win_right_offset} + 1)$ and vertical picture coordinates from $\text{SubHeightC} * \text{conf_win_top_offset}$ to $\text{pic_height_in_luma_samples} - (\text{SubHeightC} * \text{conf_win_bottom_offset} + 1)$, inclusive.

The value of $\text{SubWidthC} * (\text{conf_win_left_offset} + \text{conf_win_right_offset})$ shall be less than **pic_width_in_luma_samples**, and the value of $\text{SubHeightC} * (\text{conf_win_top_offset} + \text{conf_win_bottom_offset})$ shall be less than **pic_height_in_luma_samples**.

When **ChromaArrayType** is not equal to 0, the corresponding specified samples of the two chroma arrays are the samples having picture coordinates ($x / \text{SubWidthC}$, $y / \text{SubHeightC}$), where (x , y) are the picture coordinates of the specified luma samples.

NOTE 3 – The conformance cropping window offset parameters are only applied at the output. All internal decoding processes are applied to the uncropped picture size.

bit_depth_luma_minus8 specifies the bit depth of the samples of the luma array **BitDepth_Y** and the value of the luma quantization parameter range offset **QpBdOffset_Y** as follows:

$$\text{BitDepth}_Y = 8 + \text{bit_depth_luma_minus8} \quad (7-4)$$

$$\text{QpBdOffset}_Y = 6 * \text{bit_depth_luma_minus8} \quad (7-5)$$

bit_depth_luma_minus8 shall be in the range of 0 to 8, inclusive.

bit_depth_chroma_minus8 specifies the bit depth of the samples of the chroma arrays **BitDepth_C** and the value of the chroma quantization parameter range offset **QpBdOffset_C** as follows:

$$\text{BitDepth}_C = 8 + \text{bit_depth_chroma_minus8} \quad (7-6)$$

$$\text{QpBdOffset}_C = 6 * \text{bit_depth_chroma_minus8} \quad (7-7)$$

bit_depth_chroma_minus8 shall be in the range of 0 to 8, inclusive.

log2_max_pic_order_cnt_lsb_minus4 specifies the value of the variable **MaxPicOrderCntLsb** that is used in the decoding process for picture order count as follows:

$$\text{MaxPicOrderCntLsb} = 2^{(\log_2 \text{max_pic_order_cnt_lsb_minus4} + 4)} \quad (7-8)$$

The value of `log2_max_pic_order_cnt_lsb_minus4` shall be in the range of 0 to 12, inclusive.

`sps_sub_layer_ordering_info_present_flag` equal to 1 specifies that `sps_max_dec_pic_buffering_minus1[i]`, `sps_max_num_reorder_pics[i]` and `sps_max_latency_increase_plus1[i]` are present for `sps_max_sub_layers_minus1 + 1` sub-layers. `sps_sub_layer_ordering_info_present_flag` equal to 0 specifies that the values of `sps_max_dec_pic_buffering_minus1[sps_max_sub_layers_minus1]`, `sps_max_num_reorder_pics[sps_max_sub_layers_minus1]` and `sps_max_latency_increase_plus1[sps_max_sub_layers_minus1]` apply to all sub-layers.

`sps_max_dec_pic_buffering_minus1[i]` plus 1 specifies the maximum required size of the decoded picture buffer for the CVS in units of picture storage buffers when `HighestTid` is equal to `i`. The value of `sps_max_dec_pic_buffering_minus1[i]` shall be in the range of 0 to `MaxDpbSize - 1`, inclusive, where `MaxDpbSize` is as specified in clause A.4. When `i` is greater than 0, `sps_max_dec_pic_buffering_minus1[i]` shall be greater than or equal to `sps_max_dec_pic_buffering_minus1[i - 1]`. The value of `sps_max_dec_pic_buffering_minus1[i]` shall be less than or equal to `vps_max_dec_pic_buffering_minus1[i]` for each value of `i`. When `sps_max_dec_pic_buffering_minus1[i]` is not present for `i` in the range of 0 to `sps_max_sub_layers_minus1 - 1`, inclusive, due to `sps_sub_layer_ordering_info_present_flag` being equal to 0, it is inferred to be equal to `sps_max_dec_pic_buffering_minus1[sps_max_sub_layers_minus1]`.

`sps_max_num_reorder_pics[i]` indicates the maximum allowed number of pictures with `PicOutputFlag` equal to 1 that can precede any picture with `PicOutputFlag` equal to 1 in the CVS in decoding order and follow that picture with `PicOutputFlag` equal to 1 in output order when `HighestTid` is equal to `i`. The value of `sps_max_num_reorder_pics[i]` shall be in the range of 0 to `sps_max_dec_pic_buffering_minus1[i]`, inclusive. When `i` is greater than 0, `sps_max_num_reorder_pics[i]` shall be greater than or equal to `sps_max_num_reorder_pics[i - 1]`. The value of `sps_max_num_reorder_pics[i]` shall be less than or equal to `vps_max_num_reorder_pics[i]` for each value of `i`. When `sps_max_num_reorder_pics[i]` is not present for `i` in the range of 0 to `sps_max_sub_layers_minus1 - 1`, inclusive, due to `sps_sub_layer_ordering_info_present_flag` being equal to 0, it is inferred to be equal to `sps_max_num_reorder_pics[sps_max_sub_layers_minus1]`.

`sps_max_latency_increase_plus1[i]` not equal to 0 is used to compute the value of `SpsMaxLatencyPictures[i]`, which specifies the maximum number of pictures with `PicOutputFlag` equal to 1 that can precede any picture with `PicOutputFlag` equal to 1 in the CVS in output order and follow that picture with `PicOutputFlag` equal to 1 in decoding order when `HighestTid` is equal to `i`.

When `sps_max_latency_increase_plus1[i]` is not equal to 0, the value of `SpsMaxLatencyPictures[i]` is specified as follows:

$$\text{SpsMaxLatencyPictures}[i] = \text{sps_max_num_reorder_pics}[i] + \text{sps_max_latency_increase_plus1}[i] - 1 \quad (7-9)$$

When `sps_max_latency_increase_plus1[i]` is equal to 0, no corresponding limit is expressed.

The value of `sps_max_latency_increase_plus1[i]` shall be in the range of 0 to $2^{32} - 2$, inclusive. When `vps_max_latency_increase_plus1[i]` is not equal to 0, the value of `sps_max_latency_increase_plus1[i]` shall not be equal to 0 and shall be less than or equal to `vps_max_latency_increase_plus1[i]` for each value of `i`. When `sps_max_latency_increase_plus1[i]` is not present for `i` in the range of 0 to `sps_max_sub_layers_minus1 - 1`, inclusive, due to `sps_sub_layer_ordering_info_present_flag` being equal to 0, it is inferred to be equal to `sps_max_latency_increase_plus1[sps_max_sub_layers_minus1]`.

`log2_min_luma_coding_block_size_minus3` plus 3 specifies the minimum luma coding block size.

`log2_diff_max_min_luma_coding_block_size` specifies the difference between the maximum and minimum luma coding block size.

The variables `MinCbLog2SizeY`, `CtbLog2SizeY`, `MinCbSizeY`, `CtbSizeY`, `PicWidthInMinCbsY`, `PicWidthInCtbsY`, `PicHeightInMinCbsY`, `PicHeightInCtbsY`, `PicSizeInMinCbsY`, `PicSizeInCtbsY`, `PicSizeInSamplesY`, `PicWidthInSamplesC` and `PicHeightInSamplesC` are derived as follows:

$$\text{MinCbLog2SizeY} = \text{log2_min_luma_coding_block_size_minus3} + 3 \quad (7-10)$$

$$\text{CtbLog2SizeY} = \text{MinCbLog2SizeY} + \text{log2_diff_max_min_luma_coding_block_size} \quad (7-11)$$

$$\text{MinCbSizeY} = 1 \ll \text{MinCbLog2SizeY} \quad (7-12)$$

$$\text{CtbSizeY} = 1 \ll \text{CtbLog2SizeY} \quad (7-13)$$

$$\text{PicWidthInMinCbsY} = \text{pic_width_in_luma_samples} / \text{MinCbSizeY} \quad (7-14)$$

$$\text{PicWidthInCtbsY} = \text{Ceil}(\text{pic_width_in_luma_samples} \div \text{CtbSizeY}) \quad (7-15)$$

$$\text{PicHeightInMinCbsY} = \text{pic_height_in_luma_samples} / \text{MinCbSizeY} \quad (7-16)$$

$$\text{PicHeightInCtbsY} = \text{Ceil}(\text{pic_height_in_luma_samples} \div \text{CtbSizeY}) \quad (7-17)$$

$$\text{PicSizeInMinCbsY} = \text{PicWidthInMinCbsY} * \text{PicHeightInMinCbsY} \quad (7-18)$$

$$\text{PicSizeInCtbsY} = \text{PicWidthInCtbsY} * \text{PicHeightInCtbsY} \quad (7-19)$$

$$\text{PicSizeInSamplesY} = \text{pic_width_in_luma_samples} * \text{pic_height_in_luma_samples} \quad (7-20)$$

$$\text{PicWidthInSamplesC} = \text{pic_width_in_luma_samples} / \text{SubWidthC} \quad (7-21)$$

$$\text{PicHeightInSamplesC} = \text{pic_height_in_luma_samples} / \text{SubHeightC} \quad (7-22)$$

The variables CtbWidthC and CtbHeightC, which specify the width and height, respectively, of the array for each chroma CTB, are derived as follows:

- If chroma_format_idc is equal to 0 (monochrome) or separate_colour_plane_flag is equal to 1, CtbWidthC and CtbHeightC are both equal to 0.
- Otherwise, CtbWidthC and CtbHeightC are derived as follows:

$$\text{CtbWidthC} = \text{CtbSizeY} / \text{SubWidthC} \quad (7-23)$$

$$\text{CtbHeightC} = \text{CtbSizeY} / \text{SubHeightC} \quad (7-24)$$

log2_min_luma_transform_block_size_minus2 plus 2 specifies the minimum luma transform block size.

The variable MinTbLog2SizeY is set equal to log2_min_luma_transform_block_size_minus2 + 2. The CVS shall not contain data that result in MinTbLog2SizeY greater than or equal to MinCbLog2SizeY.

log2_diff_max_min_luma_transform_block_size specifies the difference between the maximum and minimum luma transform block size.

The variable MaxTbLog2SizeY is set equal to log2_min_luma_transform_block_size_minus2 + 2 + log2_diff_max_min_luma_transform_block_size.

The CVS shall not contain data that result in MaxTbLog2SizeY greater than Min(CtbLog2SizeY, 5).

The array ScanOrder[log2BlockSize][scanIdx][sPos][sComp] specifies the mapping of the scan position sPos, ranging from 0 to (1 << log2BlockSize) * (1 << log2BlockSize) – 1, inclusive, to horizontal and vertical components of the scan-order matrix. The array index scanIdx equal to 0 specifies an up-right diagonal scan order, scanIdx equal to 1 specifies a horizontal scan order, scanIdx equal to 2 specifies a vertical scan order, and scanIdx equal to 3 specifies a traverse scan order. The array index sComp equal to 0 specifies the horizontal component and the array index sComp equal to 1 specifies the vertical component. The array ScanOrder is derived as follows:

For the variable log2BlockSize ranging from 0 to 5, inclusive, the scanning order array ScanOrder is derived as follows:

- For log2BlockSize ranging from 0 to 3, inclusive, the up-right diagonal scan order array initialization process as specified in clause 6.5.3 is invoked with 1 << log2BlockSize as input, and the output is assigned to ScanOrder[log2BlockSize][0].
- For log2BlockSize ranging from 0 to 3, inclusive, the horizontal scan order array initialization process as specified in clause 6.5.4 is invoked with 1 << log2BlockSize as input, and the output is assigned to ScanOrder[log2BlockSize][1].
- For log2BlockSize ranging from 0 to 3, inclusive, the vertical scan order array initialization process as specified in clause 6.5.5 is invoked with 1 << log2BlockSize as input, and the output is assigned to ScanOrder[log2BlockSize][2].
- For log2BlockSize ranging from 2 to 5, inclusive, the traverse scan order array initialization process as specified in clause 6.5.6 is invoked with 1 << log2BlockSize as input, and the output is assigned to ScanOrder[log2BlockSize][3].

max_transform_hierarchy_depth_inter specifies the maximum hierarchy depth for transform units of coding units coded in inter prediction mode. The value of **max_transform_hierarchy_depth_inter** shall be in the range of 0 to $\text{CtbLog2SizeY} - \text{MinTbLog2SizeY}$, inclusive.

max_transform_hierarchy_depth_intra specifies the maximum hierarchy depth for transform units of coding units coded in intra prediction mode. The value of **max_transform_hierarchy_depth_intra** shall be in the range of 0 to $\text{CtbLog2SizeY} - \text{MinTbLog2SizeY}$, inclusive.

scaling_list_enabled_flag equal to 1 specifies that a scaling list is used for the scaling process for transform coefficients. **scaling_list_enabled_flag** equal to 0 specifies that scaling list is not used for the scaling process for transform coefficients.

sps_scaling_list_data_present_flag equal to 1 specifies that the **scaling_list_data()** syntax structure is present in the SPS. **sps_scaling_list_data_present_flag** equal to 0 specifies that the **scaling_list_data()** syntax structure is not present in the SPS. When not present, the value of **sps_scaling_list_data_present_flag** is inferred to be equal to 0.

amp_enabled_flag equal to 1 specifies that asymmetric motion partitions, i.e., **PartMode** equal to **PART_2NxN**, **PART_2NxN_D**, **PART_nLx2N** or **PART_nRx2N**, may be used in CTBs. **amp_enabled_flag** equal to 0 specifies that asymmetric motion partitions cannot be used in CTBs.

sample_adaptive_offset_enabled_flag equal to 1 specifies that the sample adaptive offset process is applied to the reconstructed picture after the deblocking filter process. **sample_adaptive_offset_enabled_flag** equal to 0 specifies that the sample adaptive offset process is not applied to the reconstructed picture after the deblocking filter process.

pcm_enabled_flag equal to 0 specifies that PCM-related syntax (**pcm_sample_bit_depth_luma_minus1**, **pcm_sample_bit_depth_chroma_minus1**, **log2_min_pcm_luma_coding_block_size_minus3**, **log2_diff_max_min_pcm_luma_coding_block_size**, **pcm_loop_filter_disabled_flag**, **pcm_flag**, **pcm_alignment_zero_bit** syntax elements and **pcm_sample()** syntax structure) is not present in the CVS.

NOTE 4 – When **MinCbLog2SizeY** is equal to 6 and **pcm_enabled_flag** is equal to 1, PCM sample data-related syntax (**pcm_flag**, **pcm_alignment_zero_bit** syntax elements and **pcm_sample()** syntax structure) is not present in the CVS, because the maximum size of coding blocks that can convey PCM sample data-related syntax is restricted to be less than or equal to $\text{Min}(\text{CtbLog2SizeY}, 5)$. Hence, **MinCbLog2SizeY** equal to 6 with **pcm_enabled_flag** equal to 1 is not an appropriate setting to convey PCM sample data in the CVS.

pcm_sample_bit_depth_luma_minus1 specifies the number of bits used to represent each of PCM sample values of the luma component as follows:

$$\text{PcmBitDepth}_Y = \text{pcm_sample_bit_depth_luma_minus1} + 1 \quad (7-25)$$

The value of PcmBitDepth_Y shall be less than or equal to the value of BitDepth_Y .

pcm_sample_bit_depth_chroma_minus1 specifies the number of bits used to represent each of PCM sample values of the chroma components as follows:

$$\text{PcmBitDepth}_C = \text{pcm_sample_bit_depth_chroma_minus1} + 1 \quad (7-26)$$

The value of PcmBitDepth_C shall be less than or equal to the value of BitDepth_C . When **ChromaArrayType** is equal to 0, **pcm_sample_bit_depth_chroma_minus1** is not used in the decoding process and decoders shall ignore its value.

log2_min_pcm_luma_coding_block_size_minus3 plus 3 specifies the minimum size of coding blocks with **pcm_flag** equal to 1.

The variable $\text{Log2MinIpcmCbSizeY}$ is set equal to **log2_min_pcm_luma_coding_block_size_minus3** + 3. The value of $\text{Log2MinIpcmCbSizeY}$ shall be in the range of $\text{Min}(\text{MinCbLog2SizeY}, 5)$ to $\text{Min}(\text{CtbLog2SizeY}, 5)$, inclusive.

log2_diff_max_min_pcm_luma_coding_block_size specifies the difference between the maximum and minimum size of coding blocks with **pcm_flag** equal to 1.

The variable $\text{Log2MaxIpcmCbSizeY}$ is set equal to **log2_diff_max_min_pcm_luma_coding_block_size** + $\text{Log2MinIpcmCbSizeY}$. The value of $\text{Log2MaxIpcmCbSizeY}$ shall be less than or equal to $\text{Min}(\text{CtbLog2SizeY}, 5)$.

pcm_loop_filter_disabled_flag specifies whether the loop filter process is disabled on reconstructed samples in a coding unit with **pcm_flag** equal to 1 as follows:

- If **pcm_loop_filter_disabled_flag** is equal to 1, the deblocking filter and sample adaptive offset filter processes on the reconstructed samples in a coding unit with **pcm_flag** equal to 1 are disabled.
- Otherwise (**pcm_loop_filter_disabled_flag** value is equal to 0), the deblocking filter and sample adaptive offset filter processes on the reconstructed samples in a coding unit with **pcm_flag** equal to 1 are not disabled.

When **pcm_loop_filter_disabled_flag** is not present, it is inferred to be equal to 0.

num_short_term_ref_pic_sets specifies the number of `st_ref_pic_set()` syntax structures included in the SPS. The value of `num_short_term_ref_pic_sets` shall be in the range of 0 to 64, inclusive.

NOTE 5 – A decoder should allocate memory for a total number of `num_short_term_ref_pic_sets + 1` `st_ref_pic_set()` syntax structures since there may be a `st_ref_pic_set()` syntax structure directly signalled in the slice headers of a current picture. A `st_ref_pic_set()` syntax structure directly signalled in the slice headers of a current picture has an index equal to `num_short_term_ref_pic_sets`.

long_term_ref_pics_present_flag equal to 0 specifies that no long-term reference picture is used for inter prediction of any coded picture in the CVS. **long_term_ref_pics_present_flag** equal to 1 specifies that long-term reference pictures may be used for inter prediction of one or more coded pictures in the CVS.

num_long_term_ref_pics_sps specifies the number of candidate long-term reference pictures that are specified in the SPS. The value of `num_long_term_ref_pics_sps` shall be in the range of 0 to 32, inclusive.

lt_ref_pic_poc_lsb_sps[i] specifies the picture order count modulo `MaxPicOrderCntLsb` of the *i*-th candidate long-term reference picture specified in the SPS. The number of bits used to represent `lt_ref_pic_poc_lsb_sps[i]` is equal to `log2_max_pic_order_cnt_lsb_minus4 + 4`.

used_by_curr_pic_lt_sps_flag[i] equal to 0 specifies that the *i*-th candidate long-term reference picture specified in the SPS is not used for reference by a picture that includes in its long-term reference picture set (RPS) the *i*-th candidate long-term reference picture specified in the SPS.

sps_temporal_mvp_enabled_flag equal to 1 specifies that `slice_temporal_mvp_enabled_flag` is present in the slice headers of non-IDR pictures in the CVS. **sps_temporal_mvp_enabled_flag** equal to 0 specifies that `slice_temporal_mvp_enabled_flag` is not present in slice headers and that temporal motion vector predictors are not used in the CVS.

strong_intra_smoothing_enabled_flag equal to 1 specifies that bi-linear interpolation is conditionally used in the intra prediction filtering process in the CVS as specified in clause 8.4.4.2.3. **strong_intra_smoothing_enabled_flag** equal to 0 specifies that the bi-linear interpolation is not used in the CVS.

vui_parameters_present_flag equal to 1 specifies that the `vui_parameters()` syntax structure as specified in Annex E is present. **vui_parameters_present_flag** equal to 0 specifies that the `vui_parameters()` syntax structure as specified in Annex E is not present.

sps_extension_present_flag equal to 1 specifies that the syntax elements `sps_range_extension_flag`, `sps_multilayer_extension_flag`, `sps_3d_extension_flag`, `sps_scc_extension_flag`, and `sps_extension_4bits` are present in the SPS RBSP syntax structure. **sps_extension_present_flag** equal to 0 specifies that these syntax elements are not present.

sps_range_extension_flag equal to 1 specifies that the `sps_range_extension()` syntax structure is present in the SPS RBSP syntax structure. **sps_range_extension_flag** equal to 0 specifies that this syntax structure is not present. When not present, the value of `sps_range_extension_flag` is inferred to be equal to 0.

sps_multilayer_extension_flag equal to 1 specifies that the `sps_multilayer_extension()` syntax structure (specified in Annex F) is present in the SPS RBSP syntax structure. **sps_multilayer_extension_flag** equal to 0 specifies that the `sps_multilayer_extension()` syntax structure is not present. When not present, the value of `sps_multilayer_extension_flag` is inferred to be equal to 0.

sps_3d_extension_flag equal to 1 specifies that the `sps_3d_extension()` syntax structure (specified in Annex I) is present in the SPS RBSP syntax structure. **sps_3d_extension_flag** equal to 0 specifies that the `sps_3d_extension()` syntax structure is not present. When not present, the value of `sps_3d_extension_flag` is inferred to be equal to 0.

sps_scc_extension_flag equal to 1 specifies that the `sps_scc_extension()` syntax structure is present in the SPS RBSP syntax structure. **sps_scc_extension_flag** equal to 0 specifies that this syntax structure is not present. When not present, the value of `sps_scc_extension_flag` is inferred to be equal to 0.

sps_extension_4bits equal to 0 specifies that no `sps_extension_data_flag` syntax elements are present in the SPS RBSP syntax structure. When present, `sps_extension_4bits` shall be equal to 0 in bitstreams conforming to this version of this Specification. Values of `sps_extension_4bits` not equal to 0 are reserved for future use by ITU-T | ISO/IEC. Decoders shall allow the value of `sps_extension_4bits` to be not equal to 0 and shall ignore all `sps_extension_data_flag` syntax elements in an SPS NAL unit. When not present, the value of `sps_extension_4bits` is inferred to be equal to 0.

sps_extension_data_flag may have any value. Its presence and value do not affect the decoding process specified in this version of this Specification. Decoders conforming to this version of this Specification shall ignore all `sps_extension_data_flag` syntax elements.

7.4.3.2.2 Sequence parameter set range extension semantics

transform_skip_rotation_enabled_flag equal to 1 specifies that a rotation is applied to the residual data block for intra 4x4 blocks coded using a transform skip operation. **transform_skip_rotation_enabled_flag** equal to 0 specifies that this rotation is not applied. When not present, the value of **transform_skip_rotation_enabled_flag** is inferred to be equal to 0.

transform_skip_context_enabled_flag equal to 1 specifies that a particular context is used for the parsing of the **sig_coeff_flag** for transform blocks with a skipped transform. **transform_skip_context_enabled_flag** equal to 0 specifies that the presence or absence of transform skipping or a transform bypass for transform blocks is not used in the context selection for this flag. When not present, the value of **transform_skip_context_enabled_flag** is inferred to be equal to 0.

implicit_rdp_pcm_enabled_flag equal to 1 specifies that the residual modification process for blocks using a transform bypass may be used for intra blocks in the CVS. **implicit_rdp_pcm_enabled_flag** equal to 0 specifies that the residual modification process is not used for intra blocks in the CVS. When not present, the value of **implicit_rdp_pcm_enabled_flag** is inferred to be equal to 0.

explicit_rdp_pcm_enabled_flag equal to 1 specifies that the residual modification process for blocks using a transform bypass may be used for inter blocks in the CVS. **explicit_rdp_pcm_enabled_flag** equal to 0 specifies that the residual modification process is not used for inter blocks in the CVS. When not present, the value of **explicit_rdp_pcm_enabled_flag** is inferred to be equal to 0.

extended_precision_processing_flag equal to 1 specifies that an extended dynamic range is used for transform coefficients and transform processing. **extended_precision_processing_flag** equal to 0 specifies that the extended dynamic range is not used. When not present, the value of **extended_precision_processing_flag** is inferred to be equal to 0.

The variables CoeffMin_Y , CoeffMin_C , CoeffMax_Y and CoeffMax_C are derived as follows:

$$\text{CoeffMin}_Y = -(1 \ll (\text{extended_precision_processing_flag} ? \text{Max}(15, \text{BitDepth}_Y + 6) : 15)) \quad (7-27)$$

$$\text{CoeffMin}_C = -(1 \ll (\text{extended_precision_processing_flag} ? \text{Max}(15, \text{BitDepth}_C + 6) : 15)) \quad (7-28)$$

$$\text{CoeffMax}_Y = (1 \ll (\text{extended_precision_processing_flag} ? \text{Max}(15, \text{BitDepth}_Y + 6) : 15)) - 1 \quad (7-29)$$

$$\text{CoeffMax}_C = (1 \ll (\text{extended_precision_processing_flag} ? \text{Max}(15, \text{BitDepth}_C + 6) : 15)) - 1 \quad (7-30)$$

intra_smoothing_disabled_flag equal to 1 specifies that the filtering process of neighbouring samples is unconditionally disabled for intra prediction. **intra_smoothing_disabled_flag** equal to 0 specifies that the filtering process of neighbouring samples is not disabled. When not present, the value of **intra_smoothing_disabled_flag** is inferred to be equal to 0.

high_precision_offsets_enabled_flag equal to 1 specifies that weighted prediction offset values are signalled using a bit-depth-dependent precision. **high_precision_offsets_enabled_flag** equal to 0 specifies that weighted prediction offset values are signalled with a precision equivalent to eight bit processing.

The variables WpOffsetBdShift_Y , WpOffsetBdShift_C , $\text{WpOffsetHalfRange}_Y$ and $\text{WpOffsetHalfRange}_C$ are derived as follows:

$$\text{WpOffsetBdShift}_Y = \text{high_precision_offsets_enabled_flag} ? 0 : (\text{BitDepth}_Y - 8) \quad (7-31)$$

$$\text{WpOffsetBdShift}_C = \text{high_precision_offsets_enabled_flag} ? 0 : (\text{BitDepth}_C - 8) \quad (7-32)$$

$$\text{WpOffsetHalfRange}_Y = 1 \ll (\text{high_precision_offsets_enabled_flag} ? (\text{BitDepth}_Y - 1) : 7) \quad (7-33)$$

$$\text{WpOffsetHalfRange}_C = 1 \ll (\text{high_precision_offsets_enabled_flag} ? (\text{BitDepth}_C - 1) : 7) \quad (7-34)$$

persistent_rice_adaptation_enabled_flag equal to 1 specifies that the Rice parameter derivation for the binarization of **coeff_abs_level_remaining[]** is initialized at the start of each sub-block using mode dependent statistics accumulated from previous sub-blocks. **persistent_rice_adaptation_enabled_flag** equal to 0 specifies that no previous sub-block state is used in Rice parameter derivation. When not present, the value of **persistent_rice_adaptation_enabled_flag** is inferred to be equal to 0.

cabac_bypass_alignment_enabled_flag equal to 1 specifies that a context-based adaptive binary arithmetic coding (CABAC) alignment process is used prior to bypass decoding of the syntax elements **coeff_sign_flag[]** and **coeff_abs_level_remaining[]**. **cabac_bypass_alignment_enabled_flag** equal to 0 specifies that no CABAC alignment process is used prior to bypass decoding. When not present, the value of **cabac_bypass_alignment_enabled_flag** is inferred to be equal to 0.

7.4.3.2.3 Sequence parameter set screen content coding extension semantics

sps_curr_pic_ref_enabled_flag equal to 1 specifies that a picture in the CVS may be included in a reference picture list of a slice of the picture itself. **sps_curr_pic_ref_enabled_flag** equal to 0 specifies that a picture in the CVS is never included

in a reference picture list of a slice of the picture itself. When not present, the value of `sps_curr_pic_ref_enabled_flag` is inferred to be equal to 0.

palette_mode_enabled_flag equal to 1 specifies that the decoding process for palette mode may be used for intra blocks. `palette_mode_enabled_flag` equal to 0 specifies that the decoding process for palette mode is not applied. When not present, the value of `palette_mode_enabled_flag` is inferred to be equal to 0.

palette_max_size specifies the maximum allowed palette size. When not present, the value of `palette_max_size` is inferred to be 0.

delta_palette_max_predictor_size specifies the difference between the maximum allowed palette predictor size and the maximum allowed palette size. When not present, the value of `delta_palette_max_predictor_size` is inferred to be 0. The variable `PaletteMaxPredictorSize` is derived as follows:

$$\text{PaletteMaxPredictorSize} = \text{palette_max_size} + \text{delta_palette_max_predictor_size} \quad (7-35)$$

It is a requirement of bitstream conformance that, when `palette_max_size` is equal to 0, the value of `delta_palette_max_predictor_size` shall be equal to 0.

sps_palette_predictor_initializers_present_flag equal to 1 specifies that the sequence palette predictors are initialized using the `sps_palette_predictor_initializers`. `sps_palette_predictor_initializers_present_flag` equal to 0 specifies that the entries in the sequence palette predictor are initialized to 0. When not present, the value of `sps_palette_predictor_initializers_present_flag` is inferred to be equal to 0.

It is a requirement of bitstream conformance that, when `palette_max_size` is equal to 0, the value of `sps_palette_predictor_initializers_present_flag` shall be equal to 0.

sps_num_palette_predictor_initializers_minus1 plus 1 specifies the number of entries in the sequence palette predictor initializer.

It is a requirement of bitstream conformance that the value of `sps_num_palette_predictor_initializers_minus1` plus 1 shall be less than or equal to `PaletteMaxPredictorSize`.

sps_palette_predictor_initializer[comp][i] specifies the value of the `comp`-th component of the `i`-th palette entry in the SPS that is used to initialize the array `PredictorPaletteEntries`. For values of `i` in the range of 0 to `sps_num_palette_predictor_initializers_minus1`, inclusive, the value of the `sps_palette_predictor_initializer[0][i]` shall be in the range of 0 to $(1 \ll \text{BitDepth}_Y) - 1$, inclusive, and the values of `sps_palette_predictor_initializer[1][i]` and `sps_palette_predictor_initializer[2][i]` shall be in the range of 0 to $(1 \ll \text{BitDepth}_C) - 1$, inclusive.

motion_vector_resolution_control_idc controls the presence and inference of the `use_integer_mv_flag` that specifies the resolution of motion vectors for inter prediction. The value of `motion_vector_resolution_control_idc` shall not be equal to 3 in bitstreams conforming to this version of this Specification. The value of 3 for `motion_vector_resolution_control_idc` is reserved for future use by ITU-T | ISO/IEC. When not present, the value of `motion_vector_resolution_control_idc` is inferred to be equal to 0.

intra_boundary_filtering_disabled_flag equal to 1 specifies that the intra boundary filtering process is unconditionally disabled for intra prediction. `intra_boundary_filtering_disabled_flag` equal to 0 specifies that the intra boundary filtering process may be used. When not present, the value of `intra_boundary_filtering_disabled_flag` is inferred to be equal to 0.

7.4.3.3 Picture parameter set RBSP semantics

7.4.3.3.1 General picture parameter set RBSP semantics

pps_pic_parameter_set_id identifies the PPS for reference by other syntax elements. The value of `pps_pic_parameter_set_id` shall be in the range of 0 to 63, inclusive.

pps_seq_parameter_set_id specifies the value of `sps_seq_parameter_set_id` for the active SPS. The value of `pps_seq_parameter_set_id` shall be in the range of 0 to 15, inclusive.

dependent_slice_segments_enabled_flag equal to 1 specifies the presence of the syntax element `dependent_slice_segment_flag` in the slice segment headers for coded pictures referring to the PPS. `dependent_slice_segments_enabled_flag` equal to 0 specifies the absence of the syntax element `dependent_slice_segment_flag` in the slice segment headers for coded pictures referring to the PPS.

output_flag_present_flag equal to 1 indicates that the `pic_output_flag` syntax element is present in the associated slice headers. `output_flag_present_flag` equal to 0 indicates that the `pic_output_flag` syntax element is not present in the associated slice headers.

num_extra_slice_header_bits specifies the number of extra slice header bits that are present in the slice header RBSP for coded pictures referring to the PPS. The value of `num_extra_slice_header_bits` shall be in the range of 0 to 2, inclusive, in

bitstreams conforming to this version of this Specification. Other values for `num_extra_slice_header_bits` are reserved for future use by ITU-T | ISO/IEC. However, decoders shall allow `num_extra_slice_header_bits` to have any value.

sign_data_hiding_enabled_flag equal to 0 specifies that sign bit hiding is disabled. `sign_data_hiding_enabled_flag` equal to 1 specifies that sign bit hiding is enabled.

cabac_init_present_flag equal to 1 specifies that `cabac_init_flag` is present in slice headers referring to the PPS. `cabac_init_present_flag` equal to 0 specifies that `cabac_init_flag` is not present in slice headers referring to the PPS.

num_ref_idx_l0_default_active_minus1 specifies the inferred value of `num_ref_idx_l0_active_minus1` for P and B slices with `num_ref_idx_active_override_flag` equal to 0. The value of `num_ref_idx_l0_default_active_minus1` shall be in the range of 0 to 14, inclusive.

num_ref_idx_l1_default_active_minus1 specifies the inferred value of `num_ref_idx_l1_active_minus1` for B slices with `num_ref_idx_active_override_flag` equal to 0. The value of `num_ref_idx_l1_default_active_minus1` shall be in the range of 0 to 14, inclusive.

init_qp_minus26 plus 26 specifies the initial value of `SliceQpY` for each slice referring to the PPS. The initial value of `SliceQpY` is modified at the slice segment layer when a non-zero value of `slice_qp_delta` is decoded. The value of `init_qp_minus26` shall be in the range of $-(26 + \text{QpBdOffset}_Y)$ to +25, inclusive.

constrained_intra_pred_flag equal to 0 specifies that intra prediction allows usage of residual data and decoded samples of neighbouring coding blocks coded using either intra or inter prediction modes. `constrained_intra_pred_flag` equal to 1 specifies constrained intra prediction, in which case intra prediction only uses residual data and decoded samples from neighbouring coding blocks coded using intra prediction modes.

NOTE 1 – Encoders that operate in error-prone environments should be designed with consideration of the potential for error propagation caused by references to other pictures and references to areas within the current picture that use other pictures as references.

transform_skip_enabled_flag equal to 1 specifies that `transform_skip_flag` may be present in the residual coding syntax. `transform_skip_enabled_flag` equal to 0 specifies that `transform_skip_flag` is not present in the residual coding syntax.

cu_qp_delta_enabled_flag equal to 1 specifies that the `diff_cu_qp_delta_depth` syntax element is present in the PPS and that `cu_qp_delta_abs` may be present in the transform unit syntax and the palette syntax. `cu_qp_delta_enabled_flag` equal to 0 specifies that the `diff_cu_qp_delta_depth` syntax element is not present in the PPS and that `cu_qp_delta_abs` is not present in the transform unit syntax and the palette syntax.

diff_cu_qp_delta_depth specifies the difference between the luma CTB size and the minimum luma coding block size of coding units that convey `cu_qp_delta_abs` and `cu_qp_delta_sign_flag`. The value of `diff_cu_qp_delta_depth` shall be in the range of 0 to $\log_2 \text{diff_max_min_luma_coding_block_size}$, inclusive. When not present, the value of `diff_cu_qp_delta_depth` is inferred to be equal to 0.

The variable `Log2MinCuQpDeltaSize` is derived as follows:

$$\text{Log2MinCuQpDeltaSize} = \text{CtbLog2Size}_Y - \text{diff_cu_qp_delta_depth} \quad (7-36)$$

pps_cb_qp_offset and **pps_cr_qp_offset** specify the offsets to the luma quantization parameter `Qp'Y` used for deriving `Qp'cb` and `Qp'cr`, respectively. The values of `pps_cb_qp_offset` and `pps_cr_qp_offset` shall be in the range of -12 to +12, inclusive. When `ChromaArrayType` is equal to 0, `pps_cb_qp_offset` and `pps_cr_qp_offset` are not used in the decoding process and decoders shall ignore their value.

pps_slice_chroma_qp_offsets_present_flag equal to 1 indicates that the `slice_cb_qp_offset` and `slice_cr_qp_offset` syntax elements are present in the associated slice headers. `pps_slice_chroma_qp_offsets_present_flag` equal to 0 indicates that these syntax elements are not present in the associated slice headers. When `ChromaArrayType` is equal to 0, `pps_slice_chroma_qp_offsets_present_flag` shall be equal to 0.

weighted_pred_flag equal to 0 specifies that weighted prediction is not applied to P slices. `weighted_pred_flag` equal to 1 specifies that weighted prediction is applied to P slices.

weighted_bipred_flag equal to 0 specifies that the default weighted prediction is applied to B slices. `weighted_bipred_flag` equal to 1 specifies that weighted prediction is applied to B slices.

transquant_bypass_enabled_flag equal to 1 specifies that `cu_transquant_bypass_flag` is present. `transquant_bypass_enabled_flag` equal to 0 specifies that `cu_transquant_bypass_flag` is not present.

tiles_enabled_flag equal to 1 specifies that there is more than one tile in each picture referring to the PPS. `tiles_enabled_flag` equal to 0 specifies that there is only one tile in each picture referring to the PPS.

It is a requirement of bitstream conformance that the value of `tiles_enabled_flag` shall be the same for all PPSs that are activated within a CVS.

entropy_coding_sync_enabled_flag equal to 1 specifies that a specific synchronization process for context variables, and when applicable, Rice parameter initialization states and palette predictor variables, is invoked before decoding the CTU which includes the first CTB of a row of CTBs in each tile in each picture referring to the PPS, and a specific storage process for context variables, and when applicable, Rice parameter initialization states and palette predictor variables, is invoked after decoding the CTU which includes the second CTB of a row of CTBs in each tile in each picture referring to the PPS. **entropy_coding_sync_enabled_flag** equal to 0 specifies that no specific synchronization process for context variables, and when applicable, Rice parameter initialization states and palette predictor variables, is required to be invoked before decoding the CTU which includes the first CTB of a row of CTBs in each tile in each picture referring to the PPS, and no specific storage process for context variables, and when applicable, Rice parameter initialization states and palette predictor variables, is required to be invoked after decoding the CTU which includes the second CTB of a row of CTBs in each tile in each picture referring to the PPS.

It is a requirement of bitstream conformance that the value of **entropy_coding_sync_enabled_flag** shall be the same for all PPSs that are activated within a CVS.

When **entropy_coding_sync_enabled_flag** is equal to 1 and the first CTB in a slice is not the first CTB of a row of CTBs in a tile, it is a requirement of bitstream conformance that the last CTB in the slice shall belong to the same row of CTBs as the first CTB in the slice.

When **entropy_coding_sync_enabled_flag** is equal to 1 and the first CTB in a slice segment is not the first CTB of a row of CTBs in a tile, it is a requirement of bitstream conformance that the last CTB in the slice segment shall belong to the same row of CTBs as the first CTB in the slice segment.

num_tile_columns_minus1 plus 1 specifies the number of tile columns partitioning the picture. **num_tile_columns_minus1** shall be in the range of 0 to $\text{PicWidthInCtbsY} - 1$, inclusive. When not present, the value of **num_tile_columns_minus1** is inferred to be equal to 0.

num_tile_rows_minus1 plus 1 specifies the number of tile rows partitioning the picture. **num_tile_rows_minus1** shall be in the range of 0 to $\text{PicHeightInCtbsY} - 1$, inclusive. When not present, the value of **num_tile_rows_minus1** is inferred to be equal to 0.

When **tiles_enabled_flag** is equal to 1, **num_tile_columns_minus1** and **num_tile_rows_minus1** shall not be both equal to 0.

uniform_spacing_flag equal to 1 specifies that tile column boundaries and likewise tile row boundaries are distributed uniformly across the picture. **uniform_spacing_flag** equal to 0 specifies that tile column boundaries and likewise tile row boundaries are not distributed uniformly across the picture but signalled explicitly using the syntax elements **column_width_minus1[i]** and **row_height_minus1[i]**. When not present, the value of **uniform_spacing_flag** is inferred to be equal to 1.

column_width_minus1[i] plus 1 specifies the width of the i-th tile column in units of CTBs.

row_height_minus1[i] plus 1 specifies the height of the i-th tile row in units of CTBs.

The following variables are derived by invoking the CTB raster and tile scanning conversion process as specified in clause 6.5.1:

- The list **CtbAddrRsToTs[ctbAddrRs]** for **ctbAddrRs** ranging from 0 to $\text{PicSizeInCtbsY} - 1$, inclusive, specifying the conversion from a CTB address in the CTB raster scan of a picture to a CTB address in the tile scan,
- the list **CtbAddrTsToRs[ctbAddrTs]** for **ctbAddrTs** ranging from 0 to $\text{PicSizeInCtbsY} - 1$, inclusive, specifying the conversion from a CTB address in the tile scan to a CTB address in the CTB raster scan of a picture,
- the list **TileId[ctbAddrTs]** for **ctbAddrTs** ranging from 0 to $\text{PicSizeInCtbsY} - 1$, inclusive, specifying the conversion from a CTB address in tile scan to a tile ID,
- the list **ColumnWidthInLumaSamples[i]** for **i** ranging from 0 to **num_tile_columns_minus1**, inclusive, specifying the width of the i-th tile column in units of luma samples,
- the list **RowHeightInLumaSamples[j]** for **j** ranging from 0 to **num_tile_rows_minus1**, inclusive, specifying the height of the j-th tile row in units of luma samples.

The values of **ColumnWidthInLumaSamples[i]** for **i** ranging from 0 to **num_tile_columns_minus1**, inclusive, and **RowHeightInLumaSamples[j]** for **j** ranging from 0 to **num_tile_rows_minus1**, inclusive, shall all be greater than 0.

The array **MinTbAddrZs** with elements **MinTbAddrZs[x][y]** for **x** ranging from 0 to $(\text{PicWidthInCtbsY} \ll (\text{CtbLog2SizeY} - \text{MinTbLog2SizeY})) - 1$, inclusive, and **y** ranging from 0 to $(\text{PicHeightInCtbsY} \ll (\text{CtbLog2SizeY} - \text{MinTbLog2SizeY})) - 1$, inclusive, specifying the conversion from a location (x, y) in units of minimum transform blocks to a transform block address in z-scan order, is derived by invoking the z-scan order array initialization process as specified in clause 6.5.2.

loop_filter_across_tiles_enabled_flag equal to 1 specifies that in-loop filtering operations may be performed across tile boundaries in pictures referring to the PPS. **loop_filter_across_tiles_enabled_flag** equal to 0 specifies that in-loop filtering

operations are not performed across tile boundaries in pictures referring to the PPS. The in-loop filtering operations include the deblocking filter and sample adaptive offset filter operations. When not present, the value of `loop_filter_across_tiles_enabled_flag` is inferred to be equal to 1.

pps_loop_filter_across_slices_enabled_flag equal to 1 specifies that in-loop filtering operations may be performed across left and upper boundaries of slices referring to the PPS. `pps_loop_filter_across_slices_enabled_flag` equal to 0 specifies that in-loop filtering operations are not performed across left and upper boundaries of slices referring to the PPS. The in-loop filtering operations include the deblocking filter and sample adaptive offset filter operations.

NOTE 2 – Loop filtering across slice boundaries can be enabled while loop filtering across tile boundaries is disabled and vice versa.

deblocking_filter_control_present_flag equal to 1 specifies the presence of deblocking filter control syntax elements in the PPS. `deblocking_filter_control_present_flag` equal to 0 specifies the absence of deblocking filter control syntax elements in the PPS.

deblocking_filter_override_enabled_flag equal to 1 specifies the presence of `deblocking_filter_override_flag` in the slice headers for pictures referring to the PPS. `deblocking_filter_override_enabled_flag` equal to 0 specifies the absence of `deblocking_filter_override_flag` in the slice headers for pictures referring to the PPS. When not present, the value of `deblocking_filter_override_enabled_flag` is inferred to be equal to 0.

pps_deblocking_filter_disabled_flag equal to 1 specifies that the operation of deblocking filter is not applied for slices referring to the PPS in which `slice_deblocking_filter_disabled_flag` is not present. `pps_deblocking_filter_disabled_flag` equal to 0 specifies that the operation of the deblocking filter is applied for slices referring to the PPS in which `slice_deblocking_filter_disabled_flag` is not present. When not present, the value of `pps_deblocking_filter_disabled_flag` is inferred to be equal to 0.

pps_beta_offset_div2 and **pps_tc_offset_div2** specify the default deblocking parameter offsets for β and tC (divided by 2) that are applied for slices referring to the PPS, unless the default deblocking parameter offsets are overridden by the deblocking parameter offsets present in the slice headers of the slices referring to the PPS. The values of `pps_beta_offset_div2` and `pps_tc_offset_div2` shall both be in the range of -6 to 6 , inclusive. When not present, the value of `pps_beta_offset_div2` and `pps_tc_offset_div2` are inferred to be equal to 0.

pps_scaling_list_data_present_flag equal to 1 specifies that the scaling list data used for the pictures referring to the PPS are derived based on the scaling lists specified by the active SPS and the scaling lists specified by the PPS. `pps_scaling_list_data_present_flag` equal to 0 specifies that the scaling list data used for the pictures referring to the PPS are inferred to be equal to those specified by the active SPS. When `scaling_list_enabled_flag` is equal to 0, the value of `pps_scaling_list_data_present_flag` shall be equal to 0. When `scaling_list_enabled_flag` is equal to 1, `sps_scaling_list_data_present_flag` is equal to 0 and `pps_scaling_list_data_present_flag` is equal to 0, the default scaling list data are used to derive the array `ScalingFactor` as described in the scaling list data semantics as specified in clause 7.4.5.

lists_modification_present_flag equal to 1 specifies that the syntax structure `ref_pic_lists_modification()` is present in the slice segment header. `lists_modification_present_flag` equal to 0 specifies that the syntax structure `ref_pic_lists_modification()` is not present in the slice segment header.

log2_parallel_merge_level_minus2 plus 2 specifies the value of the variable `Log2ParMrgLevel`, which is used in the derivation process for luma motion vectors for merge mode as specified in clause 8.5.3.2.2 and the derivation process for spatial merging candidates as specified in clause 8.5.3.2.3. The value of `log2_parallel_merge_level_minus2` shall be in the range of 0 to $CtbLog2SizeY - 2$, inclusive.

The variable `Log2ParMrgLevel` is derived as follows:

$$\text{Log2ParMrgLevel} = \text{log2_parallel_merge_level_minus2} + 2 \quad (7-37)$$

NOTE 3 – The value of `Log2ParMrgLevel` indicates the built-in capability of parallel derivation of the merging candidate lists. For example, when `Log2ParMrgLevel` is equal to 6, the merging candidate lists for all the prediction units (PUs) and coding units (CUs) contained in a 64×64 block can be derived in parallel.

slice_segment_header_extension_present_flag equal to 0 specifies that no slice segment header extension syntax elements are present in the slice segment headers for coded pictures referring to the PPS. `slice_segment_header_extension_present_flag` equal to 1 specifies that slice segment header extension syntax elements are present in the slice segment headers for coded pictures referring to the PPS.

pps_extension_present_flag equal to 1 specifies that the syntax elements `pps_range_extension_flag`, `pps_multilayer_extension_flag`, `pps_3d_extension_flag`, `pps_scc_extension_flag`, and `pps_extension_4bits` are present in the picture parameter set RBSP syntax structure. `pps_extension_present_flag` equal to 0 specifies that these syntax elements are not present.

pps_range_extension_flag equal to 1 specifies that the `pps_range_extension()` syntax structure is present in the PPS RBSP syntax structure. `pps_range_extension_flag` equal to 0 specifies that this syntax structure is not present. When not present, the value of `pps_range_extension_flag` is inferred to be equal to 0.

pps_multilayer_extension_flag equal to 1 specifies that the `pps_multilayer_extension()` syntax structure is present in the PPS RBSP syntax structure. `pps_multilayer_extension_flag` equal to 0 specifies that the `pps_multilayer_extension()` syntax structure is not present. When not present, the value of `pps_multilayer_extension_flag` is inferred to be equal to 0.

pps_3d_extension_flag equal to 1 specifies that the `pps_3d_extension()` syntax structure (specified in Annex I) is present in the PPS RBSP syntax structure. `pps_3d_extension_flag` equal to 0 specifies that the `pps_3d_extension()` syntax structure is not present. When not present, the value of `pps_3d_extension_flag` is inferred to be equal to 0.

pps_scc_extension_flag equal to 1 specifies that the `pps_scc_extension()` syntax structure is present in the PPS RBSP syntax structure. `pps_scc_extension_flag` equal to 0 specifies that this syntax structure is not present. When not present, the value of `pps_scc_extension_flag` is inferred to be equal to 0.

pps_extension_4bits equal to 0 specifies that no `pps_extension_data_flag` syntax elements are present in the PPS RBSP syntax structure. When present, `pps_extension_4bits` shall be equal to 0 in bitstreams conforming to this version of this Specification. Values of `pps_extension_4bits` not equal to 0 are reserved for future use by ITU-T | ISO/IEC. Decoders shall allow the value of `pps_extension_4bits` to be not equal to 0 and shall ignore all `pps_extension_data_flag` syntax elements in a PPS NAL unit. When not present, the value of `pps_extension_4bits` is inferred to be equal to 0.

pps_extension_data_flag may have any value. Its presence and value do not affect the decoding process specified in this version of this Specification. Decoders conforming to this version of this Specification shall ignore all `pps_extension_data_flag` syntax elements.

7.4.3.3.2 Picture parameter set range extension semantics

log2_max_transform_skip_block_size_minus2 plus 2 specifies the maximum transform block size for which `transform_skip_flag` may be present in coded pictures referring to the PPS. When not present, the value of `log2_max_transform_skip_block_size_minus2` is inferred to be equal to 0. When present, the value of `log2_max_transform_skip_block_size_minus2` shall be less than or equal to `MaxTbLog2SizeY - 2`.

The variable `Log2MaxTransformSkipSize` is derived as follows:

$$\text{Log2MaxTransformSkipSize} = \text{log2_max_transform_skip_block_size_minus2} + 2 \quad (7-38)$$

cross_component_prediction_enabled_flag equal to 1 specifies that `log2_res_scale_abs_plus1` and `res_scale_sign_flag` may be present in the transform unit syntax for pictures referring to the PPS. `cross_component_prediction_enabled_flag` equal to 0 specifies that `log2_res_scale_abs_plus1` and `res_scale_sign_flag` are not present for pictures referring to the PPS. When not present, the value of `cross_component_prediction_enabled_flag` is inferred to be equal to 0. When `ChromaArrayType` is not equal to 3, it is a requirement of bitstream conformance that the value of `cross_component_prediction_enabled_flag` shall be equal to 0.

chroma_qp_offset_list_enabled_flag equal to 1 specifies that the `cu_chroma_qp_offset_flag` may be present in the transform unit syntax. `chroma_qp_offset_list_enabled_flag` equal to 0 specifies that the `cu_chroma_qp_offset_flag` is not present in the transform unit syntax. When `ChromaArrayType` is equal to 0, it is a requirement of bitstream conformance that the value of `chroma_qp_offset_list_enabled_flag` shall be equal to 0.

diff_cu_chroma_qp_offset_depth specifies the difference between the luma CTB size and the minimum luma coding block size of coding units that convey `cu_chroma_qp_offset_flag`. The value of `diff_cu_chroma_qp_offset_depth` shall be in the range of 0 to `log2_diff_max_min_luma_coding_block_size`, inclusive.

The variable `Log2MinCuChromaQpOffsetSize` is derived as follows:

$$\text{Log2MinCuChromaQpOffsetSize} = \text{CtbLog2SizeY} - \text{diff_cu_chroma_qp_offset_depth} \quad (7-39)$$

chroma_qp_offset_list_len_minus1 plus 1 specifies the number of `cb_qp_offset_list[i]` and `cr_qp_offset_list[i]` syntax elements that are present in the PPS. The value of `chroma_qp_offset_list_len_minus1` shall be in the range of 0 to 5, inclusive.

cb_qp_offset_list[i] and **cr_qp_offset_list[i]** specify offsets used in the derivation of Qp'_{Cb} and Qp'_{Cr} , respectively. The values of `cb_qp_offset_list[i]` and `cr_qp_offset_list[i]` shall be in the range of -12 to +12, inclusive.

log2_sao_offset_scale_luma is the base 2 logarithm of the scaling parameter that is used to scale sample adaptive offset (SAO) offset values for luma samples. The value of `log2_sao_offset_scale_luma` shall be in the range of 0 to $\text{Max}(0, \text{BitDepth}_Y - 10)$, inclusive. When not present, the value of `log2_sao_offset_scale_luma` is inferred to be equal to 0.

log2_sao_offset_scale_chroma is the base 2 logarithm of the scaling parameter that is used to scale SAO offset values for chroma samples. The value of log2_sao_offset_scale_chroma shall be in the range of 0 to Max(0, BitDepth_C – 10), inclusive. When not present, the value of log2_sao_offset_scale_chroma is inferred to be equal to 0.

7.4.3.3.3 Picture parameter set screen content coding extension semantics

pps_curr_pic_ref_enabled_flag equal to 1 specifies that a picture referring to the PPS may be included in a reference picture list of a slice of the picture itself. pps_curr_pic_ref_enabled_flag equal to 0 specifies that a picture referring to the PPS is never included in a reference picture list of a slice of the picture itself. When not present, the value of pps_curr_pic_ref_enabled_flag is inferred to be equal to 0.

It is a requirement of bitstream conformance that when sps_curr_pic_ref_enabled_flag is equal to 0, the value of pps_curr_pic_ref_enabled_flag shall be equal to 0.

The variable TwoVersionsOfCurrDecPicFlag is derived as follows:

$$\text{TwoVersionsOfCurrDecPicFlag} = \text{pps_curr_pic_ref_enabled_flag} \ \&\& \\ (\text{sample_adaptive_offset_enabled_flag} \ || \ !\text{pps_deblocking_filter_disabled_flag} \ || \ \text{deblocking_filter_override_enabled_flag}) \quad (7-40)$$

When sps_max_dec_pic_buffering_minus1[TemporalId] is equal to 0, the value of TwoVersionsOfCurrDecPicFlag shall be equal to 0.

residual_adaptive_colour_transform_enabled_flag equal to 1 specifies that an adaptive colour transform may be applied to the residual in the decoding process. residual_adaptive_colour_transform_enabled_flag equal to 0 specifies that adaptive colour transform is not applied to the residual. When not present, the value of residual_adaptive_colour_transform_enabled_flag is inferred to be equal to 0.

When ChromaArrayType is not equal to 3, residual_adaptive_colour_transform_enabled_flag shall be equal to 0.

pps_slice_act_qp_offsets_present_flag equal to 1 specifies that slice_act_y_qp_offset, slice_act_cb_qp_offset, slice_act_cr_qp_offset are present in the slice header. pps_slice_act_qp_offsets_present_flag equal to 0 specifies that slice_act_y_qp_offset, slice_act_cb_qp_offset, slice_act_cr_qp_offset are not present in the slice header. When not present, the value of pps_slice_act_qp_offsets_present_flag is inferred to be equal to 0.

pps_act_y_qp_offset_plus5, **pps_act_cb_qp_offset_plus5** and **pps_act_cr_qp_offset_plus3** are used to determine the offsets that are applied to the quantization parameter values qP derived in clause 8.6.2 for the luma, Cb and Cr components, respectively, when tu_residual_act_flag[xTbY][yTbY] is equal to 1. When not present, the values of pps_act_y_qp_offset_plus5, pps_act_cb_qp_offset_plus5 and pps_act_cr_qp_offset_plus3 are inferred to be equal to 0.

The variable PpsActQpOffsetY is set equal to pps_act_y_qp_offset_plus5 – 5.

The variable PpsActQpOffsetCb is set equal to pps_act_cb_qp_offset_plus5 – 5.

The variable PpsActQpOffsetCr is set equal to pps_act_cr_qp_offset_plus3 – 3.

NOTE – The constant offset values of 5, 5, and 3 above are applied because the adaptive colour transformation that is applied to the residual when tu_residual_act_flag[xTbY][yTbY] is equal to 1 is not an orthonormal transformation.

It is a requirement of bitstream conformance that the values of PpsActQpOffsetY, PpsActQpOffsetCb, and PpsActQpOffsetCr shall be in the range of –12 to +12, inclusive.

pps_palette_predictor_initializers_present_flag equal to 1 specifies that the palette predictor initializers used for the pictures referring to the PPS are derived based on the palette predictor initializers specified by the PPS. pps_palette_predictor_initializer_flag equal to 0 specifies that the palette predictor initializers used for the pictures referring to the PPS are inferred to be equal to those specified by the active SPS. When not present, the value of pps_palette_predictor_initializers_present_flag is inferred to be equal to 0.

It is a requirement of bitstream conformance that the value of pps_palette_predictor_initializers_present_flag shall be equal to 0 when either palette_max_size is equal to 0 or palette_mode_enabled_flag is equal to 0.

pps_num_palette_predictor_initializers specifies the number of entries in the picture palette predictor initializer.

It is a requirement of bitstream conformance that the value of pps_num_palette_predictor_initializers shall be less than or equal to PaletteMaxPredictorSize.

monochrome_palette_flag equal to 1 specifies that the pictures that refer to this PPS are monochrome. monochrome_palette_flag equal to 0 specifies that the pictures that refer to this PPS have multiple components.

It is a requirement of bitstream conformance that the value of the monochrome_palette_flag shall be equal to (chroma_format_idc == 0).

luma_bit_depth_entry_minus8 plus 8 specifies the bit depth of the luma component of the entries of the palette predictor initializer. It is a requirement of bitstream conformance that the value of **luma_bit_depth_entry_minus8** shall be equal to the value of **bit_depth_luma_minus8**.

chroma_bit_depth_entry_minus8 plus 8 specifies the bit depth of the chroma components of the entries of the palette predictor initializer. It is a requirement of bitstream conformance that the value of **chroma_bit_depth_entry_minus8** shall be equal to the value of **bit_depth_chroma_minus8**.

pps_palette_predictor_initializer[comp][i] specifies the value of the comp-th component of the i-th palette entry in the PPS that is used to initialize the array **PredictorPaletteEntries**. For values of i in the range of 0 to **pps_num_palette_predictor_initializers** – 1, inclusive, the number of bits used to represent **pps_palette_predictor_initializer**[0][i] is **luma_bit_depth_entry_minus8** + 8, and the number of bits used to represent **pps_palette_predictor_initializer**[1][i] and **pps_palette_predictor_initializer**[2][i] is **chroma_bit_depth_entry_minus8** + 8.

7.4.3.4 Supplemental enhancement information RBSP semantics

Supplemental enhancement information (SEI) contains information that is not necessary to decode the samples of coded pictures from VCL NAL units. An SEI RBSP contains one or more SEI messages.

7.4.3.5 Access unit delimiter RBSP semantics

The access unit delimiter may be used to indicate the type of slices present in the coded pictures in the access unit containing the access unit delimiter NAL unit and to simplify the detection of the boundary between access units. There is no normative decoding process associated with the access unit delimiter.

pic_type indicates that the slice_type values for all slices of the coded pictures in the access unit containing the access unit delimiter NAL unit are members of the set listed in Table 7-2 for the given value of **pic_type**. The value of **pic_type** shall be equal to 0, 1 or 2 in bitstreams conforming to this version of this Specification. Other values of **pic_type** are reserved for future use by ITU-T | ISO/IEC. Decoders conforming to this version of this Specification shall ignore reserved values of **pic_type**.

Table 7-2 – Interpretation of **pic_type**

pic_type	slice_type values that may be present in the coded picture
0	I
1	P, I
2	B, P, I

7.4.3.6 End of sequence RBSP semantics

When included in a NAL unit with **nuh_layer_id** equal to 0, the end of sequence RBSP specifies that the current access unit is the last access unit in the coded video sequence in decoding order and the next subsequent access unit in the bitstream in decoding order (if any) is an IRAP access unit with **NoRaslOutputFlag** equal to 1. The syntax content of the SODB and RBSP for the end of sequence RBSP are empty.

7.4.3.7 End of bitstream RBSP semantics

The end of bitstream RBSP indicates that no additional NAL units are present in the bitstream that are subsequent to the end of bitstream RBSP in decoding order. The syntax content of the SODB and RBSP for the end of bitstream RBSP are empty.

NOTE – When an elementary stream contains more than one bitstream, the last NAL unit of the last access unit of a bitstream must contain an end of bitstream NAL unit and the first access unit of the subsequent bitstream must be an IRAP access unit. This IRAP access unit may be a CRA, BLA or IDR access unit.

7.4.3.8 Filler data RBSP semantics

The filler data RBSP contains bytes whose value shall be equal to 0xFF. No normative decoding process is specified for a filler data RBSP.

ff_byte is a byte equal to 0xFF.

7.4.3.9 Slice segment layer RBSP semantics

The slice segment layer RBSP consists of a slice segment header and slice segment data.

7.4.3.10 RBSP slice segment trailing bits semantics

cabac_zero_word is a byte-aligned sequence of two bytes equal to 0x0000.

Let **NumBytesInVclNalUnits** be the sum of the values of **NumBytesInNalUnit** for all VCL NAL units of a coded picture.

Let **BinCountsInNalUnits** be the number of times that the parsing process function **DecodeBin()**, specified in clause 9.3.4.3, is invoked to decode the contents of all VCL NAL units of a coded picture.

Let the variable **RawMinCuBits** be derived as follows:

$$\text{RawMinCuBits} = \text{MinCbSizeY} * \text{MinCbSizeY} * (\text{BitDepth}_Y + 2 * \text{BitDepth}_C / (\text{SubWidthC} * \text{SubHeightC})) \quad (7-41)$$

The value of **BinCountsInNalUnits** shall be less than or equal to $(32 \div 3) * \text{NumBytesInVclNalUnits} + (\text{RawMinCuBits} * \text{PicSizeInMinCbsY}) \div 32$.

NOTE – The constraint on the maximum number of bins resulting from decoding the contents of the coded slice segment NAL units can be met by inserting a number of **cabac_zero_word** syntax elements to increase the value of **NumBytesInVclNalUnits**. Each **cabac_zero_word** is represented in a NAL unit by the three-byte sequence 0x000003 (as a result of the constraints on NAL unit contents that result in requiring inclusion of an **emulation_prevention_three_byte** for each **cabac_zero_word**).

7.4.3.11 RBSP trailing bits semantics

rbstop_one_bit shall be equal to 1.

rbstop_alignment_zero_bit shall be equal to 0.

7.4.3.12 Byte alignment semantics

alignment_bit_equal_to_one shall be equal to 1.

alignment_bit_equal_to_zero shall be equal to 0.

7.4.4 Profile, tier and level semantics

general_profile_space specifies the context for the interpretation of **general_profile_idc** and **general_profile_compatibility_flag[j]** for all values of **j** in the range of 0 to 31, inclusive. The value of **general_profile_space** shall be equal to 0 in bitstreams conforming to this version of this Specification. Other values for **general_profile_space** are reserved for future use by ITU-T | ISO/IEC. Decoders shall ignore the CVS when **general_profile_space** is not equal to 0.

general_tier_flag specifies the tier context for the interpretation of **general_level_idc** as specified in Annex A.

general_profile_idc, when **general_profile_space** is equal to 0, indicates a profile to which the CVS conforms as specified in Annex A. Bitstreams shall not contain values of **general_profile_idc** other than those specified in Annex A. Other values of **general_profile_idc** are reserved for future use by ITU-T | ISO/IEC.

general_profile_compatibility_flag[j] equal to 1, when **general_profile_space** is equal to 0, indicates that the CVS conforms to the profile indicated by **general_profile_idc** equal to **j** as specified in Annex A. When **general_profile_space** is equal to 0, **general_profile_compatibility_flag[general_profile_idc]** shall be equal to 1. The value of **general_profile_compatibility_flag[j]** shall be equal to 0 for any value of **j** that is not specified as an allowed value of **general_profile_idc** in Annex A.

general_progressive_source_flag and **general_interlaced_source_flag** are interpreted as follows:

- If **general_progressive_source_flag** is equal to 1 and **general_interlaced_source_flag** is equal to 0, the source scan type of the pictures in the CVS should be interpreted as progressive only.
- Otherwise, if **general_progressive_source_flag** is equal to 0 and **general_interlaced_source_flag** is equal to 1, the source scan type of the pictures in the CVS should be interpreted as interlaced only.
- Otherwise, if **general_progressive_source_flag** is equal to 0 and **general_interlaced_source_flag** is equal to 0, the source scan type of the pictures in the CVS should be interpreted as unknown or unspecified.
- Otherwise (**general_progressive_source_flag** is equal to 1 and **general_interlaced_source_flag** is equal to 1), the source scan type of each picture in the CVS is indicated at the picture level using the syntax element **source_scan_type** in a picture timing SEI message.

NOTE 1 – Decoders may ignore the values of **general_progressive_source_flag** and **general_interlaced_source_flag** for purposes other than determining the value to be inferred for **frame_field_info_present_flag** when **vui_parameters_present_flag** is equal to 0, as there are no other decoding process requirements associated with the values of these flags. Moreover, the actual source scan type of the pictures is outside the scope of this Specification and the method by which the encoder selects the values of **general_progressive_source_flag** and **general_interlaced_source_flag** is unspecified.

general_non_packed_constraint_flag equal to 1 specifies that there are no frame packing arrangement SEI messages, segmented rectangular frame packing arrangement SEI messages, equirectangular projection SEI messages, or cubemap projection SEI messages present in the CVS. **general_non_packed_constraint_flag** equal to 0 indicates that there may or may not be one or more frame packing arrangement SEI messages, segmented rectangular frame packing arrangement SEI messages, equirectangular projection SEI messages, or cubemap projection SEI messages present in the CVS.

NOTE 2 – Decoders may ignore the value of **general_non_packed_constraint_flag**, as there are no decoding process requirements associated with the presence or interpretation of frame packing arrangement SEI messages, segmented rectangular frame packing arrangement SEI messages, equirectangular projection SEI messages, or cubemap projection SEI messages.

general_frame_only_constraint_flag equal to 1 specifies that **field_seq_flag** is equal to 0. **general_frame_only_constraint_flag** equal to 0 indicates that **field_seq_flag** may or may not be equal to 0.

NOTE 3 – Decoders may ignore the value of **general_frame_only_constraint_flag**, as there are no decoding process requirements associated with the value of **field_seq_flag**.

NOTE 4 – When **general_progressive_source_flag** is equal to 1, **general_frame_only_constraint_flag** may or may not be equal to 1.

general_max_12bit_constraint_flag, **general_max_10bit_constraint_flag**, **general_max_8bit_constraint_flag**, **general_max_422chroma_constraint_flag**, **general_max_420chroma_constraint_flag**, **general_max_monochrome_constraint_flag**, **general_intra_constraint_flag**, **general_one_picture_only_constraint_flag**, **general_lower_bit_rate_constraint_flag**, and **general_max_14bit_constraint_flag**, when present, have semantics specified in Annex A when the profile indicated by **general_profile_idc** or **general_profile_compatibility_flag[j]** is a profile specified in Annex A.

general_reserved_zero_33bits, when present, shall be equal to 0 in bitstreams conforming to this version of this Specification. Other values for **general_reserved_zero_33bits** are reserved for future use by ITU-T | ISO/IEC. Decoders shall ignore the value of **general_reserved_zero_33bits**.

general_reserved_zero_34bits, when present, shall be equal to 0 in bitstreams conforming to this version of this Specification. Other values for **general_reserved_zero_34bits** are reserved for future use by ITU-T | ISO/IEC. Decoders shall ignore the value of **general_reserved_zero_34bits**.

general_reserved_zero_7bits, when present, shall be equal to 0 in bitstreams conforming to this version of this Specification. Other values for **general_reserved_zero_7bits** are reserved for future use by ITU-T | ISO/IEC. Decoders shall ignore the value of **general_reserved_zero_7bits**.

general_reserved_zero_35bits, when present, shall be equal to 0 in bitstreams conforming to this version of this Specification. Other values for **general_reserved_zero_35bits** are reserved for future use by ITU-T | ISO/IEC. Decoders shall ignore the value of **general_reserved_zero_35bits**.

general_reserved_zero_43bits, when present, shall be equal to 0 in bitstreams conforming to this version of this Specification. Other values for **general_reserved_zero_43bits** are reserved for future use by ITU-T | ISO/IEC. Decoders shall ignore the value of **general_reserved_zero_43bits**.

general_inbld_flag equal to 1 specifies that the INBLD capability as specified in Annex F is required for decoding of the layer to which the **profile_tier_level()** syntax structure applies. **general_inbld_flag** equal to 0 specifies that the INBLD capability as specified in Annex F is not required for decoding of the layer to which the **profile_tier_level()** syntax structure applies. When **profilePresentFlag** is equal to 1, **general_profile_idc** is not equal to 9 or 11 and is not in the range of 1 to 5, inclusive, **general_profile_compatibility_flag[9]** is not equal to 1, **general_profile_compatibility_flag[11]** is not equal to 1, and **general_profile_compatibility_flag[j]** is not equal to 1 for any value of **j** in the range of 1 to 5, inclusive, the value of **general_inbld_flag** is inferred to be equal to 0.

general_reserved_zero_bit, when present, shall be equal to 0 in bitstreams conforming to this version of this Specification. The value 1 for **general_reserved_zero_1bit** is reserved for future use by ITU-T | ISO/IEC. Decoders shall ignore the value of **general_reserved_zero_bit**.

general_level_idc indicates a level to which the CVS conforms as specified in Annex A. Bitstreams shall not contain values of **general_level_idc** other than those specified in Annex A. Other values of **general_level_idc** are reserved for future use by ITU-T | ISO/IEC.

NOTE 5 – A greater value of **general_level_idc** indicates a higher level. The maximum level signalled in the VPS for a CVS may be higher than the level signalled in the SPS for the same CVS.

NOTE 6 – When the coded video sequence conforms to multiple profiles, **general_profile_idc** should indicate the profile that provides the preferred decoded result or the preferred bitstream identification, as determined by the encoder (in a manner not specified in this Specification).

NOTE 7 – The syntax elements **general_reserved_zero_33bits**, **general_reserved_zero_34bits** and **general_reserved_zero_43bits** may be used in future versions of this Specification to indicate further constraints on the bitstream (e.g., that a particular syntax combination that would otherwise be permitted by the indicated values of **general_profile_compatibility_flag[j]**, is not used).

sub_layer_profile_present_flag[i] equal to 1, specifies that profile information is present in the **profile_tier_level()** syntax structure for the sub-layer representation with **TemporalId** equal to **i**. **sub_layer_profile_present_flag[i]** equal to 0

specifies that profile information is not present in the `profile_tier_level()` syntax structure for the sub-layer representation with `TemporalId` equal to `i`. When `profilePresentFlag` is equal to 0, `sub_layer_profile_present_flag[i]` shall be equal to 0.

`sub_layer_level_present_flag[i]` equal to 1 specifies that level information is present in the `profile_tier_level()` syntax structure for the sub-layer representation with `TemporalId` equal to `i`. `sub_layer_level_present_flag[i]` equal to 0 specifies that level information is not present in the `profile_tier_level()` syntax structure for the sub-layer representation with `TemporalId` equal to `i`.

`reserved_zero_2bits[i]` shall be equal to 0 in bitstreams conforming to this version of this Specification. Other values for `reserved_zero_2bits[i]` are reserved for future use by ITU-T | ISO/IEC. Decoders shall ignore the value of `reserved_zero_2bits[i]`.

Each of the following syntax elements:

- `sub_layer_profile_space[i]`,
- `sub_layer_tier_flag[i]`,
- `sub_layer_profile_idc[i]`,
- `sub_layer_profile_compatibility_flag[i][j]`,
- `sub_layer_progressive_source_flag[i]`,
- `sub_layer_interlaced_source_flag[i]`,
- `sub_layer_non_packed_constraint_flag[i]`,
- `sub_layer_frame_only_constraint_flag[i]`,
- `sub_layer_max_12bit_constraint_flag[i]`,
- `sub_layer_max_10bit_constraint_flag[i]`,
- `sub_layer_max_8bit_constraint_flag[i]`,
- `sub_layer_max_422chroma_constraint_flag[i]`,
- `sub_layer_max_420chroma_constraint_flag[i]`,
- `sub_layer_max_monochrome_constraint_flag[i]`,
- `sub_layer_intra_constraint_flag[i]`,
- `sub_layer_one_picture_only_constraint_flag[i]`,
- `sub_layer_lower_bit_rate_constraint_flag[i]`,
- `sub_layer_max_14bit_constraint_flag[i]`,
- `sub_layer_reserved_zero_33bits[i]`,
- `sub_layer_reserved_zero_34bits[i]`,
- `sub_layer_reserved_zero_7bits[i]`,
- `sub_layer_reserved_zero_35bits[i]`,
- `sub_layer_reserved_zero_43bits[i]`,
- `sub_layer_inbld_flag[i]`,
- `sub_layer_reserved_zero_bit[i]`, and
- `sub_layer_level_idc[i]`,

is referred to as the `i`-th corresponding sub-layer syntax element of each of the following syntax elements:

- `general_profile_space`,
- `general_tier_flag`,
- `general_profile_idc`,
- `general_profile_compatibility_flag[j]`,
- `general_progressive_source_flag`,
- `general_interlaced_source_flag`,
- `general_non_packed_constraint_flag`,
- `general_frame_only_constraint_flag`,
- `general_max_12bit_constraint_flag`,
- `general_max_10bit_constraint_flag`,

- `general_max_8bit_constraint_flag`,
- `general_max_422chroma_constraint_flag`,
- `general_max_420chroma_constraint_flag`,
- `general_max_monochrome_constraint_flag`,
- `general_intra_constraint_flag`,
- `general_one_picture_only_constraint_flag`,
- `general_lower_bit_rate_constraint_flag`,
- `general_max_14bit_constraint_flag`,
- `general_reserved_zero_33bits`,
- `general_reserved_zero_34bits`,
- `general_reserved_zero_7bits`,
- `general_reserved_zero_35bits`,
- `general_reserved_zero_43bits`,
- `general_inbld_flag`,
- `general_reserved_zero_bit`, and
- `general_level_idc`,

respectively.

The semantics of a particular syntax element's i -th corresponding sub-layer syntax element, apart from the specification of the inference of the value when not present, is the same as for the particular syntax element, but applies to the sub-layer representation with `TemporalId` equal to i .

When not present, the value of `sub_layer_tier_flag[i]` is inferred to be equal to 0.

NOTE 8 – It is possible that `sub_layer_tier_flag[i]` is not present and `sub_layer_level_idc[i]` is present. In this case, a default value of `sub_layer_tier_flag[i]` is needed for interpretation of `sub_layer_level_idc[i]`.

When the `profile_tier_level()` syntax structure is included in an SPS or is the first `profile_tier_level()` syntax structure in a VPS, and any of the syntax elements `sub_layer_profile_space[i]`, `sub_layer_profile_idc[i]`, `sub_layer_profile_compatibility_flag[i][j]`, `sub_layer_progressive_source_flag[i]`, `sub_layer_interlaced_source_flag[i]`, `sub_layer_non_packed_constraint_flag[i]`, `sub_layer_frame_only_constraint_flag[i]`, `sub_layer_max_12bit_constraint_flag[i]`, `sub_layer_max_10bit_constraint_flag[i]`, `sub_layer_max_8bit_constraint_flag[i]`, `sub_layer_max_422chroma_constraint_flag[i]`, `sub_layer_max_420chroma_constraint_flag[i]`, `sub_layer_max_monochrome_constraint_flag[i]`, `sub_layer_intra_constraint_flag[i]`, `sub_layer_one_picture_only_constraint_flag[i]`, `sub_layer_lower_bit_rate_constraint_flag[i]`, `sub_layer_max_14bit_constraint_flag`, `sub_layer_reserved_zero_33bits[i]`, `sub_layer_reserved_zero_34bits[i]`, `sub_layer_reserved_zero_43bits[i]`, `sub_layer_inbld_flag[i]`, `sub_layer_reserved_zero_1bit[i]` and `sub_layer_level_idc[i]` is not present for any value of i in the range of 0 to `maxNumSubLayersMinus1 – 1`, inclusive, in the `profile_tier_level()` syntax structure, the value of the syntax element is inferred as follows (in decreasing order of i values from `maxNumSubLayersMinus1 – 1` to 0):

- If the value of i is equal to `maxNumSubLayersMinus1`, the value of the syntax element is inferred to be equal to the value of the corresponding syntax element prefixed with "general_" of the same `profile_tier_level()` syntax structure.

NOTE 9 – For example, in this case, if `sub_layer_profile_space[i]` is not present, the value is inferred to be equal to `general_profile_space` of the same `profile_tier_level()` syntax structure.

- Otherwise (the value of i is less than `maxNumSubLayersMinus1`), the value of the syntax element is inferred to be equal to the corresponding syntax element with i being replaced with $i + 1$ of the same `profile_tier_level()` syntax structure.

NOTE 10 – For example, in this case, if `sub_layer_profile_space[i]` is not present, the value is inferred to be equal to `sub_layer_profile_space[i + 1]` of the same `profile_tier_level()` syntax structure.

7.4.5 Scaling list data semantics

`scaling_list_pred_mode_flag[sizeId][matrixId]` equal to 0 specifies that the values of the scaling list are the same as the values of a reference scaling list. The reference scaling list is specified by `scaling_list_pred_matrix_id_delta[sizeId][matrixId]`. `scaling_list_pred_mode_flag[sizeId][matrixId]` equal to 1 specifies that the values of the scaling list are explicitly signalled.

`scaling_list_pred_matrix_id_delta[sizeId][matrixId]` specifies the reference scaling list used to derive `ScalingList[sizeId][matrixId]` as follows:

- If `scaling_list_pred_matrix_id_delta[sizeId][matrixId]` is equal to 0, the scaling list is inferred from the default scaling list `ScalingList[sizeId][matrixId][i]` as specified in Table 7-5 and Table 7-6 for $i = 0..Min(63, (1 \ll (4 + (sizeId \ll 1))) - 1)$.
- Otherwise, the scaling list is inferred from the reference scaling list as follows:

$$\text{refMatrixId} = \text{matrixId} - \text{scaling_list_pred_matrix_id_delta}[\text{sizeId}][\text{matrixId}] * (\text{sizeId} == 3 ? 3 : 1) \quad (7-42)$$

$$\text{ScalingList}[\text{sizeId}][\text{matrixId}][i] = \text{ScalingList}[\text{sizeId}][\text{refMatrixId}][i]$$

with $i = 0..Min(63, (1 \ll (4 + (sizeId \ll 1))) - 1)$ (7-43)

If `sizeId` is less than or equal to 2, the value of `scaling_list_pred_matrix_id_delta[sizeId][matrixId]` shall be in the range of 0 to `matrixId`, inclusive. Otherwise (`sizeId` is equal to 3), the value of `scaling_list_pred_matrix_id_delta[sizeId][matrixId]` shall be in the range of 0 to `matrixId / 3`, inclusive.

Table 7-3 – Specification of sizeId

Size of quantization matrix	sizeId
4x4	0
8x8	1
16x16	2
32x32	3

Table 7-4 – Specification of matrixId according to sizeId, prediction mode and colour component

sizeId	CuPredMode	cIdx (Colour component)	matrixId
0, 1, 2, 3	MODE_INTRA	0 (Y)	0
0, 1, 2, 3	MODE_INTRA	1 (Cb)	1
0, 1, 2, 3	MODE_INTRA	2 (Cr)	2
0, 1, 2, 3	MODE_INTER	0 (Y)	3
0, 1, 2, 3	MODE_INTER	1 (Cb)	4
0, 1, 2, 3	MODE_INTER	2 (Cr)	5

`scaling_list_dc_coef_minus8[sizeId - 2][matrixId]` plus 8 specifies the value of the variable `ScalingFactor[2][matrixId][0][0]` for the scaling list for the 16x16 size when `sizeId` is equal to 2 and specifies the value of `ScalingFactor[3][matrixId][0][0]` for the scaling list for the 32x32 size when `sizeId` is equal to 3. The value of `scaling_list_dc_coef_minus8[sizeId - 2][matrixId]` shall be in the range of -7 to 247, inclusive.

When `scaling_list_pred_mode_flag[sizeId][matrixId]` is equal to 0, `scaling_list_pred_matrix_id_delta[sizeId][matrixId]` is equal to 0 and `sizeId` is greater than 1, the value of `scaling_list_dc_coef_minus8[sizeId - 2][matrixId]` is inferred to be equal to 8.

When `scaling_list_pred_matrix_id_delta[sizeId][matrixId]` is not equal to 0 and `sizeId` is greater than 1, the value of `scaling_list_dc_coef_minus8[sizeId - 2][matrixId]` is inferred to be equal to `scaling_list_dc_coef_minus8[sizeId - 2][refMatrixId]`, where the value of `refMatrixId` is given by Equation 7-42.

`scaling_list_delta_coef` specifies the difference between the current matrix coefficient `ScalingList[sizeId][matrixId][i]` and the previous matrix coefficient `ScalingList[sizeId][matrixId][i - 1]`, when `scaling_list_pred_mode_flag[sizeId][matrixId]` is equal to 1. The value of `scaling_list_delta_coef` shall be in the range of -128 to 127, inclusive. The value of `ScalingList[sizeId][matrixId][i]` shall be greater than 0.

Table 7-5 – Specification of default values of ScalingList[0][matrixId][i] with i = 0..15

i	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
ScalingList[0][0..5][i]	16	16	16	16	16	16	16	16	16	16	16	16	16	16	16	16

Table 7-6 – Specification of default values of ScalingList[1..3][matrixId][i] with i = 0..63

i	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
ScalingList[1..3][0..2][i]	16	16	16	16	16	16	16	16	16	16	17	16	17	16	17	18
ScalingList[1..3][3..5][i]	16	16	16	16	16	16	16	16	16	16	17	17	17	17	17	18
i – 16	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
ScalingList[1..3][0..2][i]	17	18	18	17	18	21	19	20	21	20	19	21	24	22	22	24
ScalingList[1..3][3..5][i]	18	18	18	18	18	20	20	20	20	20	20	20	24	24	24	24
i – 32	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

i – 48	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
ScalingList[1..3][0..2][i]	29	36	41	44	41	36	47	54	54	47	65	70	65	88	88	115
ScalingList[1..3][3..5][i]	28	33	33	33	33	33	41	41	41	41	54	54	54	71	71	91

The four-dimensional array ScalingFactor[sizeId][matrixId][x][y], with $x, y = 0..(1 \ll (2 + \text{sizeId})) - 1$, specifies the array of scaling factors according to the variables sizeId specified in Table 7-3 and matrixId specified in Table 7-4.

The elements of the quantization matrix of size 4x4, ScalingFactor[0][matrixId][][], are derived as follows:

$$\text{ScalingFactor}[0][\text{matrixId}][x][y] = \text{ScalingList}[0][\text{matrixId}][i] \quad (7-44)$$

with $i = 0..15$, $\text{matrixId} = 0..5$, $x = \text{ScanOrder}[2][0][i][0]$, and $y = \text{ScanOrder}[2][0][i][1]$

The elements of the quantization matrix of size 8x8, ScalingFactor[1][matrixId][][], are derived as follows:

$$\text{ScalingFactor}[1][\text{matrixId}][x][y] = \text{ScalingList}[1][\text{matrixId}][i] \quad (7-45)$$

with $i = 0..63$, $\text{matrixId} = 0..5$, $x = \text{ScanOrder}[3][0][i][0]$, and $y = \text{ScanOrder}[3][0][i][1]$

The elements of the quantization matrix of size 16x16, ScalingFactor[2][matrixId][][], are derived as follows:

$$\text{ScalingFactor}[2][\text{matrixId}][x * 2 + k][y * 2 + j] = \text{ScalingList}[2][\text{matrixId}][i] \quad (7-46)$$

with $i = 0..63$, $j = 0..1$, $k = 0..1$, $\text{matrixId} = 0..5$, $x = \text{ScanOrder}[3][0][i][0]$, and $y = \text{ScanOrder}[3][0][i][1]$

$$\text{ScalingFactor}[2][\text{matrixId}][0][0] = \text{scaling_list_dc_coef_minus8}[0][\text{matrixId}] + 8 \quad (7-47)$$

with $\text{matrixId} = 0..5$

The elements of the quantization matrix of size 32x32, ScalingFactor[3][matrixId][][], are derived as follows:

$$\text{ScalingFactor}[3][\text{matrixId}][x * 4 + k][y * 4 + j] = \text{ScalingList}[3][\text{matrixId}][i] \quad (7-48)$$

with $i = 0..63$, $j = 0..3$, $k = 0..3$, $\text{matrixId} = 0, 3$, $x = \text{ScanOrder}[3][0][i][0]$, and $y = \text{ScanOrder}[3][0][i][1]$

$$\text{ScalingFactor}[3][\text{matrixId}][0][0] = \text{scaling_list_dc_coef_minus8}[1][\text{matrixId}] + 8 \quad (7-49)$$

with $\text{matrixId} = 0, 3$

When ChromaArrayType is equal to 3, the elements of the chroma quantization matrix of size 32x32, ScalingFactor[3][matrixId][][], with $\text{matrixId} = 1, 2, 4$ and 5 are derived as follows:

$$\text{ScalingFactor}[3][\text{matrixId}][x * 4 + k][y * 4 + j] = \text{ScalingList}[2][\text{matrixId}][i] \quad (7-50)$$

with $i = 0..63$, $j = 0..3$, $k = 0..3$, $x = \text{ScanOrder}[3][0][i][0]$, and $y = \text{ScanOrder}[3][0][i][1]$

$$\text{ScalingFactor}[3][\text{matrixId}][0][0] = \text{scaling_list_dc_coef_minus8}[0][\text{matrixId}] + 8 \quad (7-51)$$

7.4.6 Supplemental enhancement information message semantics

Each SEI message consists of the variables specifying the type `payloadType` and size `payloadSize` of the SEI message payload. SEI message payloads are specified in Annex D. The derived SEI message payload size `payloadSize` is specified in bytes and shall be equal to the number of RBSP bytes in the SEI message payload.

NOTE – The NAL unit byte sequence containing the SEI message might include one or more emulation prevention bytes (represented by `emulation_prevention_three_byte` syntax elements). Since the payload size of an SEI message is specified in RBSP bytes, the quantity of emulation prevention bytes is not included in the size `payloadSize` of an SEI payload.

ff_byte is a byte equal to 0xFF identifying a need for a longer representation of the syntax structure that it is used within.

last_payload_type_byte is the last byte of the payload type of an SEI message.

last_payload_size_byte is the last byte of the payload size of an SEI message.

7.4.7 Slice segment header semantics

7.4.7.1 General slice segment header semantics

When present, the value of the slice segment header syntax elements `slice_pic_parameter_set_id`, `pic_output_flag`, `no_output_of_prior_pics_flag`, `slice_pic_order_cnt_lsb`, `short_term_ref_pic_set_sps_flag`, `short_term_ref_pic_set_idx`, `num_long_term_sps`, `num_long_term_pics` and `slice_temporal_mvp_enabled_flag` shall be the same in all slice segment headers of a coded picture. When present, the value of the slice segment header syntax elements `lt_idx_sps[i]`, `poc_lsb_lt[i]`, `used_by_curr_pic_lt_flag[i]`, `delta_poc_msb_present_flag[i]` and `delta_poc_msb_cycle_lt[i]` shall be the same in all slice segment headers of a coded picture for each possible value of *i*.

first_slice_segment_in_pic_flag equal to 1 specifies that the slice segment is the first slice segment of the picture in decoding order. **first_slice_segment_in_pic_flag** equal to 0 specifies that the slice segment is not the first slice segment of the picture in decoding order.

NOTE 1 – This syntax element may be used for detection of the boundary between coded pictures that are consecutive in decoding order. However, when IDR pictures are consecutive in decoding order and have the same NAL unit type, loss of the first slice of an IDR picture can cause a problem with detection of the boundary between the coded pictures. This can occur, e.g., in the transmission of all-intra-coded video in an error-prone environment. This problem can be mitigated by alternately using the two different IDR NAL unit types (IDR_W_RADL and IDR_N_LP) for any two consecutive IDR pictures. The use of the temporal sub-layer zero index SEI message can also be helpful, as that SEI message includes the syntax element `irap_pic_id`, the value of which is different for IRAP pictures that are consecutive in decoding order. Some system environments have other provisions that can be helpful for picture boundary detection as well, such as the use of presentation timestamps in Rec. ITU-T H.222.0 | ISO/IEC 13818-1 systems, access unit framing in the ISO/IEC 14496-12 ISO base media file format, or the marker bit in IETF RFC 3550 real-time transport protocol headers.

no_output_of_prior_pics_flag affects the output of previously-decoded pictures in the decoded picture buffer after the decoding of an IDR or a BLA picture that is not the first picture in the bitstream as specified in Annex C.

slice_pic_parameter_set_id specifies the value of `pps_pic_parameter_set_id` for the PPS in use. The value of `slice_pic_parameter_set_id` shall be in the range of 0 to 63, inclusive.

Let `activePPS` be the PPS that has `pps_pic_parameter_set_id` equal to `slice_pic_parameter_set_id`, and let `activeSPS` be the SPS that has `sps_seq_parameter_set_id` equal to `pps_seq_parameter_set_id` of `activePPS`. It is a requirement of bitstream conformance that the following constraints apply:

- The value of `TemporalId` of `activePPS` shall be less than or equal to the value of `TemporalId` of the current picture.
- The value of `nuh_layer_id` of `activePPS` shall be less than or equal to the value of `nuh_layer_id` of the current picture.
- The value of `nuh_layer_id` of `activeSPS` shall be less than or equal to the value of `nuh_layer_id` of the current picture.

dependent_slice_segment_flag equal to 1 specifies that the value of each slice segment header syntax element that is not present is inferred to be equal to the value of the corresponding slice segment header syntax element in the slice header. When not present, the value of `dependent_slice_segment_flag` is inferred to be equal to 0.

The variable `SliceAddrRs` is derived as follows:

- If `dependent_slice_segment_flag` is equal to 0, `SliceAddrRs` is set equal to `slice_segment_address`.
- Otherwise, `SliceAddrRs` is set equal to `SliceAddrRs` of the preceding slice segment containing the CTB for which the CTB address is `CtbAddrTsToRs[CtbAddrRsToTs[slice_segment_address] – 1]`.

slice_segment_address specifies the address of the first CTB in the slice segment, in CTB raster scan of a picture. The length of the `slice_segment_address` syntax element is $\text{Ceil}(\text{Log}_2(\text{PicSizeInCtbsY}))$ bits. The value of

slice_segment_address shall be in the range of 0 to PicSizeInCtbsY – 1, inclusive, and the value of slice_segment_address shall not be equal to the value of slice_segment_address of any other coded slice segment NAL unit of the same coded picture. When slice_segment_address is not present, it is inferred to be equal to 0.

The variable CtbAddrInRs, specifying a CTB address in CTB raster scan of a picture, is set equal to slice_segment_address. The variable CtbAddrInTs, specifying a CTB address in tile scan, is set equal to CtbAddrRsToTs[CtbAddrInRs]. The variables CuQpOffsetCb and CuQpOffsetCr, specifying values to be used when determining the respective values of the Qp'Cb and Qp'Cr quantization parameters for the coding unit containing cu_chroma_qp_offset_flag, are both set equal to 0.

slice_reserved_flag[i] has semantics and values that are reserved for future use by ITU-T | ISO/IEC. Decoders shall ignore the presence and value of slice_reserved_flag[i].

slice_type specifies the coding type of the slice according to Table 7-7.

Table 7-7 – Name association to slice_type

slice_type	Name of slice_type
0	B (B slice)
1	P (P slice)
2	I (I slice)

When nal_unit_type has a value in the range of BLA_W_LP to RSV_IRAP_VCL23, inclusive, i.e., the picture is an IRAP picture, nuh_layer_id is equal to 0, and pps_curr_pic_ref_enabled_flag is equal to 0, slice_type shall be equal to 2.

When sps_max_dec_pic_buffering_minus1[TemporalId] is equal to 0, nuh_layer_id is equal to 0, and pps_curr_pic_ref_enabled_flag is equal to 0, slice_type shall be equal to 2.

pic_output_flag affects the decoded picture output and removal processes as specified in Annex C. When pic_output_flag is not present, it is inferred to be equal to 1.

colour_plane_id specifies the colour plane associated with the current slice RBSP when separate_colour_plane_flag is equal to 1. The value of colour_plane_id shall be in the range of 0 to 2, inclusive. colour_plane_id values 0, 1 and 2 correspond to the Y, Cb and Cr planes, respectively.

NOTE 2 – There is no dependency between the decoding processes of pictures having different values of colour_plane_id.

slice_pic_order_cnt_lsb specifies the picture order count modulo MaxPicOrderCntLsb for the current picture. The length of the slice_pic_order_cnt_lsb syntax element is log2_max_pic_order_cnt_lsb_minus4 + 4 bits. The value of the slice_pic_order_cnt_lsb shall be in the range of 0 to MaxPicOrderCntLsb – 1, inclusive. When slice_pic_order_cnt_lsb is not present, slice_pic_order_cnt_lsb is inferred to be equal to 0, except as specified in clause 8.3.3.1.

short_term_ref_pic_set_sps_flag equal to 1 specifies that the short-term RPS of the current picture is derived based on one of the st_ref_pic_set() syntax structures in the active SPS that is identified by the syntax element short_term_ref_pic_set_idx in the slice header. short_term_ref_pic_set_sps_flag equal to 0 specifies that the short-term RPS of the current picture is derived based on the st_ref_pic_set() syntax structure that is directly included in the slice headers of the current picture. When num_short_term_ref_pic_sets is equal to 0, the value of short_term_ref_pic_set_sps_flag shall be equal to 0.

short_term_ref_pic_set_idx specifies the index, into the list of the st_ref_pic_set() syntax structures included in the active SPS, of the st_ref_pic_set() syntax structure that is used for derivation of the short-term RPS of the current picture. The syntax element short_term_ref_pic_set_idx is represented by Ceil(Log2(num_short_term_ref_pic_sets)) bits. When not present, the value of short_term_ref_pic_set_idx is inferred to be equal to 0. The value of short_term_ref_pic_set_idx shall be in the range of 0 to num_short_term_ref_pic_sets – 1, inclusive.

The variable CurrRpsIdx is derived as follows:

- If short_term_ref_pic_set_sps_flag is equal to 1, CurrRpsIdx is set equal to short_term_ref_pic_set_idx.
- Otherwise, CurrRpsIdx is set equal to num_short_term_ref_pic_sets.

num_long_term_sps specifies the number of entries in the long-term RPS of the current picture that are derived based on the candidate long-term reference pictures specified in the active SPS. The value of num_long_term_sps shall be in the range of 0 to num_long_term_ref_pics_sps, inclusive. When not present, the value of num_long_term_sps is inferred to be equal to 0.

num_long_term_pics specifies the number of entries in the long-term RPS of the current picture that are directly signalled in the slice header. When not present, the value of num_long_term_pics is inferred to be equal to 0.

When `nuh_layer_id` is equal to 0, the value of `num_long_term_pics` shall be less than or equal to `sps_max_dec_pic_buffering_minus1[TemporalId] – NumNegativePics[CurrRpsIdx] – NumPositivePics[CurrRpsIdx] – num_long_term_sps – TwoVersionsOfCurrDecPicFlag`.

`lt_idx_sps[i]` specifies an index, into the list of candidate long-term reference pictures specified in the active SPS, of the *i*-th entry in the long-term RPS of the current picture. The number of bits used to represent `lt_idx_sps[i]` is equal to $\text{Ceil}(\text{Log2}(\text{num_long_term_ref_pics_sps}))$. When not present, the value of `lt_idx_sps[i]` is inferred to be equal to 0. The value of `lt_idx_sps[i]` shall be in the range of 0 to `num_long_term_ref_pics_sps – 1`, inclusive.

`poc_lsb_lt[i]` specifies the value of the picture order count modulo `MaxPicOrderCntLsb` of the *i*-th entry in the long-term RPS of the current picture. The length of the `poc_lsb_lt[i]` syntax element is $\text{log2_max_pic_order_cnt_lsb_minus4} + 4$ bits.

`used_by_curr_pic_lt_flag[i]` equal to 0 specifies that the *i*-th entry in the long-term RPS of the current picture is not used for reference by the current picture.

The variables `PocLsbLt[i]` and `UsedByCurrPicLt[i]` are derived as follows:

- If *i* is less than `num_long_term_sps`, `PocLsbLt[i]` is set equal to `lt_ref_pic_poc_lsb_sps[lt_idx_sps[i]]` and `UsedByCurrPicLt[i]` is set equal to `used_by_curr_pic_lt_sps_flag[lt_idx_sps[i]]`.
- Otherwise, `PocLsbLt[i]` is set equal to `poc_lsb_lt[i]` and `UsedByCurrPicLt[i]` is set equal to `used_by_curr_pic_lt_flag[i]`.

`delta_poc_msb_present_flag[i]` equal to 1 specifies that `delta_poc_msb_cycle_lt[i]` is present. `delta_poc_msb_present_flag[i]` equal to 0 specifies that `delta_poc_msb_cycle_lt[i]` is not present.

Let `prevTid0Pic` be the previous picture in decoding order that has `TemporalId` equal to 0 and is not a RASL, RADL or SLNR picture. Let `setOfPrevPocVals` be a set consisting of the following:

- the `PicOrderCntVal` of `prevTid0Pic`,
- the `PicOrderCntVal` of each picture in the RPS of `prevTid0Pic`,
- the `PicOrderCntVal` of each picture that follows `prevTid0Pic` in decoding order and precedes the current picture in decoding order.

When there is more than one value in `setOfPrevPocVals` for which the value modulo `MaxPicOrderCntLsb` is equal to `PocLsbLt[i]`, `delta_poc_msb_present_flag[i]` shall be equal to 1.

`delta_poc_msb_cycle_lt[i]` is used to determine the value of the most significant bits of the picture order count value of the *i*-th entry in the long-term RPS of the current picture. The value of `delta_poc_msb_cycle_lt[i]` shall be in the range of 0 to $2^{(32 - \text{log2_max_pic_order_cnt_lsb_minus4} - 4)}$, inclusive. When `delta_poc_msb_cycle_lt[i]` is not present, it is inferred to be equal to 0.

The variable `DeltaPocMsbCycleLt[i]` is derived as follows:

$$\begin{aligned} &\text{if}(i == 0 \mid \mid i == \text{num_long_term_sps}) \\ &\quad \text{DeltaPocMsbCycleLt}[i] = \text{delta_poc_msb_cycle_lt}[i] \\ &\text{else} \\ &\quad \text{DeltaPocMsbCycleLt}[i] = \text{delta_poc_msb_cycle_lt}[i] + \text{DeltaPocMsbCycleLt}[i - 1] \end{aligned} \quad (7-52)$$

`slice_temporal_mvp_enabled_flag` specifies whether temporal motion vector predictors can be used for inter prediction. If `slice_temporal_mvp_enabled_flag` is equal to 0, the syntax elements of the current picture shall be constrained such that no temporal motion vector predictor is used in decoding of the current picture. Otherwise (`slice_temporal_mvp_enabled_flag` is equal to 1), temporal motion vector predictors may be used in decoding of the current picture. When not present, the value of `slice_temporal_mvp_enabled_flag` is inferred to be equal to 0.

Let `currLayerId` be equal to `nuh_layer_id` of the current NAL unit. When both `slice_temporal_mvp_enabled_flag` and `TemporalId` are equal to 0, the syntax elements for all coded pictures with `nuh_layer_id` equal to `currLayerId` that follow the current picture in decoding order shall be constrained such that no temporal motion vector from any picture with `nuh_layer_id` equal to `currLayerId` that precedes the current picture in decoding order is used in decoding of any coded picture that follows the current picture in decoding order.

NOTE 3 – When `slice_temporal_mvp_enabled_flag` is equal to 0 in an I slice, it has no impact on the normative decoding process of the picture but merely expresses a bitstream constraint.

NOTE 4 – When `slice_temporal_mvp_enabled_flag` is equal to 0 in a slice with `TemporalId` equal to 0, decoders may empty "motion vector storage" for all reference pictures with `nuh_layer_id` equal to `currLayerId` in the decoded picture buffer.

slice_sao_luma_flag equal to 1 specifies that SAO is enabled for the luma component in the current slice; slice_sao_luma_flag equal to 0 specifies that SAO is disabled for the luma component in the current slice. When slice_sao_luma_flag is not present, it is inferred to be equal to 0.

slice_sao_chroma_flag equal to 1 specifies that SAO is enabled for the chroma component in the current slice; slice_sao_chroma_flag equal to 0 specifies that SAO is disabled for the chroma component in the current slice. When slice_sao_chroma_flag is not present, it is inferred to be equal to 0.

num_ref_idx_active_override_flag equal to 1 specifies that the syntax element num_ref_idx_l0_active_minus1 is present for P and B slices and that the syntax element num_ref_idx_l1_active_minus1 is present for B slices. num_ref_idx_active_override_flag equal to 0 specifies that the syntax elements num_ref_idx_l0_active_minus1 and num_ref_idx_l1_active_minus1 are not present.

num_ref_idx_l0_active_minus1 specifies the maximum reference index for reference picture list 0 that may be used to decode the slice. num_ref_idx_l0_active_minus1 shall be in the range of 0 to 14, inclusive. When the current slice is a P or B slice and num_ref_idx_l0_active_minus1 is not present, num_ref_idx_l0_active_minus1 is inferred to be equal to num_ref_idx_l0_default_active_minus1.

num_ref_idx_l1_active_minus1 specifies the maximum reference index for reference picture list 1 that may be used to decode the slice. num_ref_idx_l1_active_minus1 shall be in the range of 0 to 14, inclusive. When num_ref_idx_l1_active_minus1 is not present, num_ref_idx_l1_active_minus1 is inferred to be equal to num_ref_idx_l1_default_active_minus1.

mvd_l1_zero_flag equal to 1 indicates that the mvd_coding(x0, y0, 1) syntax structure is not parsed and MvdL1[x0][y0][compIdx] is set equal to 0 for compIdx = 0..1. mvd_l1_zero_flag equal to 0 indicates that the mvd_coding(x0, y0, 1) syntax structure is parsed.

cabac_init_flag specifies the method for determining the initialization table used in the initialization process for context variables. When cabac_init_flag is not present, it is inferred to be equal to 0.

collocated_from_l0_flag equal to 1 specifies that the collocated picture used for temporal motion vector prediction is derived from reference picture list 0. collocated_from_l0_flag equal to 0 specifies that the collocated picture used for temporal motion vector prediction is derived from reference picture list 1. When collocated_from_l0_flag is not present, it is inferred to be equal to 1.

collocated_ref_idx specifies the reference index of the collocated picture used for temporal motion vector prediction.

When slice_type is equal to P or when slice_type is equal to B and collocated_from_l0_flag is equal to 1, collocated_ref_idx refers to a picture in list 0, and the value of collocated_ref_idx shall be in the range of 0 to num_ref_idx_l0_active_minus1, inclusive.

When slice_type is equal to B and collocated_from_l0_flag is equal to 0, collocated_ref_idx refers to a picture in list 1 and the value of collocated_ref_idx shall be in the range of 0 to num_ref_idx_l1_active_minus1, inclusive.

When not present, the value of collocated_ref_idx is inferred to be equal to 0.

When slice_temporal_mvp_enabled_flag is equal to 1, it is a requirement of bitstream conformance that, for all slices of the current picture that have slice_type not equal to 2 (if any), the picture referred to by collocated_ref_idx shall be the same and shall not be the current picture.

NOTE 5 – This implies that when pps_curr_pic_ref_enabled_flag is equal to 1 and the current picture is the only reference picture in the reference picture list, slice_temporal_mvp_enabled_flag would be constrained to be equal to 0.

five_minus_max_num_merge_cand specifies the maximum number of merging motion vector prediction (MVP) candidates supported in the slice subtracted from 5. The maximum number of merging MVP candidates, MaxNumMergeCand is derived as follows:

$$\text{MaxNumMergeCand} = 5 - \text{five_minus_max_num_merge_cand} \quad (7-53)$$

The value of MaxNumMergeCand shall be in the range of 1 to 5, inclusive.

use_integer_mv_flag equal to 1 specifies that the resolution of motion vectors for inter prediction in the current slice is integer. use_integer_mv_flag equal to 0 specifies that the resolution of motion vectors for inter prediction in the current slice that refer to pictures other than the current picture is fractional with quarter-sample precision in units of luma samples. When not present, the value of use_integer_mv_flag is inferred to be equal to motion_vector_resolution_control_idc.

slice_qp_delta specifies the initial value of Qp_Y to be used for the coding blocks in the slice until modified by the value of CuQpDeltaVal in the coding unit layer. The initial value of the Qp_Y quantization parameter for the slice, SliceQp_Y, is derived as follows:

$$\text{SliceQp}_Y = 26 + \text{init_qp_minus26} + \text{slice_qp_delta} \quad (7-54)$$

The value of SliceQp_Y shall be in the range of $-\text{QpBdOffset}_Y$ to +51, inclusive.

slice_cb_qp_offset specifies a difference to be added to the value of pps_cb_qp_offset when determining the value of the Qp'_{Cb} quantization parameter. The value of $\text{slice_cb_qp_offset}$ shall be in the range of -12 to $+12$, inclusive. When $\text{slice_cb_qp_offset}$ is not present, it is inferred to be equal to 0. The value of $\text{pps_cb_qp_offset} + \text{slice_cb_qp_offset}$ shall be in the range of -12 to $+12$, inclusive.

slice_cr_qp_offset specifies a difference to be added to the value of pps_cr_qp_offset when determining the value of the Qp'_{Cr} quantization parameter. The value of $\text{slice_cr_qp_offset}$ shall be in the range of -12 to $+12$, inclusive. When $\text{slice_cr_qp_offset}$ is not present, it is inferred to be equal to 0. The value of $\text{pps_cr_qp_offset} + \text{slice_cr_qp_offset}$ shall be in the range of -12 to $+12$, inclusive.

slice_act_y_qp_offset, **slice_act_cb_qp_offset** and **slice_act_cr_qp_offset** specify offsets to the quantization parameter values qP derived in clause 8.6.2 for luma, Cb, and Cr components, respectively. The values of $\text{slice_act_y_qp_offset}$, $\text{slice_act_cb_qp_offset}$ and $\text{slice_act_cr_qp_offset}$ shall be in the range of -12 to $+12$, inclusive. When not present, the values of $\text{slice_act_y_qp_offset}$, $\text{slice_act_cb_qp_offset}$, and $\text{slice_act_cr_qp_offset}$ are inferred to be equal to 0. The value of $\text{PpsActQpOffsetY} + \text{slice_act_y_qp_offset}$ shall be in the range of -12 to $+12$, inclusive. The value of $\text{PpsActQpOffsetCb} + \text{slice_act_cb_qp_offset}$ shall be in the range of -12 to $+12$, inclusive. The value of $\text{PpsActQpOffsetCr} + \text{slice_act_cr_qp_offset}$ shall be in the range of -12 to $+12$, inclusive.

cu_chroma_qp_offset_enabled_flag equal to 1 specifies that the $\text{cu_chroma_qp_offset_flag}$ may be present in the transform unit syntax. $\text{cu_chroma_qp_offset_enabled_flag}$ equal to 0 specifies that the $\text{cu_chroma_qp_offset_flag}$ is not present in the transform unit syntax. When not present, the value of $\text{cu_chroma_qp_offset_enabled_flag}$ is inferred to be equal to 0.

deblocking_filter_override_flag equal to 1 specifies that deblocking parameters are present in the slice header. $\text{deblocking_filter_override_flag}$ equal to 0 specifies that deblocking parameters are not present in the slice header. When not present, the value of $\text{deblocking_filter_override_flag}$ is inferred to be equal to 0.

slice_deblocking_filter_disabled_flag equal to 1 specifies that the operation of the deblocking filter is not applied for the current slice. $\text{slice_deblocking_filter_disabled_flag}$ equal to 0 specifies that the operation of the deblocking filter is applied for the current slice. When $\text{slice_deblocking_filter_disabled_flag}$ is not present, it is inferred to be equal to $\text{pps_deblocking_filter_disabled_flag}$.

slice_beta_offset_div2 and **slice_tc_offset_div2** specify the deblocking parameter offsets for β and tC (divided by 2) for the current slice. The values of $\text{slice_beta_offset_div2}$ and $\text{slice_tc_offset_div2}$ shall both be in the range of -6 to 6 , inclusive. When not present, the values of $\text{slice_beta_offset_div2}$ and $\text{slice_tc_offset_div2}$ are inferred to be equal to $\text{pps_beta_offset_div2}$ and $\text{pps_tc_offset_div2}$, respectively.

slice_loop_filter_across_slices_enabled_flag equal to 1 specifies that in-loop filtering operations may be performed across the left and upper boundaries of the current slice. $\text{slice_loop_filter_across_slices_enabled_flag}$ equal to 0 specifies that in-loop operations are not performed across left and upper boundaries of the current slice. The in-loop filtering operations include the deblocking filter and sample adaptive offset filter. When $\text{slice_loop_filter_across_slices_enabled_flag}$ is not present, it is inferred to be equal to $\text{pps_loop_filter_across_slices_enabled_flag}$.

num_entry_point_offsets specifies the number of $\text{entry_point_offset_minus1}[i]$ syntax elements in the slice header. When not present, the value of $\text{num_entry_point_offsets}$ is inferred to be equal to 0.

The value of $\text{num_entry_point_offsets}$ is constrained as follows:

- If $\text{tiles_enabled_flag}$ is equal to 0 and $\text{entropy_coding_sync_enabled_flag}$ is equal to 1, the value of $\text{num_entry_point_offsets}$ shall be in the range of 0 to $\text{PicHeightInCtbsY} - 1$, inclusive.
- Otherwise, if $\text{tiles_enabled_flag}$ is equal to 1 and $\text{entropy_coding_sync_enabled_flag}$ is equal to 0, the value of $\text{num_entry_point_offsets}$ shall be in the range of 0 to $(\text{num_tile_columns_minus1} + 1) * (\text{num_tile_rows_minus1} + 1) - 1$, inclusive.
- Otherwise, when $\text{tiles_enabled_flag}$ is equal to 1 and $\text{entropy_coding_sync_enabled_flag}$ is equal to 1, the value of $\text{num_entry_point_offsets}$ shall be in the range of 0 to $(\text{num_tile_columns_minus1} + 1) * \text{PicHeightInCtbsY} - 1$, inclusive.

offset_len_minus1 plus 1 specifies the length, in bits, of the $\text{entry_point_offset_minus1}[i]$ syntax elements. The value of offset_len_minus1 shall be in the range of 0 to 31, inclusive.

entry_point_offset_minus1[i] plus 1 specifies the i -th entry point offset in bytes, and is represented by $\text{offset_len_minus1} + 1$ bits. The slice segment data that follow the slice segment header consists of $\text{num_entry_point_offsets} + 1$ subsets, with subset index values ranging from 0 to $\text{num_entry_point_offsets}$, inclusive. The

first byte of the slice segment data is considered byte 0. When present, emulation prevention bytes that appear in the slice segment data portion of the coded slice segment NAL unit are counted as part of the slice segment data for purposes of subset identification. Subset 0 consists of bytes 0 to `entry_point_offset_minus1[0]`, inclusive, of the coded slice segment data, subset `k`, with `k` in the range of 1 to `num_entry_point_offsets - 1`, inclusive, consists of bytes `firstByte[k]` to `lastByte[k]`, inclusive, of the coded slice segment data with `firstByte[k]` and `lastByte[k]` defined as:

$$\text{firstByte}[k] = \sum_{n=1}^k (\text{entry_point_offset_minus1}[n-1] + 1) \quad (7-55)$$

$$\text{lastByte}[k] = \text{firstByte}[k] + \text{entry_point_offset_minus1}[k] \quad (7-56)$$

The last subset (with subset index equal to `num_entry_point_offsets`) consists of the remaining bytes of the coded slice segment data.

When `tiles_enabled_flag` is equal to 1 and `entropy_coding_sync_enabled_flag` is equal to 0, each subset shall consist of all coded bits of all CTUs in the slice segment that are within the same tile, and the number of subsets (i.e., the value of `num_entry_point_offsets + 1`) shall be equal to the number of tiles that contain CTUs that are in the coded slice segment.

NOTE 6 – When `tiles_enabled_flag` is equal to 1 and `entropy_coding_sync_enabled_flag` is equal to 0, each slice must include either a subset of the CTUs of one tile (in which case the syntax element `entry_point_offset_minus1[i]` is not present) or must include all CTUs of an integer number of complete tiles.

When `tiles_enabled_flag` is equal to 0 and `entropy_coding_sync_enabled_flag` is equal to 1, each subset `k` with `k` in the range of 0 to `num_entry_point_offsets`, inclusive, shall consist of all coded bits of all CTUs in the slice segment that include luma CTBs that are in the same luma CTB row of the picture, and the number of subsets (i.e., the value of `num_entry_point_offsets + 1`) shall be equal to the number of CTB rows of the picture that contain CTUs that are in the coded slice segment.

NOTE 7 – The last subset (i.e., subset `k` for `k` equal to `num_entry_point_offsets`) may or may not contain all CTUs that include luma CTBs that are in a luma CTB row of the picture.

When `tiles_enabled_flag` is equal to 1 and `entropy_coding_sync_enabled_flag` is equal to 1, each subset `k` with `k` in the range of 0 to `num_entry_point_offsets`, inclusive, shall consist of all coded bits of all CTUs in the slice segment that include luma CTBs that are in the same luma CTB row within a tile, and the number of subsets (i.e., the value of `num_entry_point_offsets + 1`) shall be equal to the number of luma CTB row scans in the tile scan for the CTUs of the coded slice segment.

slice_segment_header_extension_length specifies the length of the slice segment header extension data in bytes, not including the bits used for signalling **slice_segment_header_extension_length** itself. The value of **slice_segment_header_extension_length** shall be in the range of 0 to 256, inclusive. When not present, the value of **slice_segment_header_extension_length** is inferred to be equal to 0.

slice_segment_header_extension_data_byte may have any value. Decoders shall ignore the value of **slice_segment_header_extension_data_byte**. Its value does not affect the decoding process of the profiles specified in Annex A.

7.4.7.2 Reference picture list modification semantics

ref_pic_list_modification_flag_l0 equal to 1 indicates that reference picture list 0 is specified explicitly by a list of `list_entry_l0[i]` values. **ref_pic_list_modification_flag_l0** equal to 0 indicates that reference picture list 0 is determined implicitly. When **ref_pic_list_modification_flag_l0** is not present in the slice header, it is inferred to be equal to 0.

list_entry_l0[i] specifies the index of the reference picture in `RefPicListTemp0` to be placed at the current position of reference picture list 0. The length of the `list_entry_l0[i]` syntax element is $\text{Ceil}(\text{Log2}(\text{NumPicTotalCurr}))$ bits. The value of `list_entry_l0[i]` shall be in the range of 0 to `NumPicTotalCurr - 1`, inclusive. When the syntax element `list_entry_l0[i]` is not present in the slice header, it is inferred to be equal to 0.

The variable `NumPicTotalCurr` is derived as follows:

```

NumPicTotalCurr = 0
for( i = 0; i < NumNegativePics[ CurrRpsIdx ]; i++ )
    if( UsedByCurrPicS0[ CurrRpsIdx ][ i ] )
        NumPicTotalCurr++
for( i = 0; i < NumPositivePics[ CurrRpsIdx ]; i++ )
    if( UsedByCurrPicS1[ CurrRpsIdx ][ i ] )
        NumPicTotalCurr++
for( i = 0; i < num_long_term_sps + num_long_term_pics; i++ )

```

(7-57)

```

        if( UsedByCurrPicLt[ i ] )
            NumPicTotalCurr++
    if( pps_curr_pic_ref_enabled_flag )
        NumPicTotalCurr++

```

ref_pic_list_modification_flag_11 equal to 1 indicates that reference picture list 1 is specified explicitly by a list of **list_entry_11[i]** values. **ref_pic_list_modification_flag_11** equal to 0 indicates that reference picture list 1 is determined implicitly. When **ref_pic_list_modification_flag_11** is not present in the slice header, it is inferred to be equal to 0.

list_entry_11[i] specifies the index of the reference picture in **RefPicListTemp1** to be placed at the current position of reference picture list 1. The length of the **list_entry_11[i]** syntax element is $\text{Ceil}(\text{Log2}(\text{NumPicTotalCurr}))$ bits. The value of **list_entry_11[i]** shall be in the range of 0 to **NumPicTotalCurr** – 1, inclusive. When the syntax element **list_entry_11[i]** is not present in the slice header, it is inferred to be equal to 0.

7.4.7.3 Weighted prediction parameters semantics

luma_log2_weight_denom is the base 2 logarithm of the denominator for all luma weighting factors. The value of **luma_log2_weight_denom** shall be in the range of 0 to 7, inclusive.

delta_chroma_log2_weight_denom is the difference of the base 2 logarithm of the denominator for all chroma weighting factors. When **delta_chroma_log2_weight_denom** is not present, it is inferred to be equal to 0.

The variable **ChromaLog2WeightDenom** is derived to be equal to **luma_log2_weight_denom** + **delta_chroma_log2_weight_denom** and the value shall be in the range of 0 to 7, inclusive.

luma_weight_10_flag[i] equal to 1 specifies that weighting factors for the luma component of list 0 prediction using **RefPicList0[i]** are present. **luma_weight_10_flag[i]** equal to 0 specifies that these weighting factors are not present. When **luma_weight_10_flag[i]** is not present, it is inferred to be equal to 0.

chroma_weight_10_flag[i] equal to 1 specifies that weighting factors for the chroma prediction values of list 0 prediction using **RefPicList0[i]** are present. **chroma_weight_10_flag[i]** equal to 0 specifies that these weighting factors are not present. When **chroma_weight_10_flag[i]** is not present, it is inferred to be equal to 0.

delta_luma_weight_10[i] is the difference of the weighting factor applied to the luma prediction value for list 0 prediction using **RefPicList0[i]**.

The variable **LumaWeightL0[i]** is derived to be equal to $(1 \ll \text{luma_log2_weight_denom}) + \text{delta_luma_weight_10}[i]$. When **luma_weight_10_flag[i]** is equal to 1, the value of **delta_luma_weight_10[i]** shall be in the range of –128 to 127, inclusive. When **luma_weight_10_flag[i]** is equal to 0, **LumaWeightL0[i]** is inferred to be equal to $2^{\text{luma_log2_weight_denom}}$.

luma_offset_10[i] is the additive offset applied to the luma prediction value for list 0 prediction using **RefPicList0[i]**. The value of **luma_offset_10[i]** shall be in the range of $-\text{WpOffsetHalfRange}_Y$ to $\text{WpOffsetHalfRange}_Y - 1$, inclusive. When **luma_weight_10_flag[i]** is equal to 0, **luma_offset_10[i]** is inferred to be equal to 0.

delta_chroma_weight_10[i][j] is the difference of the weighting factor applied to the chroma prediction values for list 0 prediction using **RefPicList0[i]** with **j** equal to 0 for Cb and **j** equal to 1 for Cr.

The variable **ChromaWeightL0[i][j]** is derived to be equal to $(1 \ll \text{ChromaLog2WeightDenom}) + \text{delta_chroma_weight_10}[i][j]$. When **chroma_weight_10_flag[i]** is equal to 1, the value of **delta_chroma_weight_10[i][j]** shall be in the range of –128 to 127, inclusive. When **chroma_weight_10_flag[i]** is equal to 0, **ChromaWeightL0[i][j]** is inferred to be equal to $2^{\text{ChromaLog2WeightDenom}}$.

delta_chroma_offset_10[i][j] is the difference of the additive offset applied to the chroma prediction values for list 0 prediction using **RefPicList0[i]** with **j** equal to 0 for Cb and **j** equal to 1 for Cr.

The variable **ChromaOffsetL0[i][j]** is derived as follows:

$$\begin{aligned} \text{ChromaOffsetL0}[i][j] = & \text{Clip3}(-\text{WpOffsetHalfRange}_C, \text{WpOffsetHalfRange}_C - 1, \\ & (\text{WpOffsetHalfRange}_C + \text{delta_chroma_offset_10}[i][j] - \\ & ((\text{WpOffsetHalfRange}_C * \text{ChromaWeightL0}[i][j]) \gg \text{ChromaLog2WeightDenom}))) \end{aligned} \quad (7-58)$$

The value of **delta_chroma_offset_10[i][j]** shall be in the range of $-4 * \text{WpOffsetHalfRange}_C$ to $4 * \text{WpOffsetHalfRange}_C - 1$, inclusive. When **chroma_weight_10_flag[i]** is equal to 0, **ChromaOffsetL0[i][j]** is inferred to be equal to 0.

luma_weight_11_flag[i], **chroma_weight_11_flag[i]**, **delta_luma_weight_11[i]**, **luma_offset_11[i]**, **delta_chroma_weight_11[i][j]** and **delta_chroma_offset_11[i][j]** have the same semantics as **luma_weight_10_flag[i]**, **chroma_weight_10_flag[i]**, **delta_luma_weight_10[i]**, **luma_offset_10[i]**,

$\text{delta_chroma_weight_l0}[i][j]$ and $\text{delta_chroma_offset_l0}[i][j]$, respectively, with l0, L0, list 0 and List0 replaced by l1, L1, list 1 and List1, respectively.

The variable sumWeightL0Flags is derived to be equal to the sum of $\text{luma_weight_l0_flag}[i] + 2 * \text{chroma_weight_l0_flag}[i]$, for $i = 0.. \text{num_ref_idx_l0_active_minus1}$.

When slice_type is equal to B, the variable sumWeightL1Flags is derived to be equal to the sum of $\text{luma_weight_l1_flag}[i] + 2 * \text{chroma_weight_l1_flag}[i]$, for $i = 0.. \text{num_ref_idx_l1_active_minus1}$.

It is a requirement of bitstream conformance that, when slice_type is equal to P, sumWeightL0Flags shall be less than or equal to 24 and when slice_type is equal to B, the sum of sumWeightL0Flags and sumWeightL1Flags shall be less than or equal to 24.

7.4.8 Short-term reference picture set semantics

The $\text{st_ref_pic_set}(\text{stRpsIdx})$ syntax structure may be present in an SPS or in a slice header. Depending on whether the syntax structure is included in a slice header or an SPS, the following applies:

- If present in a slice header, the $\text{st_ref_pic_set}(\text{stRpsIdx})$ syntax structure specifies the short-term RPS of the current picture (the picture containing the slice), and the following applies:
 - The content of the $\text{st_ref_pic_set}(\text{stRpsIdx})$ syntax structure shall be the same in all slice headers of the current picture.
 - The value of stRpsIdx shall be equal to the syntax element $\text{num_short_term_ref_pic_sets}$ in the active SPS.
 - The short-term RPS of the current picture is also referred to as the $\text{num_short_term_ref_pic_sets}$ -th candidate short-term RPS in the semantics specified in the remainder of this clause.
- Otherwise (present in an SPS), the $\text{st_ref_pic_set}(\text{stRpsIdx})$ syntax structure specifies a candidate short-term RPS, and the term "the current picture" in the semantics specified in the remainder of this clause refers to each picture that has $\text{short_term_ref_pic_set_idx}$ equal to stRpsIdx in a CVS that has the SPS as the active SPS.

$\text{inter_ref_pic_set_prediction_flag}$ equal to 1 specifies that the stRpsIdx -th candidate short-term RPS is predicted from another candidate short-term RPS, which is referred to as the source candidate short-term RPS. When $\text{inter_ref_pic_set_prediction_flag}$ is not present, it is inferred to be equal to 0.

delta_idx_minus1 plus 1 specifies the difference between the value of stRpsIdx and the index, into the list of the candidate short-term RPSs specified in the SPS, of the source candidate short-term RPS. The value of delta_idx_minus1 shall be in the range of 0 to $\text{stRpsIdx} - 1$, inclusive. When delta_idx_minus1 is not present, it is inferred to be equal to 0.

The variable RefRpsIdx is derived as follows:

$$\text{RefRpsIdx} = \text{stRpsIdx} - (\text{delta_idx_minus1} + 1) \quad (7-59)$$

delta_rps_sign and $\text{abs_delta_rps_minus1}$ together specify the value of the variable deltaRps as follows:

$$\text{deltaRps} = (1 - 2 * \text{delta_rps_sign}) * (\text{abs_delta_rps_minus1} + 1) \quad (7-60)$$

The variable deltaRps represents the value to be added to the picture order count difference values of the source candidate short-term RPS to obtain the picture order count difference values of the stRpsIdx -th candidate short-term RPS. The value of $\text{abs_delta_rps_minus1}$ shall be in the range of 0 to $2^{15} - 1$, inclusive.

$\text{used_by_curr_pic_flag}[j]$ equal to 0 specifies that the j -th entry in the source candidate short-term RPS is not used for reference by the current picture.

$\text{use_delta_flag}[j]$ equal to 1 specifies that the j -th entry in the source candidate short-term RPS is included in the stRpsIdx -th candidate short-term RPS. $\text{use_delta_flag}[j]$ equal to 0 specifies that the j -th entry in the source candidate short-term RPS is not included in the stRpsIdx -th candidate short-term RPS. When $\text{use_delta_flag}[j]$ is not present, its value is inferred to be equal to 1.

When $\text{inter_ref_pic_set_prediction_flag}$ is equal to 1, the variables $\text{DeltaPocS0}[\text{stRpsIdx}][i]$, $\text{UsedByCurrPicS0}[\text{stRpsIdx}][i]$, $\text{NumNegativePics}[\text{stRpsIdx}]$, $\text{DeltaPocS1}[\text{stRpsIdx}][i]$, $\text{UsedByCurrPicS1}[\text{stRpsIdx}][i]$ and $\text{NumPositivePics}[\text{stRpsIdx}]$ are derived as follows:

```
i = 0
for( j = NumPositivePics[ RefRpsIdx ] - 1; j >= 0; j-- ) {
    dPoc = DeltaPocS1[ RefRpsIdx ][ j ] + deltaRps
```

```

        if( dPoc < 0 && use_delta_flag[ NumNegativePics[ RefRpsIdx ] + j ] ) {
            DeltaPocS0[ stRpsIdx ][ i ] = dPoc
            UsedByCurrPicS0[ stRpsIdx ][ i++ ] =
used_by_curr_pic_flag[ NumNegativePics[ RefRpsIdx ] + j ]
        }
    }
    if( deltaRps < 0 && use_delta_flag[ NumDeltaPocs[ RefRpsIdx ] ] ) {
        DeltaPocS0[ stRpsIdx ][ i ] = deltaRps
        UsedByCurrPicS0[ stRpsIdx ][ i++ ] = used_by_curr_pic_flag[ NumDeltaPocs[ RefRpsIdx ] ]
    }
    for( j = 0; j < NumNegativePics[ RefRpsIdx ]; j++ ) {
        dPoc = DeltaPocS0[ RefRpsIdx ][ j ] + deltaRps
        if( dPoc < 0 && use_delta_flag[ j ] ) {
            DeltaPocS0[ stRpsIdx ][ i ] = dPoc
            UsedByCurrPicS0[ stRpsIdx ][ i++ ] = used_by_curr_pic_flag[ j ]
        }
    }
    NumNegativePics[ stRpsIdx ] = i

    i = 0
    for( j = NumNegativePics[ RefRpsIdx ] - 1; j >= 0; j-- ) {
        dPoc = DeltaPocS0[ RefRpsIdx ][ j ] + deltaRps
        if( dPoc > 0 && use_delta_flag[ j ] ) {
            DeltaPocS1[ stRpsIdx ][ i ] = dPoc
            UsedByCurrPicS1[ stRpsIdx ][ i++ ] = used_by_curr_pic_flag[ j ]
        }
    }
    if( deltaRps > 0 && use_delta_flag[ NumDeltaPocs[ RefRpsIdx ] ] ) {
        DeltaPocS1[ stRpsIdx ][ i ] = deltaRps
        UsedByCurrPicS1[ stRpsIdx ][ i++ ] = used_by_curr_pic_flag[ NumDeltaPocs[ RefRpsIdx ] ]
    }
    for( j = 0; j < NumPositivePics[ RefRpsIdx ]; j++ ) {
        dPoc = DeltaPocS1[ RefRpsIdx ][ j ] + deltaRps
        if( dPoc > 0 && use_delta_flag[ NumNegativePics[ RefRpsIdx ] + j ] ) {
            DeltaPocS1[ stRpsIdx ][ i ] = dPoc
            UsedByCurrPicS1[ stRpsIdx ][ i++ ] =
used_by_curr_pic_flag[ NumNegativePics[ RefRpsIdx ] + j ]
        }
    }
    NumPositivePics[ stRpsIdx ] = i

```

num_negative_pics specifies the number of entries in the stRpsIdx-th candidate short-term RPS that have picture order count values less than the picture order count value of the current picture. When nuh_layer_id of the current picture is equal to 0, the value of num_negative_pics shall be in the range of 0 to sps_max_dec_pic_buffering_minus1[sps_max_sub_layers_minus1], inclusive.

num_positive_pics specifies the number of entries in the stRpsIdx-th candidate short-term RPS that have picture order count values greater than the picture order count value of the current picture. When nuh_layer_id of the current picture is equal to 0, the value of num_positive_pics shall be in the range of 0 to sps_max_dec_pic_buffering_minus1[sps_max_sub_layers_minus1] - num_negative_pics, inclusive.

delta_poc_s0_minus1[i] plus 1, when i is equal to 0, specifies the difference between the picture order count values of the current picture and the i-th entry in the stRpsIdx-th candidate short-term RPS that has picture order count value less than that of the current picture, or, when i is greater than 0, specifies the difference between the picture order count values of the (i - 1)-th entry and the i-th entry in the stRpsIdx-th candidate short-term RPS that have picture order count values less than the picture order count value of the current picture. The value of delta_poc_s0_minus1[i] shall be in the range of 0 to $2^{15} - 1$, inclusive.

used_by_curr_pic_s0_flag[i] equal to 0 specifies that the i-th entry in the stRpsIdx-th candidate short-term RPS that has picture order count value less than that of the current picture is not used for reference by the current picture.

delta_poc_s1_minus1[i] plus 1, when i is equal to 0, specifies the difference between the picture order count values of the current picture and the i-th entry in the stRpsIdx-th candidate short-term RPS that has picture order count value greater than that of the current picture, or, when i is greater than 0, specifies the difference between the picture order count values of the i-th entry and the (i – 1)-th entry in the current candidate short-term RPS that have picture order count values greater than the picture order count value of the current picture. The value of delta_poc_s1_minus1[i] shall be in the range of 0 to $2^{15} - 1$, inclusive.

used_by_curr_pic_s1_flag[i] equal to 0 specifies that the i-th entry in the current candidate short-term RPS that has picture order count value greater than that of the current picture is not used for reference by the current picture.

When **inter_ref_pic_set_prediction_flag** is equal to 0, the variables **NumNegativePics**[stRpsIdx], **NumPositivePics**[stRpsIdx], **UsedByCurrPicS0**[stRpsIdx][i], **UsedByCurrPicS1**[stRpsIdx][i], **DeltaPocS0**[stRpsIdx][i] and **DeltaPocS1**[stRpsIdx][i] are derived as follows:

$$\text{NumNegativePics}[\text{stRpsIdx}] = \text{num_negative_pics} \quad (7-63)$$

$$\text{NumPositivePics}[\text{stRpsIdx}] = \text{num_positive_pics} \quad (7-64)$$

$$\text{UsedByCurrPicS0}[\text{stRpsIdx}][i] = \text{used_by_curr_pic_s0_flag}[i] \quad (7-65)$$

$$\text{UsedByCurrPicS1}[\text{stRpsIdx}][i] = \text{used_by_curr_pic_s1_flag}[i] \quad (7-66)$$

– If i is equal to 0, the following applies:

$$\text{DeltaPocS0}[\text{stRpsIdx}][i] = -(\text{delta_poc_s0_minus1}[i] + 1) \quad (7-67)$$

$$\text{DeltaPocS1}[\text{stRpsIdx}][i] = \text{delta_poc_s1_minus1}[i] + 1 \quad (7-68)$$

– Otherwise, the following applies:

$$\text{DeltaPocS0}[\text{stRpsIdx}][i] = \text{DeltaPocS0}[\text{stRpsIdx}][i - 1] - (\text{delta_poc_s0_minus1}[i] + 1) \quad (7-69)$$

$$\text{DeltaPocS1}[\text{stRpsIdx}][i] = \text{DeltaPocS1}[\text{stRpsIdx}][i - 1] + (\text{delta_poc_s1_minus1}[i] + 1) \quad (7-70)$$

The variable **NumDeltaPocs**[stRpsIdx] is derived as follows:

$$\text{NumDeltaPocs}[\text{stRpsIdx}] = \text{NumNegativePics}[\text{stRpsIdx}] + \text{NumPositivePics}[\text{stRpsIdx}] \quad (7-71)$$

7.4.9 Slice segment data semantics

7.4.9.1 General slice segment data semantics

end_of_slice_segment_flag equal to 0 specifies that another CTU is following in the slice. **end_of_slice_segment_flag** equal to 1 specifies the end of the slice segment, i.e., that no further CTU follows in the slice segment.

end_of_subset_one_bit shall be equal to 1.

7.4.9.2 Coding tree unit semantics

The CTU is the root node of the coding quadtree structure.

7.4.9.3 Sample adaptive offset semantics

sao_merge_left_flag equal to 1 specifies that the syntax elements **sao_type_idx_luma**, **sao_type_idx_chroma**, **sao_band_position**, **sao_eo_class_luma**, **sao_eo_class_chroma**, **sao_offset_abs** and **sao_offset_sign** are derived from the corresponding syntax elements of the left CTB. **sao_merge_left_flag** equal to 0 specifies that these syntax elements are not derived from the corresponding syntax elements of the left CTB. When **sao_merge_left_flag** is not present, it is inferred to be equal to 0.

sao_merge_up_flag equal to 1 specifies that the syntax elements **sao_type_idx_luma**, **sao_type_idx_chroma**, **sao_band_position**, **sao_eo_class_luma**, **sao_eo_class_chroma**, **sao_offset_abs** and **sao_offset_sign** are derived from the corresponding syntax elements of the above CTB. **sao_merge_up_flag** equal to 0 specifies that these syntax elements are

not derived from the corresponding syntax elements of the above CTB. When `sao_merge_up_flag` is not present, it is inferred to be equal to 0.

sao_type_idx_luma specifies the offset type for the luma component. The array `SaoTypeIdx[cIdx][rx][ry]` specifies the offset type as specified in Table 7-8 for the CTB at the location (rx, ry) for the colour component cIdx. The value of `SaoTypeIdx[0][rx][ry]` is derived as follows:

- If `sao_type_idx_luma` is present, `SaoTypeIdx[0][rx][ry]` is set equal to `sao_type_idx_luma`.
- Otherwise (`sao_type_idx_luma` is not present), `SaoTypeIdx[0][rx][ry]` is derived as follows:
 - If `sao_merge_left_flag` is equal to 1, `SaoTypeIdx[0][rx][ry]` is set equal to `SaoTypeIdx[0][rx - 1][ry]`.
 - Otherwise, if `sao_merge_up_flag` is equal to 1, `SaoTypeIdx[0][rx][ry]` is set equal to `SaoTypeIdx[0][rx][ry - 1]`.
 - Otherwise, `SaoTypeIdx[0][rx][ry]` is set equal to 0.

sao_type_idx_chroma specifies the offset type for the chroma components. The values of `SaoTypeIdx[cIdx][rx][ry]` are derived as follows for cIdx equal to 1..2:

- If `sao_type_idx_chroma` is present, `SaoTypeIdx[cIdx][rx][ry]` is set equal to `sao_type_idx_chroma`.
- Otherwise (`sao_type_idx_chroma` is not present), `SaoTypeIdx[cIdx][rx][ry]` is derived as follows:
 - If `sao_merge_left_flag` is equal to 1, `SaoTypeIdx[cIdx][rx][ry]` is set equal to `SaoTypeIdx[cIdx][rx - 1][ry]`.
 - Otherwise, if `sao_merge_up_flag` is equal to 1, `SaoTypeIdx[cIdx][rx][ry]` is set equal to `SaoTypeIdx[cIdx][rx][ry - 1]`.
 - Otherwise, `SaoTypeIdx[cIdx][rx][ry]` is set equal to 0.

Table 7-8 – Specification of the SAO type

SaoTypeIdx[cIdx][rx][ry]	SAO type (informative)
0	Not applied
1	Band offset
2	Edge offset

sao_offset_abs[cIdx][rx][ry][i] specifies the offset value of i-th category for the CTB at the location (rx, ry) for the colour component cIdx.

When `sao_offset_abs[cIdx][rx][ry][i]` is not present, it is inferred as follows:

- If `sao_merge_left_flag` is equal to 1, `sao_offset_abs[cIdx][rx][ry][i]` is inferred to be equal to `sao_offset_abs[cIdx][rx - 1][ry][i]`.
- Otherwise, if `sao_merge_up_flag` is equal to 1, `sao_offset_abs[cIdx][rx][ry][i]` is inferred to be equal to `sao_offset_abs[cIdx][rx][ry - 1][i]`.
- Otherwise, `sao_offset_abs[cIdx][rx][ry][i]` is inferred to be equal to 0.

sao_offset_sign[cIdx][rx][ry][i] specifies the sign of the offset value of i-th category for the CTB at the location (rx, ry) for the colour component cIdx.

When `sao_offset_sign[cIdx][rx][ry][i]` is not present, it is inferred as follows:

- If `sao_merge_left_flag` is equal to 1, `sao_offset_sign[cIdx][rx][ry][i]` is inferred to be equal to `sao_offset_sign[cIdx][rx - 1][ry][i]`.
- Otherwise, if `sao_merge_up_flag` is equal to 1, `sao_offset_sign[cIdx][rx][ry][i]` is inferred to be equal to `sao_offset_sign[cIdx][rx][ry - 1][i]`.
- Otherwise, if `SaoTypeIdx[cIdx][rx][ry]` is equal to 2, the following applies:
 - If i is equal to 0 or 1, `sao_offset_sign[cIdx][rx][ry][i]` is inferred to be equal 0.
 - Otherwise (i is equal to 2 or 3), `sao_offset_sign[cIdx][rx][ry][i]` is inferred to be equal 1.
- Otherwise, `sao_offset_sign[cIdx][rx][ry][i]` is inferred to be equal 0.

The variable log2OffsetScale is derived as follows:

- If cIdx is equal to 0, log2OffsetScale is set equal to log2_sao_offset_scale_luma.
- Otherwise (cIdx is equal to 1 or 2), log2OffsetScale is set equal to log2_sao_offset_scale_chroma.

The list SaoOffsetVal[cIdx][rx][ry][i] for i ranging from 0 to 4, inclusive, is derived as follows:

$$\begin{aligned} \text{SaoOffsetVal}[\text{cIdx}][\text{rx}][\text{ry}][0] &= 0 \\ \text{for}(i = 0; i < 4; i++) \\ \text{SaoOffsetVal}[\text{cIdx}][\text{rx}][\text{ry}][i + 1] &= (1 - 2 * \text{sao_offset_sign}[\text{cIdx}][\text{rx}][\text{ry}][i]) * \\ &\quad \text{sao_offset_abs}[\text{cIdx}][\text{rx}][\text{ry}][i] << \text{log2OffsetScale} \end{aligned} \quad (7-72)$$

sao_band_position[cIdx][rx][ry] specifies the displacement of the band offset of the sample range when SaoTypeIdx[cIdx][rx][ry] is equal to 1.

When sao_band_position[cIdx][rx][ry] is not present, it is inferred as follows:

- If sao_merge_left_flag is equal to 1, sao_band_position[cIdx][rx][ry] is inferred to be equal to sao_band_position[cIdx][rx - 1][ry].
- Otherwise, if sao_merge_up_flag is equal to 1, sao_band_position[cIdx][rx][ry] is inferred to be equal to sao_band_position[cIdx][rx][ry - 1].
- Otherwise, sao_band_position[cIdx][rx][ry] is inferred to be equal to 0.

sao_eo_class_luma specifies the edge offset class for the luma component. The array SaoEoClass[cIdx][rx][ry] specifies the offset type as specified in Table 7-9 for the CTB at the location (rx, ry) for the colour component cIdx. The value of SaoEoClass[0][rx][ry] is derived as follows:

- If sao_eo_class_luma is present, SaoEoClass[0][rx][ry] is set equal to sao_eo_class_luma.
- Otherwise (sao_eo_class_luma is not present), SaoEoClass[0][rx][ry] is derived as follows:
 - If sao_merge_left_flag is equal to 1, SaoEoClass[0][rx][ry] is set equal to SaoEoClass[0][rx - 1][ry].
 - Otherwise, if sao_merge_up_flag is equal to 1, SaoEoClass[0][rx][ry] is set equal to SaoEoClass[0][rx][ry - 1].
 - Otherwise, SaoEoClass[0][rx][ry] is set equal to 0.

sao_eo_class_chroma specifies the edge offset class for the chroma components. The values of SaoEoClass[cIdx][rx][ry] are derived as follows for cIdx equal to 1..2:

- If sao_eo_class_chroma is present, SaoEoClass[cIdx][rx][ry] is set equal to sao_eo_class_chroma.
- Otherwise (sao_eo_class_chroma is not present), SaoEoClass[cIdx][rx][ry] is derived as follows:
 - If sao_merge_left_flag is equal to 1, SaoEoClass[cIdx][rx][ry] is set equal to SaoEoClass[cIdx][rx - 1][ry].
 - Otherwise, if sao_merge_up_flag is equal to 1, SaoEoClass[cIdx][rx][ry] is set equal to SaoEoClass[cIdx][rx][ry - 1].
 - Otherwise, SaoEoClass[cIdx][rx][ry] is set equal to 0.

Table 7-9 – Specification of the SAO edge offset class

SaoEoClass[cIdx][rx][ry]	SAO edge offset class (informative)
0	1D 0-degree edge offset
1	1D 90-degree edge offset
2	1D 135-degree edge offset
3	1D 45-degree edge offset

7.4.9.4 Coding quadtree semantics

split_cu_flag[x0][y0] specifies whether a coding unit is split into coding units with half horizontal and vertical size. The array indices x0, y0 specify the location (x0, y0) of the top-left luma sample of the considered coding block relative to the top-left luma sample of the picture.

When **split_cu_flag**[x0][y0] is not present, the following applies:

- If $\log_2\text{CbSize}$ is greater than MinCbLog2SizeY , the value of **split_cu_flag**[x0][y0] is inferred to be equal to 1.
- Otherwise ($\log_2\text{CbSize}$ is equal to MinCbLog2SizeY), the value of **split_cu_flag**[x0][y0] is inferred to be equal to 0.

The array **CtDepth**[x][y] specifies the coding tree depth for a luma coding block covering the location (x, y). When **split_cu_flag**[x0][y0] is equal to 0, **CtDepth**[x][y] is inferred to be equal to **cqtDepth** for $x = x0..x0 + \text{nCbS} - 1$ and $y = y0..y0 + \text{nCbS} - 1$.

7.4.9.5 Coding unit semantics

cu_transquant_bypass_flag equal to 1 specifies that the scaling and transform process as specified in clause 8.6 and the in-loop filter process as specified in clause 8.7 are bypassed. When **cu_transquant_bypass_flag** is not present, it is inferred to be equal to 0.

cu_skip_flag[x0][y0] equal to 1 specifies that for the current coding unit, when decoding a P or B slice, no more syntax elements except the merging candidate index **merge_idx**[x0][y0] are parsed after **cu_skip_flag**[x0][y0]. **cu_skip_flag**[x0][y0] equal to 0 specifies that the coding unit is not skipped. The array indices x0, y0 specify the location (x0, y0) of the top-left luma sample of the considered coding block relative to the top-left luma sample of the picture.

When **cu_skip_flag**[x0][y0] is not present, it is inferred to be equal to 0.

pred_mode_flag equal to 0 specifies that the current coding unit is coded in inter prediction mode. **pred_mode_flag** equal to 1 specifies that the current coding unit is coded in intra prediction mode. The variable **CuPredMode**[x][y] is derived as follows for $x = x0..x0 + \text{nCbS} - 1$ and $y = y0..y0 + \text{nCbS} - 1$:

- If **pred_mode_flag** is equal to 0, **CuPredMode**[x][y] is set equal to **MODE_INTER**.
- Otherwise (**pred_mode_flag** is equal to 1), **CuPredMode**[x][y] is set equal to **MODE_INTRA**.

When **pred_mode_flag** is not present, the variable **CuPredMode**[x][y] is derived as follows for $x = x0..x0 + \text{nCbS} - 1$ and $y = y0..y0 + \text{nCbS} - 1$:

- If **slice_type** is equal to I, **CuPredMode**[x][y] is inferred to be equal to **MODE_INTRA**.
- Otherwise (**slice_type** is equal to P or B), when **cu_skip_flag**[x0][y0] is equal to 1, **CuPredMode**[x][y] is inferred to be equal to **MODE_SKIP**.

palette_mode_flag[x0][y0] equal to 1 specifies that the current coding unit is coded using the palette mode. **palette_mode_flag**[x0][y0] equal to 0 specifies that the current coding unit is not coded using the palette mode. The array indices x0 and y0 specify the location (x0, y0) of the top-left luma sample of the considered coding block relative to the top-left luma sample of the picture.

When **palette_mode_flag**[x0][y0] is not present, it is inferred to be equal to 0.

part_mode specifies the partitioning mode of the current coding unit. The semantics of **part_mode** depend on **CuPredMode**[x0][y0]. The variables **PartMode** and **IntraSplitFlag** are derived from the value of **part_mode** as defined in Table 7-10.

The value of **part_mode** is restricted as follows:

- If **CuPredMode**[x0][y0] is equal to **MODE_INTRA**, **part_mode** shall be equal to 0 or 1.
- Otherwise (**CuPredMode**[x0][y0] is equal to **MODE_INTER**), the following applies:
 - If $\log_2\text{CbSize}$ is greater than MinCbLog2SizeY and **amp_enabled_flag** is equal to 1, **part_mode** shall be in the range of 0 to 2, inclusive, or in the range of 4 to 7, inclusive.
 - Otherwise, if $\log_2\text{CbSize}$ is greater than MinCbLog2SizeY and **amp_enabled_flag** is equal to 0, or $\log_2\text{CbSize}$ is equal to 3, **part_mode** shall be in the range of 0 to 2, inclusive.
 - Otherwise ($\log_2\text{CbSize}$ is greater than 3 and equal to MinCbLog2SizeY), the value of **part_mode** shall be in the range of 0 to 3, inclusive.

When **part_mode** is not present, the variables **PartMode** and **IntraSplitFlag** are derived as follows:

- PartMode is set equal to PART_2Nx2N.
- IntraSplitFlag is set equal to 0.

pcm_flag[x0][y0] equal to 1 specifies that the pcm_sample() syntax structure is present and the transform_tree() syntax structure is not present in the coding unit including the luma coding block at the location (x0, y0). pcm_flag[x0][y0] equal to 0 specifies that pcm_sample() syntax structure is not present. When pcm_flag[x0][y0] is not present, it is inferred to be equal to 0.

The value of pcm_flag[x0 + i][y0 + j] with $i = 1..nC_{bS} - 1$, $j = 1..nC_{bS} - 1$ is inferred to be equal to pcm_flag[x0][y0].

pcm_alignment_zero_bit is a bit equal to 0.

Table 7-10 – Name association to prediction mode and partitioning type

CuPredMode[x0][y0]	part_mode	IntraSplitFlag	PartMode
MODE_INTRA	0	0	PART_2Nx2N
	1	1	PART_NxN
MODE_INTER	0	0	PART_2Nx2N
	1	0	PART_2NxN
	2	0	PART_Nx2N
	3	0	PART_NxN
	4	0	PART_2NxN_U
	5	0	PART_2NxN_D
	6	0	PART_nLx2N
	7	0	PART_nRx2N

The syntax elements **prev_intra_luma_pred_flag**[x0 + i][y0 + j], **mpm_idx**[x0 + i][y0 + j] and **rem_intra_luma_pred_mode**[x0 + i][y0 + j] specify the intra prediction mode for luma samples. The array indices x0 + i, y0 + j specify the location (x0 + i, y0 + j) of the top-left luma sample of the considered prediction block relative to the top-left luma sample of the picture. When prev_intra_luma_pred_flag[x0 + i][y0 + j] is equal to 1, the intra prediction mode is inferred from a neighbouring intra-predicted prediction unit according to clause 8.4.2.

intra_chroma_pred_mode[x0][y0] specifies the intra prediction mode for chroma samples. The array indices x0, y0 specify the location (x0, y0) of the top-left luma sample of the considered prediction block relative to the top-left luma sample of the picture.

rqt_root_cbf equal to 1 specifies that the transform_tree() syntax structure is present for the current coding unit. rqt_root_cbf equal to 0 specifies that the transform_tree() syntax structure is not present for the current coding unit.

When rqt_root_cbf is not present, its value is inferred to be equal to 1.

7.4.9.6 Prediction unit semantics

mvp_l0_flag[x0][y0] specifies the motion vector predictor index of list 0 where x0, y0 specify the location (x0, y0) of the top-left luma sample of the considered prediction block relative to the top-left luma sample of the picture.

When mvp_l0_flag[x0][y0] is not present, it is inferred to be equal to 0.

mvp_l1_flag[x0][y0] has the same semantics as mvp_l0_flag, with l0 and list 0 replaced by l1 and list 1, respectively.

merge_flag[x0][y0] specifies whether the inter prediction parameters for the current prediction unit are inferred from a neighbouring inter-predicted partition. The array indices x0, y0 specify the location (x0, y0) of the top-left luma sample of the considered prediction block relative to the top-left luma sample of the picture.

When merge_flag[x0][y0] is not present, it is inferred as follows:

- If CuPredMode[x0][y0] is equal to MODE_SKIP, merge_flag[x0][y0] is inferred to be equal to 1.
- Otherwise, merge_flag[x0][y0] is inferred to be equal to 0.

merge_idx[x0][y0] specifies the merging candidate index of the merging candidate list where x0, y0 specify the location (x0, y0) of the top-left luma sample of the considered prediction block relative to the top-left luma sample of the picture.

When merge_idx[x0][y0] is not present, it is inferred to be equal to 0.

inter_pred_idc[x0][y0] specifies whether list0, list1, or bi-prediction is used for the current prediction unit according to Table 7-11. The array indices x0, y0 specify the location (x0, y0) of the top-left luma sample of the considered prediction block relative to the top-left luma sample of the picture.

Table 7-11 – Name association to inter prediction mode

inter_pred_idc	Name of inter_pred_idc	
	(nPbW + nPbH) != 12	(nPbW + nPbH) == 12
0	PRED_L0	PRED_L0
1	PRED_L1	PRED_L1
2	PRED_BI	na

When inter_pred_idc[x0][y0] is not present, it is inferred to be equal to PRED_L0.

ref_idx_l0[x0][y0] specifies the list 0 reference picture index for the current prediction unit. The array indices x0, y0 specify the location (x0, y0) of the top-left luma sample of the considered prediction block relative to the top-left luma sample of the picture.

When ref_idx_l0[x0][y0] is not present it is inferred to be equal to 0.

ref_idx_l1[x0][y0] has the same semantics as ref_idx_l0, with l0 and list 0 replaced by l1 and list 1, respectively.

7.4.9.7 PCM sample semantics

pcm_sample_luma[i] represents a coded luma sample value in the raster scan within the coding unit. The number of bits used to represent each of these samples is PcmBitDepth_Y.

pcm_sample_chroma[i] represents a coded chroma sample value in the raster scan within the coding unit. The first half of the values represent coded Cb samples and the remaining half of the values represent coded Cr samples. The number of bits used to represent each of these samples is PcmBitDepth_C.

7.4.9.8 Transform tree semantics

split_transform_flag[x0][y0][trafoDepth] specifies whether a block is split into four blocks with half horizontal and half vertical size for the purpose of transform coding. The array indices x0, y0 specify the location (x0, y0) of the top-left luma sample of the considered block relative to the top-left luma sample of the picture. The array index trafoDepth specifies the current subdivision level of a coding block into blocks for the purpose of transform coding. trafoDepth is equal to 0 for blocks that correspond to coding blocks.

The variable interSplitFlag is derived as follows:

- If max_transform_hierarchy_depth_inter is equal to 0 and CuPredMode[x0][y0] is equal to MODE_INTER and PartMode is not equal to PART_2Nx2N and trafoDepth is equal to 0, interSplitFlag is set equal to 1.
- Otherwise, interSplitFlag is set equal to 0.

When split_transform_flag[x0][y0][trafoDepth] is not present, it is inferred as follows:

- If one or more of the following conditions are true, the value of split_transform_flag[x0][y0][trafoDepth] is inferred to be equal to 1:
 - log2TrafoSize is greater than MaxTbLog2SizeY.
 - IntraSplitFlag is equal to 1 and trafoDepth is equal to 0.
 - interSplitFlag is equal to 1.
- Otherwise, the value of split_transform_flag[x0][y0][trafoDepth] is inferred to be equal to 0.

cbf_luma[x0][y0][trafoDepth] equal to 1 specifies that the luma transform block contains one or more transform coefficient levels not equal to 0. The array indices x0, y0 specify the location (x0, y0) of the top-left luma sample of the considered transform block relative to the top-left luma sample of the picture. The array index trafoDepth specifies the

current subdivision level of a coding block into blocks for the purpose of transform coding. `trafoDepth` is equal to 0 for blocks that correspond to coding blocks.

When `cbf_luma[x0][y0][trafoDepth]` is not present, it is inferred to be equal to 1.

`cbf_cb[x0][y0][trafoDepth]` equal to 1 specifies that the Cb transform block contains one or more transform coefficient levels not equal to 0. The array indices `x0`, `y0` specify the top-left location (`x0`, `y0`) of the considered transform block. The array index `trafoDepth` specifies the current subdivision level of a coding block into blocks for the purpose of transform coding. `trafoDepth` is equal to 0 for blocks that correspond to coding blocks.

When `cbf_cb[x0][y0][trafoDepth]` is not present, it is inferred to be equal to 0.

`cbf_cr[x0][y0][trafoDepth]` equal to 1 specifies that the Cr transform block contains one or more transform coefficient levels not equal to 0. The array indices `x0`, `y0` specify the top-left location (`x0`, `y0`) of the considered transform block. The array index `trafoDepth` specifies the current subdivision level of a coding block into blocks for the purpose of transform coding. `trafoDepth` is equal to 0 for blocks that correspond to coding blocks.

When `cbf_cr[x0][y0][trafoDepth]` is not present, it is inferred to be equal to 0.

7.4.9.9 Motion vector difference semantics

`abs_mvd_greater0_flag[compIdx]` specifies whether the absolute value of a motion vector component difference is greater than 0.

`abs_mvd_greater1_flag[compIdx]` specifies whether the absolute value of a motion vector component difference is greater than 1.

When `abs_mvd_greater1_flag[compIdx]` is not present, it is inferred to be equal to 0.

`abs_mvd_minus2[compIdx]` plus 2 specifies the absolute value of a motion vector component difference.

When `abs_mvd_minus2[compIdx]` is not present, it is inferred to be equal to -1.

`mvd_sign_flag[compIdx]` specifies the sign of a motion vector component difference as follows:

- If `mvd_sign_flag[compIdx]` is equal to 0, the corresponding motion vector component difference has a positive value.
- Otherwise (`mvd_sign_flag[compIdx]` is equal to 1), the corresponding motion vector component difference has a negative value.

When `mvd_sign_flag[compIdx]` is not present, it is inferred to be equal to 0.

The motion vector difference `lMvd[compIdx]` for `compIdx = 0..1` is derived as follows:

$$\text{lMvd}[\text{compIdx}] = \text{abs_mvd_greater0_flag}[\text{compIdx}] * (\text{abs_mvd_minus2}[\text{compIdx}] + 2) * (1 - 2 * \text{mvd_sign_flag}[\text{compIdx}]) \quad (7-73)$$

The variable `MvdLX[x0][y0][compIdx]`, with `X` being 0 or 1, specifies the difference between a list `X` vector component to be used and its prediction. The value of `MvdLX[x0][y0][compIdx]` shall be in the range of -2^{15} to $2^{15} - 1$, inclusive. The array indices `x0`, `y0` specify the location (`x0`, `y0`) of the top-left luma sample of the considered prediction block relative to the top-left luma sample of the picture. The horizontal motion vector component difference is assigned `compIdx = 0` and the vertical motion vector component is assigned `compIdx = 1`.

- If `refList` is equal to 0, `MvdL0[x0][y0][compIdx]` is set equal to `lMvd[compIdx]` for `compIdx = 0..1`.
- Otherwise (`refList` is equal to 1), `MvdL1[x0][y0][compIdx]` is set equal to `lMvd[compIdx]` for `compIdx = 0..1`.

7.4.9.10 Transform unit semantics

The transform coefficient levels are represented by the arrays `TransCoeffLevel[x0][y0][cIdx][xC][yC]`, which are either specified in clause 7.3.8.11 or inferred as follows. The array indices `x0`, `y0` specify the location (`x0`, `y0`) of the top-left luma sample of the considered transform block relative to the top-left luma sample of the picture. The array index `cIdx` specifies an indicator for the colour component; it is equal to 0 for Y, 1 for Cb, and 2 for Cr. The array indices `xC` and `yC` specify the transform coefficient location (`xC`, `yC`) within the current transform block. When the value of `TransCoeffLevel[x0][y0][cIdx][xC][yC]` is not specified in clause 7.3.8.11, it is inferred to be equal to 0.

`tu_residual_act_flag[x0][y0]` equal to 1 specifies that adaptive colour transform is applied to the residual samples of the current transform unit. `tu_residual_act_flag[x0][y0]` equal to 0 specifies that adaptive colour transform is not applied to the residual samples of the current transform unit. When `tu_residual_act_flag[x0][y0]` is not present, it is inferred to be equal to 0.

When `cu_transquant_bypass_flag` is equal to 1 and `bit_depth_luma_minus8` is not equal to `bit_depth_chroma_minus8`, the value of `tu_residual_act_flag[x0][y0]`, when present, shall be equal to 0.

7.4.9.11 Residual coding semantics

For intra prediction, different scanning orders are used. The variable `scanIdx` specifies which scan order is used where `scanIdx` equal to 0 specifies an up-right diagonal scan order, `scanIdx` equal to 1 specifies a horizontal scan order, and `scanIdx` equal to 2 specifies a vertical scan order. The value of `scanIdx` is derived as follows:

- If `CuPredMode[x0][y0]` is equal to `MODE_INTRA` and one or more of the following conditions are true:
 - `log2TrafoSize` is equal to 2.
 - `log2TrafoSize` is equal to 3 and `cIdx` is equal to 0.
 - `log2TrafoSize` is equal to 3 and `ChromaArrayType` is equal to 3.

`predModeIntra` is derived as follows:

- If `cIdx` is equal to 0, `predModeIntra` is set equal to `IntraPredModeY[x0][y0]`.
- Otherwise, `predModeIntra` is set equal to `IntraPredModeC`.

`scanIdx` is derived as follows:

- If `predModeIntra` is in the range of 6 to 14, inclusive, `scanIdx` is set equal to 2.
 - Otherwise if `predModeIntra` is in the range of 22 to 30, inclusive, `scanIdx` is set equal to 1.
 - Otherwise, `scanIdx` is set equal to 0.
- Otherwise, `scanIdx` is set equal to 0.

`transform_skip_flag[x0][y0][cIdx]` specifies whether a transform is applied to the associated transform block or not: The array indices `x0`, `y0` specify the location (`x0`, `y0`) of the top-left luma sample of the considered transform block relative to the top-left luma sample of the picture. The array index `cIdx` specifies an indicator for the colour component; it is equal to 0 for luma, equal to 1 for Cb and equal to 2 for Cr. `transform_skip_flag[x0][y0][cIdx]` equal to 1 specifies that no transform is applied to the current transform block. `transform_skip_flag[x0][y0][cIdx]` equal to 0 specifies that the decision whether transform is applied to the current transform block or not depends on other syntax elements. When `transform_skip_flag[x0][y0][cIdx]` is not present, it is inferred to be equal to 0.

`explicit_rdpem_flag[x0][y0][cIdx]` specifies whether the residual modification process for blocks using a transform bypass is applied to the associated transform block or not. The array indices `x0`, `y0` specify the location (`x0`, `y0`) of the top-left luma sample of the considered transform block relative to the top-left luma sample of the picture. The array index `cIdx` specifies an indicator for the colour component; it is equal to 0 for luma, equal to 1 for Cb and equal to 2 for Cr. `explicit_rdpem_flag[x0][y0][cIdx]` equal to 1 specifies that the residual modification process is applied to the current transform block. `explicit_rdpem_flag[x0][y0][cIdx]` equal to 0 specifies that no residual modification process is applied to the current transform block. When `explicit_rdpem_flag[x0][y0][cIdx]` is not present, it is inferred to be equal to 0.

`explicit_rdpem_dir_flag[x0][y0][cIdx]` specifies the direction to be used by the residual modification process for the associated transform block. The array indices `x0`, `y0` specify the location (`x0`, `y0`) of the top-left luma sample of the considered transform block relative to the top-left luma sample of the picture. The array index `cIdx` specifies an indicator for the colour component; it is equal to 0 for luma, equal to 1 for Cb and equal to 2 for Cr.

`last_sig_coeff_x_prefix` specifies the prefix of the column position of the last significant coefficient in scanning order within a transform block. The values of `last_sig_coeff_x_prefix` shall be in the range of 0 to (`log2TrafoSize << 1`) – 1, inclusive.

`last_sig_coeff_y_prefix` specifies the prefix of the row position of the last significant coefficient in scanning order within a transform block. The values of `last_sig_coeff_y_prefix` shall be in the range of 0 to (`log2TrafoSize << 1`) – 1, inclusive.

`last_sig_coeff_x_suffix` specifies the suffix of the column position of the last significant coefficient in scanning order within a transform block. The values of `last_sig_coeff_x_suffix` shall be in the range of 0 to (1 << ((`last_sig_coeff_x_prefix` >> 1) – 1)) – 1, inclusive.

The column position of the last significant coefficient in scanning order within a transform block `LastSignificantCoeffX` is derived as follows:

- If `last_sig_coeff_x_suffix` is not present, the following applies:

$$\text{LastSignificantCoeffX} = \text{last_sig_coeff_x_prefix} \quad (7-74)$$

- Otherwise (last_sig_coeff_x_suffix is present), the following applies:

$$\text{LastSignificantCoeffX} = (1 \ll ((\text{last_sig_coeff_x_prefix} \gg 1) - 1)) * (2 + (\text{last_sig_coeff_x_prefix} \& 1)) + \text{last_sig_coeff_x_suffix} \quad (7-75)$$

last_sig_coeff_y_suffix specifies the suffix of the row position of the last significant coefficient in scanning order within a transform block. The values of last_sig_coeff_y_suffix shall be in the range of 0 to $(1 \ll ((\text{last_sig_coeff_y_prefix} \gg 1) - 1)) - 1$, inclusive.

The row position of the last significant coefficient in scanning order within a transform block LastSignificantCoeffY is derived as follows:

- If last_sig_coeff_y_suffix is not present, the following applies:

$$\text{LastSignificantCoeffY} = \text{last_sig_coeff_y_prefix} \quad (7-76)$$

- Otherwise (last_sig_coeff_y_suffix is present), the following applies:

$$\text{LastSignificantCoeffY} = (1 \ll ((\text{last_sig_coeff_y_prefix} \gg 1) - 1)) * (2 + (\text{last_sig_coeff_y_prefix} \& 1)) + \text{last_sig_coeff_y_suffix} \quad (7-77)$$

When scanIdx is equal to 2, the coordinates are swapped as follows:

$$(\text{LastSignificantCoeffX}, \text{LastSignificantCoeffY}) = \text{Swap}(\text{LastSignificantCoeffX}, \text{LastSignificantCoeffY}) \quad (7-78)$$

coded_sub_block_flag[xS][yS] specifies the following for the sub-block at location (xS, yS) within the current transform block, where a sub-block is a (4x4) array of 16 transform coefficient levels:

- If coded_sub_block_flag[xS][yS] is equal to 0, the 16 transform coefficient levels of the sub-block at location (xS, yS) are inferred to be equal to 0.
- Otherwise (coded_sub_block_flag[xS][yS] is equal to 1), the following applies:
 - If (xS, yS) is equal to (0, 0) and (LastSignificantCoeffX, LastSignificantCoeffY) is not equal to (0, 0), at least one of the 16 sig_coeff_flag syntax elements is present for the sub-block at location (xS, yS).
 - Otherwise, at least one of the 16 transform coefficient levels of the sub-block at location (xS, yS) has a non-zero value.

When coded_sub_block_flag[xS][yS] is not present, it is inferred as follows:

- If one or more of the following conditions are true, coded_sub_block_flag[xS][yS] is inferred to be equal to 1:
 - (xS, yS) is equal to (0, 0).
 - (xS, yS) is equal to (LastSignificantCoeffX >> 2, LastSignificantCoeffY >> 2).
- Otherwise, coded_sub_block_flag[xS][yS] is inferred to be equal to 0.

sig_coeff_flag[xC][yC] specifies for the transform coefficient location (xC, yC) within the current transform block whether the corresponding transform coefficient level at the location (xC, yC) is non-zero as follows:

- If sig_coeff_flag[xC][yC] is equal to 0, the transform coefficient level at the location (xC, yC) is set equal to 0.
- Otherwise (sig_coeff_flag[xC][yC] is equal to 1), the transform coefficient level at the location (xC, yC) has a non-zero value.

When sig_coeff_flag[xC][yC] is not present, it is inferred as follows:

- If (xC, yC) is the last significant location (LastSignificantCoeffX, LastSignificantCoeffY) in scan order or all of the following conditions are true, sig_coeff_flag[xC][yC] is inferred to be equal to 1:
 - (xC & 3, yC & 3) is equal to (0, 0).
 - inferSbDcSigCoeffFlag is equal to 1.
 - coded_sub_block_flag[xS][yS] is equal to 1.
- Otherwise, sig_coeff_flag[xC][yC] is inferred to be equal to 0.

coeff_abs_level_greater1_flag[n] specifies for the scanning position *n* whether there are absolute values of transform coefficient levels greater than 1.

When **coeff_abs_level_greater1_flag[n]** is not present, it is inferred to be equal to 0.

coeff_abs_level_greater2_flag[n] specifies for the scanning position *n* whether there are absolute values of transform coefficient levels greater than 2.

When **coeff_abs_level_greater2_flag[n]** is not present, it is inferred to be equal to 0.

coeff_sign_flag[n] specifies the sign of a transform coefficient level for the scanning position *n* as follows:

- If **coeff_sign_flag[n]** is equal to 0, the corresponding transform coefficient level has a positive value.
- Otherwise (**coeff_sign_flag[n]** is equal to 1), the corresponding transform coefficient level has a negative value.

When **coeff_sign_flag[n]** is not present, it is inferred to be equal to 0.

coeff_abs_level_remaining[n] is the remaining absolute value of a transform coefficient level that is coded with Golomb-Rice code at the scanning position *n*. When **coeff_abs_level_remaining[n]** is not present, it is inferred to be equal to 0.

It is a requirement of bitstream conformance that the value of **coeff_abs_level_remaining[n]** shall be constrained such that the corresponding value of **TransCoeffLevel[x0][y0][cIdx][xC][yC]** is in the range of **CoeffMin_Y** to **CoeffMax_Y**, inclusive, for **cIdx** equal to 0 and in the range of **CoeffMin_C** to **CoeffMax_C**, inclusive, for **cIdx** not equal to 0.

7.4.9.12 Cross-component prediction semantics

log2_res_scale_abs_plus1[c] minus 1 specifies the base 2 logarithm of the magnitude of the scaling factor **ResScaleVal** used in cross-component residual prediction. When not present, **log2_res_scale_abs_plus1** is inferred to be equal to 0.

res_scale_sign_flag[c] specifies the sign of the scaling factor used in cross-component residual prediction as follows:

- If **res_scale_sign_flag[c]** is equal to 0, the corresponding **ResScaleVal** has a positive value.
- Otherwise (**res_scale_sign_flag[c]** is equal to 1), the corresponding **ResScaleVal** has a negative value.

The variable **ResScaleVal[cIdx][x0][y0]** specifies the scaling factor used in cross-component residual prediction. The array indices *x0*, *y0* specify the location (*x0*, *y0*) of the top-left luma sample of the considered transform block relative to the top-left luma sample of the picture. The array index *cIdx* specifies an indicator for the colour component; it is equal to 1 for Cb and equal to 2 for Cr.

The variable **ResScaleVal[cIdx][x0][y0]** is derived as follows:

- If **log2_res_scale_abs_plus1[cIdx – 1]** is equal to 0, the following applies:

$$\text{ResScaleVal}[\text{cIdx}][\text{x0}][\text{y0}] = 0 \quad (7-79)$$

- Otherwise (**log2_res_scale_abs_plus1[cIdx – 1]** is not equal to 0), the following applies:

$$\text{ResScaleVal}[\text{cIdx}][\text{x0}][\text{y0}] = (1 \ll (\text{log2_res_scale_abs_plus1}[\text{cIdx} - 1] - 1)) * (1 - 2 * \text{res_scale_sign_flag}[\text{cIdx} - 1]) \quad (7-80)$$

7.4.9.13 Palette semantics

In the following semantics, the array indices *x0*, *y0* specify the location (*x0*, *y0*) of the top-left luma sample of the considered coding block relative to the top-left luma sample of the picture.

The predictor palette consists of palette entries from previous coding units that are used to predict the entries in the current palette.

The variable **PredictorPaletteSize** specifies the size of the predictor palette. **PredictorPaletteSize** is derived as specified in clause 8.4.4.2.7.

The variable **PalettePredictorEntryReuseFlags[i]** equal to 1 specifies that the *i*-th entry in the predictor palette is reused in the current palette. **PalettePredictorEntryReuseFlags[i]** equal to 0 specifies that the *i*-th entry in the predictor palette is not an entry in the current palette. All elements of the array **PalettePredictorEntryReuseFlags[i]** are initialized to 0.

palette_predictor_run is used to determine the number of zeros that precede a non-zero entry in the array **PalettePredictorEntryReuseFlags**.

It is a requirement of bitstream conformance that the value of **palette_predictor_run** shall be in the range of 0 to (**PredictorPaletteSize** – **predictorEntryIdx**), inclusive, where **predictorEntryIdx** corresponds to the current position in the

array `PalettePredictorEntryReuseFlags`. The variable `NumPredictedPaletteEntries` specifies the number of entries in the current palette that are reused from the predictor palette. The value of `NumPredictedPaletteEntries` shall be in the range of 0 to `palette_max_size`, inclusive.

num_signalled_palette_entries specifies the number of entries in the current palette that are explicitly signalled.

When `num_signalled_palette_entries` is not present, it is inferred to be equal to 0.

The variable `CurrentPaletteSize` specifies the size of the current palette and is derived as follows:

$$\text{CurrentPaletteSize} = \text{NumPredictedPaletteEntries} + \text{num_signalled_palette_entries} \quad (7-81)$$

The value of `CurrentPaletteSize` shall be in the range of 0 to `palette_max_size`, inclusive.

new_palette_entries[cIdx][i] specifies the value for the *i*-th signalled palette entry for the colour component *cIdx*.

The variable `PredictorPaletteEntries[cIdx][i]` specifies the *i*-th element in the predictor palette for the colour component *cIdx*.

The variable `CurrentPaletteEntries[cIdx][i]` specifies the *i*-th element in the current palette for the colour component *cIdx* and is derived as follows:

```

numComps = ( ChromaArrayType == 0 ) ? 1 : 3
numPredictedPaletteEntries = 0
for( i = 0; i < PredictorPaletteSize; i++ )
    if( PalettePredictorEntryReuseFlags[ i ] ) {
        for( cIdx = 0; cIdx < numComps; cIdx++ )
            CurrentPaletteEntries[ cIdx ][ numPredictedPaletteEntries ] =
PredictorPaletteEntries[ cIdx ][ i ]
            numPredictedPaletteEntries++
    }
for( cIdx = 0; cIdx < numComps; cIdx++ )
    for( i = 0; i < num_signalled_palette_entries; i++ )
        CurrentPaletteEntries[ cIdx ][ numPredictedPaletteEntries + i ] = new_palette_entries[ cIdx ][ i ]

```

(7-82)

palette_escape_val_present_flag equal to 1 specifies that the current coding unit contains at least one escape-coded sample. `palette_escape_val_present_flag` equal to 0 specifies that there are no escape-coded samples in the current coding unit. When not present, the value of `palette_escape_val_present_flag` is inferred to be equal to 1.

The variable `MaxPaletteIndex` specifies the maximum possible value for a palette index for the current coding unit. The value of `MaxPaletteIndex` is set equal to `CurrentPaletteSize - 1 + palette_escape_val_present_flag`.

num_palette_indices_minus1 plus 1 is the number of palette indices explicitly signalled or inferred for the current block.

When `num_palette_indices_minus1` is not present, it is inferred to be equal to 0.

palette_idx_idc is an indication of an index to the array represented by `CurrentPaletteEntries`. The value of `palette_idx_idc` shall be in the range of 0 to `MaxPaletteIndex`, inclusive, for the first index in the block and in the range of 0 to (`MaxPaletteIndex - 1`), inclusive, for the remaining indices in the block.

When `palette_idx_idc` is not present, it is inferred to be equal to 0.

The variable `PaletteIndexIdc[i]` stores the *i*-th `palette_idx_idc` explicitly signalled or inferred. All elements of the array `PaletteIndexIdc[i]` are initialized to 0.

copy_above_indices_for_final_run_flag equal to 1 specifies that the palette indices of the last positions in the coding unit are copied from the palette indices in the row above. **copy_above_indices_for_final_run_flag** equal to 0 specifies that the palette indices of the last positions in the coding unit are copied from `PaletteIndexIdc[num_palette_indices_minus1]`.

When **copy_above_indices_for_final_run_flag** is not present, it is inferred to be equal to 0.

palette_transpose_flag equal to 1 specifies that the transpose process is applied to the reconstructed sample array at the output of palette mode decoding as specified in clause 8.4.4.2.7 in the current coding unit. **palette_transpose_flag** equal to 0 specifies that the transpose process is not applied to the reconstructed sample array at the output of palette mode decoding clause 8.4.4.2.7 in the current coding unit. When not present, the value of **palette_transpose_flag** is inferred to be equal to 0.

copy_above_palette_indices_flag equal to 1 specifies that the palette index is equal to the palette index at the same location in the row above. **copy_above_palette_indices_flag** equal to 0 specifies that an indication of the palette index of the sample is coded in the bitstream or inferred.

The variable `CopyAboveIndicesFlag[xC][yC]` equal to 1 specifies that the palette index is copied from the palette index in the row above. `CopyAboveIndicesFlag[xC][yC]` equal to 0 specifies that the palette index is explicitly coded in the bitstream or inferred. The array indices `xC`, `yC` specify the location (`xC`, `yC`) of the sample relative to the top-left luma sample of the picture.

The variable `PaletteIndexMap[xC][yC]` specifies a palette index, which is an index to the array represented by `CurrentPaletteEntries`. The array indices `xC`, `yC` specify the location (`xC`, `yC`) of the sample relative to the top-left luma sample of the picture. The value of `PaletteIndexMap[xC][yC]` shall be in the range of 0 to `MaxPaletteIndex`, inclusive.

The variable `adjustedRefPaletteIndex` is derived as follows:

```
adjustedRefPaletteIndex = MaxPaletteIndex + 1
log2BlkSize = Log2( nCbs ) - 2
if( PaletteScanPos > 0 ) {
    xcPrev = x0 + ScanOrder[ log2BlkSize ][ 3 ][ PaletteScanPos - 1 ][ 0 ]
    ycPrev = y0 + ScanOrder[ log2BlkSize ][ 3 ][ PaletteScanPos - 1 ][ 1 ]
    if( CopyAboveIndicesFlag[ xcPrev ][ ycPrev ] == 0 )
        adjustedRefPaletteIndex = PaletteIndexMap[ xcPrev ][ ycPrev ]
    else
        adjustedRefPaletteIndex = PaletteIndexMap[ xC ][ yC - 1 ]
}
```

(7-83)

When `CopyAboveIndicesFlag[xC][yC]` is equal to 0, the variable `CurrPaletteIndex` is derived as follows:

```
if( CurrPaletteIndex >= adjustedRefPaletteIndex )
    CurrPaletteIndex++
```

(7-84)

palette_run_prefix, when present, is used in the derivation of the variable `PaletteRunMinus1`.

palette_run_suffix is used in the derivation of the variable `PaletteRunMinus1`. When not present, the value of **palette_run_suffix** is inferred to be equal to 0.

When `RunToEnd` is equal to 0, the variable `PaletteRunMinus1` is derived as follows:

- If `PaletteMaxRunMinus1` is equal to 0, `PaletteRunMinus1` is set equal to 0.
- Otherwise (`PaletteMaxRunMinus1` is greater than 0) the following applies:
 - If **palette_run_prefix** is less than 2, the following applies:

```
PaletteRunMinus1 = palette_run_prefix
```

(7-85)

- Otherwise (palette_run_prefix is greater than or equal to 2), the following applies:

$$\begin{aligned}\text{PrefixOffset} &= 1 \ll (\text{palette_run_prefix} - 1) \\ \text{PaletteRunMinus1} &= \text{PrefixOffset} + \text{palette_run_suffix}\end{aligned}\quad (7-86)$$

The variable PaletteRunMinus1 is used as follows:

- If CopyAboveIndicesFlag[xC][yC] is equal to 0, PaletteRunMinus1 specifies the number of consecutive locations minus 1 with the same palette index.
- Otherwise, PaletteRunMinus1 specifies the number of consecutive locations minus 1 with the same palette index as used in the corresponding position in the row above.

When RunToEnd is equal to 0, the variable PaletteMaxRunMinus1 represents the maximum possible value for PaletteRunMinus1 and it is a requirement of bitstream conformance that the value of PaletteMaxRunMinus1 shall be greater than or equal to 0.

palette_escape_val specifies the quantized escape-coded sample value for a component.

The variable PaletteEscapeVal[cIdx][xC][yC] specifies the escape value of a sample for which PaletteIndexMap[xC][yC] is equal to MaxPaletteIndex and palette_escape_val_present_flag is equal to 1. The array index cIdx specifies the colour component. The array indices xC, yC specify the location (xC, yC) of the sample relative to the top-left luma sample of the picture.

It is a requirement of bitstream conformance that PaletteEscapeVal[cIdx][xC][yC] shall be in the range of 0 to $(1 \ll (\text{BitDepth}_Y + 1)) - 1$, inclusive, for cIdx equal to 0, and in the range of 0 to $(1 \ll (\text{BitDepth}_C + 1)) - 1$, inclusive, for cIdx not equal to 0.

7.4.9.14 Delta QP semantics

cu_qp_delta_abs, when present, specifies the absolute value of the difference CuQpDeltaVal between the luma quantization parameter of the current coding unit and its prediction.

cu_qp_delta_sign_flag, when present, specifies the sign of the difference CuQpDeltaVal between the luma quantization parameter of the current coding unit and its prediction.

It is a requirement of bitstream conformance that the value of CuQpDeltaVal shall be in the range of $-(26 + \text{QpBdOffsetY} / 2)$ to $+(25 + \text{QpBdOffsetY} / 2)$, inclusive.

7.4.9.15 Chroma QP offset semantics

cu_chroma_qp_offset_flag, when present and equal to 1, specifies that an entry in the cb_qp_offset_list[] is used to determine the value of CuQpOffsetCb and a corresponding entry in the cr_qp_offset_list[] is used to determine the value of CuQpOffsetCr. cu_chroma_qp_offset_flag equal to 0 specifies that these lists are not used to determine the values of CuQpOffsetCb and CuQpOffsetCr.

cu_chroma_qp_offset_idx, when present, specifies the index into the cb_qp_offset_list[] and cr_qp_offset_list[] that is used to determine the value of CuQpOffsetCb and CuQpOffsetCr. When present, the value of cu_chroma_qp_offset_idx shall be in the range of 0 to chroma_qp_offset_list_len_minus1, inclusive. When not present, the value of cu_chroma_qp_offset_idx is inferred to be equal to 0.

When cu_chroma_qp_offset_flag is present, the following applies:

- The variable IsCuChromaQpOffsetCoded is set equal to 1.
- The variables CuQpOffsetCb and CuQpOffsetCr are derived as follows:
 - If cu_chroma_qp_offset_flag is equal to 1, the following applies:

$$\text{CuQpOffsetCb} = \text{cb_qp_offset_list}[\text{cu_chroma_qp_offset_idx}] \quad (7-87)$$

$$\text{CuQpOffsetCr} = \text{cr_qp_offset_list}[\text{cu_chroma_qp_offset_idx}] \quad (7-88)$$

- Otherwise (cu_chroma_qp_offset_flag is equal to 0), CuQpOffsetCb and CuQpOffsetCr are both set equal to 0.

NOTE – When cu_chroma_qp_offset_enabled_flag is equal to 0, CuQpOffsetCb and CuQpOffsetCr are not modified after being initialized to 0 for the slice as specified in clause 7.4.7.1.

8 Decoding process

8.1 General decoding process

8.1.1 General

Input to this process is a bitstream. Output of this process is a list of decoded pictures.

The decoding process is specified such that all decoders that conform to a specified profile, tier and level will produce numerically identical cropped decoded output pictures when invoking the decoding process associated with that profile for a bitstream conforming to that profile, tier and level. Any decoding process that produces identical cropped decoded output pictures to those produced by the process described herein (with the correct output order or output timing, as specified) conforms to the decoding process requirements of this Specification.

NOTE 1 – For the purpose of best-effort decoding, a decoder that conforms to a particular profile at a given tier and level may additionally decode some bitstreams conforming to a different tier, level or profile without necessarily using a decoding process that produces numerically identical cropped decoded output pictures to those produced by the process specified herein (without claiming conformance to the other profile, tier and level).

At the beginning of decoding a coded video sequence group (CVSG), after activating the VPS RBSP that is active for the entire CVSG and before decoding any VCL NAL units of the CVSG, clause 8.1.2 is invoked with the CVSG as input.

8.1.2 CVSG decoding process

Input to this process is a CVSG. Output of this process is a list of decoded pictures.

The layer identifier list TargetDecLayerIdList, which specifies the list of nuh_layer_id values, in increasing order of nuh_layer_id values, of the NAL units to be decoded, is specified as follows:

- If some external means, not specified in this Specification, is available to set TargetDecLayerIdList, TargetDecLayerIdList is set by the external means.
- Otherwise, if the decoding process is invoked in a bitstream conformance test as specified in clause C.1, TargetDecLayerIdList is set as specified in clause C.1.
- Otherwise, TargetDecLayerIdList contains only one nuh_layer_id value that is equal to 0.

The variable HighestTid, which identifies the highest temporal sub-layer to be decoded, is specified as follows:

- If some external means, not specified in this Specification, is available to set HighestTid, HighestTid is set by the external means.
- Otherwise, if the decoding process is invoked in a bitstream conformance test as specified in clause C.1, HighestTid is set as specified in clause C.1.
- Otherwise, HighestTid is set equal to sps_max_sub_layers_minus1.

The variable SubPicHrdFlag is specified as follows:

- If the decoding process is invoked in a bitstream conformance test as specified in clause C.1, SubPicHrdFlag is set as specified in clause C.1.
- Otherwise, SubPicHrdFlag is set equal to (SubPicHrdPreferredFlag && sub_pic_hrd_params_present_flag).

The sub-bitstream extraction process as specified in clause 10 is applied with the CVSG, HighestTid and TargetDecLayerIdList as inputs, and the output is assigned to a bitstream referred to as BitstreamToDecode.

Clause 8.1.3 is repeatedly invoked for each coded picture with nuh_layer_id equal to 0 in BitstreamToDecode in decoding order.

8.1.3 Decoding process for a coded picture with nuh_layer_id equal to 0

The decoding processes specified in this clause apply to each coded picture with nuh_layer_id equal to 0, referred to as the current picture and denoted by the variable CurrPic, in BitstreamToDecode.

Depending on the value of chroma_format_idc, the number of sample arrays of the current picture is as follows:

- If chroma_format_idc is equal to 0, the current picture consists of 1 sample array S_L.
- Otherwise (chroma_format_idc is not equal to 0), the current picture consists of 3 sample arrays S_L, S_{Cb}, S_{Cr}.

The decoding process for the current picture takes as inputs the syntax elements and upper-case variables from clause 7. When interpreting the semantics of each syntax element in each NAL unit, the term "the bitstream" (or part thereof, e.g., a CVS of the bitstream) refers to BitstreamToDecode (or part thereof).

When the current picture is a BLA picture that has nal_unit_type equal to BLA_W_LP or is a CRA picture, the following applies:

- If some external means not specified in this Specification is available to set the variable UseAltCpbParamsFlag to a value, UseAltCpbParamsFlag is set equal to the value provided by the external means.
- Otherwise, the value of UseAltCpbParamsFlag is set equal to 0.

When the current picture is an IRAP picture, the following applies:

- If the current picture is an IDR picture, a BLA picture, the first picture in the bitstream in decoding order, or the first picture that follows an end of sequence NAL unit in decoding order, the variable NoRaslOutputFlag is set equal to 1.
- Otherwise, if some external means not specified in this Specification is available to set the variable HandleCraAsBlaFlag to a value for the current picture, the variable HandleCraAsBlaFlag is set equal to the value provided by the external means and the variable NoRaslOutputFlag is set equal to HandleCraAsBlaFlag.
- Otherwise, the variable HandleCraAsBlaFlag is set equal to 0 and the variable NoRaslOutputFlag is set equal to 0.

Depending on the value of separate_colour_plane_flag, the decoding process is structured as follows:

- If separate_colour_plane_flag is equal to 0, the decoding process is invoked a single time with the current picture being the output.
- Otherwise (separate_colour_plane_flag is equal to 1), the decoding process is invoked three times. Inputs to the decoding process are all NAL units of the coded picture with identical value of colour_plane_id. The decoding process of NAL units with a particular value of colour_plane_id is specified as if only a CVS with monochrome colour format with that particular value of colour_plane_id would be present in the bitstream. The output of each of the three decoding processes is assigned to one of the 3 sample arrays of the current picture, with the NAL units with colour_plane_id equal to 0, 1 and 2 being assigned to S_L, S_{Cb} and S_{Cr}, respectively.

NOTE 1 – The variable ChromaArrayType is derived as equal to 0 when separate_colour_plane_flag is equal to 1 and chroma_format_idc is equal to 3. In the decoding process, the value of this variable is evaluated resulting in operations identical to that of monochrome pictures (when chroma_format_idc is equal to 0).

The decoding process operates as follows for the current picture CurrPic:

1. The decoding of NAL units is specified in clause 8.2.
2. The processes in clause 8.3 specify the following decoding processes using syntax elements in the slice segment layer and above:
 - Variables and functions relating to picture order count are derived as specified in clause 8.3.1. This needs to be invoked only for the first slice segment of a picture.
 - The decoding process for RPS in clause 8.3.2 is invoked, wherein reference pictures may be marked as "unused for reference" or "used for long-term reference". This needs to be invoked only for the first slice segment of a picture.
 - A picture storage buffer in the DPB is allocated for storage of the decoded sample values of the current picture after the invocation of the in-loop filter process as specified in clause 8.7. This version of the current decoded picture is referred to as the current decoded picture after the invocation of the in-loop filter process. When TwoVersionsOfCurrDecPicFlag is equal to 0 and pps_curr_pic_ref_enabled_flag is equal to 1, this picture storage buffer is marked as "used for long-term reference". When TwoVersionsOfCurrDecPicFlag is equal to 1, another picture storage buffer in the DPB is allocated for storage of the decoded sample values of the current picture immediately before the invocation of the in-loop filter process as specified in clause 8.7, and is marked as "used for long-term reference". This version of the current decoded picture is referred to as the current decoded picture before the invocation of the in-loop filter process. This needs to be invoked only for the first slice segment of a picture.

NOTE 2 – When TwoVersionsOfCurrDecPicFlag is equal to 0, there is only one version of the current decoded picture. In this case, if pps_curr_pic_ref_enabled_flag is equal to 1, the current decoded picture is marked as "used for long-term reference" during the decoding of the current picture and will be marked as "used for short-term reference" at the end of the decoding of the current picture, otherwise it is not marked at all during the decoding of the current picture and will be marked as "used for short-term reference" at the end of the decoding of the current picture. When TwoVersionsOfCurrDecPicFlag is equal to 1, there are two versions of the current decoded picture, one of which is marked as "used for long-term reference" during the decoding of the current picture and will be marked as "unused for reference" at the end of the decoding of the current picture, and the

other version is not marked at all during the decoding of the current picture and will be marked as "used for short-term reference" at the end of the decoding of the current picture.

- When the current picture is a BLA picture or is a CRA picture with NoRaslOutputFlag equal to 1, the decoding process for generating unavailable reference pictures specified in clause 8.3.3 is invoked, which needs to be invoked only for the first slice segment of a picture.
 - PicOutputFlag is set as follows:
 - If the current picture is a RASL picture and NoRaslOutputFlag of the associated IRAP picture is equal to 1, PicOutputFlag is set equal to 0.
 - Otherwise, PicOutputFlag is set equal to pic_output_flag.
 - At the beginning of the decoding process for each P or B slice, the decoding process for reference picture lists construction specified in clause 8.3.4 is invoked for derivation of reference picture list 0 (RefPicList0) and, when decoding a B slice, reference picture list 1 (RefPicList1), and the decoding process for collocated picture and no backward prediction flag specified in clause 8.3.5 is invoked for derivation of the variables ColPic and NoBackwardPredFlag.
3. The processes in clauses 8.4, 8.5, 8.6 and 8.7 specify decoding processes using syntax elements in all syntax structure layers. It is a requirement of bitstream conformance that the coded slices of the picture shall contain slice segment data for every CTU of the picture, such that the division of the picture into slices, the division of the slices into slice segments and the division of the slice segments into CTUs each forms a partitioning of the picture.
 4. After all slices of the current picture have been decoded, the current decoded picture after the invocation of the in-loop filter process as specified in clause 8.7 is marked as "used for short-term reference". When TwoVersionsOfCurrDecPicFlag is equal to 1, the current decoded picture before the invocation of the in-loop filter process as specified in clause 8.7 is marked as "unused for reference".

8.2 NAL unit decoding process

Inputs to this process are NAL units of the current picture and their associated non-VCL NAL units.

Outputs of this process are the parsed RBSP syntax structures encapsulated within the NAL units.

The decoding process for each NAL unit extracts the RBSP syntax structure from the NAL unit and then parses the RBSP syntax structure.

8.3 Slice decoding process

8.3.1 Decoding process for picture order count

Output of this process is PicOrderCntVal, the picture order count of the current picture.

Picture order counts are used to identify pictures, for deriving motion parameters in merge mode and motion vector prediction, and for decoder conformance checking (see clause C.5).

Each coded picture is associated with a picture order count variable, denoted as PicOrderCntVal.

When the current picture is not an IRAP picture with NoRaslOutputFlag equal to 1, the variables prevPicOrderCntLsb and prevPicOrderCntMsb are derived as follows:

- Let prevTid0Pic be the previous picture in decoding order that has TemporalId equal to 0 and that is not a RASL, RADL or SLNR picture.
- The variable prevPicOrderCntLsb is set equal to slice_pic_order_cnt_lsb of prevTid0Pic.
- The variable prevPicOrderCntMsb is set equal to PicOrderCntMsb of prevTid0Pic.

The variable PicOrderCntMsb of the current picture is derived as follows:

- If the current picture is an IRAP picture with NoRaslOutputFlag equal to 1, PicOrderCntMsb is set equal to 0.
- Otherwise, PicOrderCntMsb is derived as follows:

$$\begin{aligned}
 & \text{if} ((\text{slice_pic_order_cnt_lsb} < \text{prevPicOrderCntLsb}) \ \&\& \\
 & \quad ((\text{prevPicOrderCntLsb} - \text{slice_pic_order_cnt_lsb}) \geq (\text{MaxPicOrderCntLsb} / 2))) \\
 & \quad \text{PicOrderCntMsb} = \text{prevPicOrderCntMsb} + \text{MaxPicOrderCntLsb} \\
 & \text{else if} ((\text{slice_pic_order_cnt_lsb} > \text{prevPicOrderCntLsb}) \ \&\& \\
 & \quad ((\text{slice_pic_order_cnt_lsb} - \text{prevPicOrderCntLsb}) > (\text{MaxPicOrderCntLsb} / 2)))
 \end{aligned} \tag{8-1}$$

```

    PicOrderCntMsb = prevPicOrderCntMsb – MaxPicOrderCntLsb
else
    PicOrderCntMsb = prevPicOrderCntMsb

```

PicOrderCntVal is derived as follows:

$$\text{PicOrderCntVal} = \text{PicOrderCntMsb} + \text{slice_pic_order_cnt_lsb} \quad (8-2)$$

NOTE 1 – All IDR pictures will have PicOrderCntVal equal to 0 since slice_pic_order_cnt_lsb is inferred to be 0 for IDR pictures and prevPicOrderCntLsb and prevPicOrderCntMsb are both set equal to 0.

The value of PicOrderCntVal shall be in the range of -2^{31} to $2^{31} - 1$, inclusive. In one CVS, the PicOrderCntVal values for any two coded pictures shall not be the same.

The function PicOrderCnt(picX) is specified as follows:

$$\text{PicOrderCnt}(\text{picX}) = \text{PicOrderCntVal of the picture picX} \quad (8-3)$$

The function DiffPicOrderCnt(picA, picB) is specified as follows:

$$\text{DiffPicOrderCnt}(\text{picA}, \text{picB}) = \text{PicOrderCnt}(\text{picA}) - \text{PicOrderCnt}(\text{picB}) \quad (8-4)$$

The bitstream shall not contain data that result in values of DiffPicOrderCnt(picA, picB) used in the decoding process that are not in the range of -2^{15} to $2^{15} - 1$, inclusive.

NOTE 2 – Let X be the current picture and Y and Z be two other pictures in the same CVS, Y and Z are considered to be in the same output order direction from X when both DiffPicOrderCnt(X, Y) and DiffPicOrderCnt(X, Z) are positive or both are negative.

8.3.2 Decoding process for reference picture set

This process is invoked once per picture, after decoding of a slice header but prior to the decoding of any coding unit and prior to the decoding process for reference picture list construction for the slice as specified in clause 8.3.4. This process may result in one or more reference pictures in the DPB being marked as "unused for reference" or "used for long-term reference".

NOTE 1 – The RPS is an absolute description of the reference pictures used in the decoding process of the current and future coded pictures. The RPS signalling is explicit in the sense that all reference pictures included in the RPS are listed explicitly.

A decoded picture in the DPB can be marked as "unused for reference", "used for short-term reference" or "used for long-term reference", but only one among these three at any given moment during the operation of the decoding process. Assigning one of these markings to a picture implicitly removes another of these markings when applicable. When a picture is referred to as being marked as "used for reference", this collectively refers to the picture being marked as "used for short-term reference" or "used for long-term reference" (but not both).

The variable currPicLayerId is set equal to nuh_layer_id of the current picture.

When the current picture is an IRAP picture with NoRasOutputFlag equal to 1, all reference pictures with nuh_layer_id equal to currPicLayerId currently in the DPB (if any) are marked as "unused for reference".

Short-term reference pictures are identified by their PicOrderCntVal values. Long-term reference pictures are identified either by their PicOrderCntVal values or their slice_pic_order_cnt_lsb values.

Five lists of picture order count values are constructed to derive the RPS. These five lists are PocStCurrBefore, PocStCurrAfter, PocStFoll, PocLtCurr and PocLtFoll, with NumPocStCurrBefore, NumPocStCurrAfter, NumPocStFoll, NumPocLtCurr and NumPocLtFoll number of elements, respectively. The five lists and the five variables are derived as follows:

- If the current picture is an IDR picture, PocStCurrBefore, PocStCurrAfter, PocStFoll, PocLtCurr and PocLtFoll are all set to be empty, and NumPocStCurrBefore, NumPocStCurrAfter, NumPocStFoll, NumPocLtCurr and NumPocLtFoll are all set equal to 0.
- Otherwise, the following applies:

```

for( i = 0, j = 0, k = 0; i < NumNegativePics[ CurrRpsIdx ]; i++ )
    if( UsedByCurrPicS0[ CurrRpsIdx ][ i ] )
        PocStCurrBefore[ j++ ] = PicOrderCntVal + DeltaPocS0[ CurrRpsIdx ][ i ]
    else
        PocStFoll[ k++ ] = PicOrderCntVal + DeltaPocS0[ CurrRpsIdx ][ i ]
NumPocStCurrBefore = j

```

```

for( i = 0, j = 0; i < NumPositivePics[ CurrRpsIdx ]; i++ )
    if( UsedByCurrPicS1[ CurrRpsIdx ][ i ] )
        PocStCurrAfter[ j++ ] = PicOrderCntVal + DeltaPocS1[ CurrRpsIdx ][ i ]
    else
        PocStFoll[ k++ ] = PicOrderCntVal + DeltaPocS1[ CurrRpsIdx ][ i ]
NumPocStCurrAfter = j
NumPocStFoll = k
for( i = 0, j = 0, k = 0; i < num_long_term_sps + num_long_term_pics; i++ ) {
    pocLt = PocLsbLt[ i ]
    if( delta_poc_msb_present_flag[ i ] )
        pocLt += PicOrderCntVal - DeltaPocMsbCycleLt[ i ] * MaxPicOrderCntLsb -
                ( PicOrderCntVal & ( MaxPicOrderCntLsb - 1 ) )
    if( UsedByCurrPicLt[ i ] ) {
        PocLtCurr[ j ] = pocLt
        CurrDeltaPocMsbPresentFlag[ j++ ] = delta_poc_msb_present_flag[ i ]
    } else {
        PocLtFoll[ k ] = pocLt
        FollDeltaPocMsbPresentFlag[ k++ ] = delta_poc_msb_present_flag[ i ]
    }
}
NumPocLtCurr = j
NumPocLtFoll = k

```

(8-5)

where PicOrderCntVal is the picture order count of the current picture as specified in clause 8.3.1.

NOTE 2 – A value of CurrRpsIdx in the range of 0 to num_short_term_ref_pic_sets – 1, inclusive, indicates that a candidate short-term RPS from the active SPS for the current layer is being used, where CurrRpsIdx is the index of the candidate short-term RPS into the list of candidate short-term RPSs signalled in the active SPS for the current layer. CurrRpsIdx equal to num_short_term_ref_pic_sets indicates that the short-term RPS of the current picture is directly signalled in the slice header.

For each i in the range of 0 to NumPocLtCurr – 1, inclusive, when CurrDeltaPocMsbPresentFlag[i] is equal to 1, it is a requirement of bitstream conformance that the following conditions apply:

- There shall be no j in the range of 0 to NumPocStCurrBefore – 1, inclusive, for which PocLtCurr[i] is equal to PocStCurrBefore[j].
- There shall be no j in the range of 0 to NumPocStCurrAfter – 1, inclusive, for which PocLtCurr[i] is equal to PocStCurrAfter[j].
- There shall be no j in the range of 0 to NumPocStFoll – 1, inclusive, for which PocLtCurr[i] is equal to PocStFoll[j].
- There shall be no j in the range of 0 to NumPocLtCurr – 1, inclusive, where j is not equal to i , for which PocLtCurr[i] is equal to PocLtCurr[j].

For each i in the range of 0 to NumPocLtFoll – 1, inclusive, when FollDeltaPocMsbPresentFlag[i] is equal to 1, it is a requirement of bitstream conformance that the following conditions apply:

- There shall be no j in the range of 0 to NumPocStCurrBefore – 1, inclusive, for which PocLtFoll[i] is equal to PocStCurrBefore[j].
- There shall be no j in the range of 0 to NumPocStCurrAfter – 1, inclusive, for which PocLtFoll[i] is equal to PocStCurrAfter[j].
- There shall be no j in the range of 0 to NumPocStFoll – 1, inclusive, for which PocLtFoll[i] is equal to PocStFoll[j].
- There shall be no j in the range of 0 to NumPocLtFoll – 1, inclusive, where j is not equal to i , for which PocLtFoll[i] is equal to PocLtFoll[j].
- There shall be no j in the range of 0 to NumPocLtCurr – 1, inclusive, for which PocLtFoll[i] is equal to PocLtCurr[j].

For each i in the range of 0 to NumPocLtCurr – 1, inclusive, when CurrDeltaPocMsbPresentFlag[i] is equal to 0, it is a requirement of bitstream conformance that the following conditions apply:

- There shall be no j in the range of 0 to $\text{NumPocStCurrBefore} - 1$, inclusive, for which $\text{PocLtCurr}[i]$ is equal to $(\text{PocStCurrBefore}[j] \& (\text{MaxPicOrderCntLsb} - 1))$.
- There shall be no j in the range of 0 to $\text{NumPocStCurrAfter} - 1$, inclusive, for which $\text{PocLtCurr}[i]$ is equal to $(\text{PocStCurrAfter}[j] \& (\text{MaxPicOrderCntLsb} - 1))$.
- There shall be no j in the range of 0 to $\text{NumPocStFoll} - 1$, inclusive, for which $\text{PocLtCurr}[i]$ is equal to $(\text{PocStFoll}[j] \& (\text{MaxPicOrderCntLsb} - 1))$.
- There shall be no j in the range of 0 to $\text{NumPocLtCurr} - 1$, inclusive, where j is not equal to i , for which $\text{PocLtCurr}[i]$ is equal to $(\text{PocLtCurr}[j] \& (\text{MaxPicOrderCntLsb} - 1))$.

For each i in the range of 0 to $\text{NumPocLtFoll} - 1$, inclusive, when $\text{FollDeltaPocMsbPresentFlag}[i]$ is equal to 0, it is a requirement of bitstream conformance that the following conditions apply:

- There shall be no j in the range of 0 to $\text{NumPocStCurrBefore} - 1$, inclusive, for which $\text{PocLtFoll}[i]$ is equal to $(\text{PocStCurrBefore}[j] \& (\text{MaxPicOrderCntLsb} - 1))$.
- There shall be no j in the range of 0 to $\text{NumPocStCurrAfter} - 1$, inclusive, for which $\text{PocLtFoll}[i]$ is equal to $(\text{PocStCurrAfter}[j] \& (\text{MaxPicOrderCntLsb} - 1))$.
- There shall be no j in the range of 0 to $\text{NumPocStFoll} - 1$, inclusive, for which $\text{PocLtFoll}[i]$ is equal to $(\text{PocStFoll}[j] \& (\text{MaxPicOrderCntLsb} - 1))$.
- There shall be no j in the range of 0 to $\text{NumPocLtFoll} - 1$, inclusive, where j is not equal to i , for which $\text{PocLtFoll}[i]$ is equal to $(\text{PocLtFoll}[j] \& (\text{MaxPicOrderCntLsb} - 1))$.
- There shall be no j in the range of 0 to $\text{NumPocLtCurr} - 1$, inclusive, for which $\text{PocLtFoll}[i]$ is equal to $(\text{PocLtCurr}[j] \& (\text{MaxPicOrderCntLsb} - 1))$.

The variable NumPicTotalCurr is derived as specified in clause 7.4.7.2. It is a requirement of bitstream conformance that the following applies to the value of NumPicTotalCurr :

- If the current picture is a BLA or CRA picture, the value of NumPicTotalCurr shall be equal to $\text{pps_curr_pic_ref_enabled_flag}$.
- Otherwise, when the current picture contains a P or B slice, the value of NumPicTotalCurr shall not be equal to 0.

The RPS of the current picture consists of five RPS lists; $\text{RefPicSetStCurrBefore}$, $\text{RefPicSetStCurrAfter}$, RefPicSetStFoll , RefPicSetLtCurr and RefPicSetLtFoll . $\text{RefPicSetStCurrBefore}$, $\text{RefPicSetStCurrAfter}$ and RefPicSetStFoll are collectively referred to as the short-term RPS. RefPicSetLtCurr and RefPicSetLtFoll are collectively referred to as the long-term RPS.

NOTE 3 – $\text{RefPicSetStCurrBefore}$, $\text{RefPicSetStCurrAfter}$ and RefPicSetLtCurr contain all reference pictures that may be used for inter prediction of the current picture and one or more pictures that follow the current picture in decoding order. RefPicSetStFoll and RefPicSetLtFoll consist of all reference pictures that are *not* used for inter prediction of the current picture but may be used in inter prediction for one or more pictures that follow the current picture in decoding order.

The derivation process for the RPS and picture marking are performed according to the following ordered steps:

1. The following applies:

```

for( i = 0; i < NumPocLtCurr; i++ )
    if( !CurrDeltaPocMsbPresentFlag[ i ] )
        if( there is a reference picture picX in the DPB with
            PicOrderCntVal & ( MaxPicOrderCntLsb - 1 )
                equal to PocLtCurr[ i ] and nuh_layer_id equal to currPicLayerId )
            RefPicSetLtCurr[ i ] = picX
        else
            RefPicSetLtCurr[ i ] = "no reference picture"
    else
        if( there is a reference picture picX in the DPB with PicOrderCntVal equal to PocLtCurr[ i ]
            and nuh_layer_id equal to currPicLayerId )
            RefPicSetLtCurr[ i ] = picX
        else
            RefPicSetLtCurr[ i ] = "no reference picture"

```

(8-6)

```

for( i = 0; i < NumPocLtFoll; i++ )
    if( !FollDeltaPocMsbPresentFlag[ i ] )
        if( there is a reference picture picX in the DPB with

```

```

PicOrderCntVal & ( MaxPicOrderCntLsb - 1 )
    equal to PocLtFoll[ i ] and nuh_layer_id equal to currPicLayerId )
    RefPicSetLtFoll[ i ] = picX
else
    RefPicSetLtFoll[ i ] = "no reference picture"
else
    if( there is a reference picture picX in the DPB with PicOrderCntVal equal to PocLtFoll[ i ]
        and nuh_layer_id equal to currPicLayerId )
        RefPicSetLtFoll[ i ] = picX
    else
        RefPicSetLtFoll[ i ] = "no reference picture"

```

2. All reference pictures that are included in RefPicSetLtCurr or RefPicSetLtFoll and have nuh_layer_id equal to currPicLayerId are marked as "used for long-term reference".

3. The following applies:

```

for( i = 0; i < NumPocStCurrBefore; i++ )
    if( there is a short-term reference picture picX in the DPB
        with PicOrderCntVal equal to PocStCurrBefore[ i ] and nuh_layer_id equal to
currPicLayerId )
        RefPicSetStCurrBefore[ i ] = picX
    else
        RefPicSetStCurrBefore[ i ] = "no reference picture"

```

```

for( i = 0; i < NumPocStCurrAfter; i++ )
    if( there is a short-term reference picture picX in the DPB
        with PicOrderCntVal equal to PocStCurrAfter[ i ] and nuh_layer_id equal to
currPicLayerId )
        RefPicSetStCurrAfter[ i ] = picX
    else
        RefPicSetStCurrAfter[ i ] = "no reference picture"

```

(8-7)

```

for( i = 0; i < NumPocStFoll; i++ )
    if( there is a short-term reference picture picX in the DPB
        with PicOrderCntVal equal to PocStFoll[ i ] and nuh_layer_id equal to currPicLayerId )
        RefPicSetStFoll[ i ] = picX
    else
        RefPicSetStFoll[ i ] = "no reference picture"

```

4. All reference pictures in the DPB that are not included in RefPicSetLtCurr, RefPicSetLtFoll, RefPicSetStCurrBefore, RefPicSetStCurrAfter, or RefPicSetStFoll and have nuh_layer_id equal to currPicLayerId are marked as "unused for reference".

NOTE 4 – There may be one or more entries in the RPS lists that are equal to "no reference picture" because the corresponding pictures are not present in the DPB. Entries in RefPicSetStFoll or RefPicSetLtFoll that are equal to "no reference picture" should be ignored. An unintentional picture loss should be inferred for each entry in RefPicSetStCurrBefore, RefPicSetStCurrAfter, or RefPicSetLtCurr that is equal to "no reference picture".

NOTE 5 – A picture cannot be included in more than one of the five RPS lists.

It is a requirement of bitstream conformance that the RPS is restricted as follows:

- There shall be no entry in RefPicSetStCurrBefore, RefPicSetStCurrAfter or RefPicSetLtCurr for which one or more of the following are true:
 - The entry is equal to "no reference picture".
 - The entry is an SLNR picture and has TemporalId equal to that of the current picture.
 - The entry is a picture that has TemporalId greater than that of the current picture.
- There shall be no entry in RefPicSetLtCurr or RefPicSetLtFoll for which the difference between the picture order count value of the current picture and the picture order count value of the entry is greater than or equal to 2^{24} .

- When the current picture is a temporal sub-layer access (TSA) picture, there shall be no picture included in the RPS with TemporalId greater than or equal to the TemporalId of the current picture.
- When the current picture is a step-wise temporal sub-layer access (STSA) picture, there shall be no picture included in RefPicSetStCurrBefore, RefPicSetStCurrAfter or RefPicSetLtCurr that has TemporalId equal to that of the current picture.
- When the current picture is a picture that follows, in decoding order, an STSA picture that has TemporalId equal to that of the current picture, there shall be no picture that has TemporalId equal to that of the current picture included in RefPicSetStCurrBefore, RefPicSetStCurrAfter or RefPicSetLtCurr that precedes the STSA picture in decoding order.
- When the current picture is a CRA picture, there shall be no picture included in the RPS that precedes, in output order or decoding order, any preceding IRAP picture in decoding order (when present).
- When the current picture is a trailing picture, there shall be no picture in RefPicSetStCurrBefore, RefPicSetStCurrAfter or RefPicSetLtCurr that was generated by the decoding process for generating unavailable reference pictures as specified in clause 8.3.3.
- When the current picture is a trailing picture, there shall be no picture in the RPS that precedes the associated IRAP picture in output order or decoding order.
- When the current picture is a RADL picture, there shall be no picture included in RefPicSetStCurrBefore, RefPicSetStCurrAfter or RefPicSetLtCurr that is any of the following:
 - A RASL picture
 - A picture that was generated by the decoding process for generating unavailable reference pictures as specified in clause 8.3.3
 - A picture that precedes the associated IRAP picture in decoding order
- When sps_temporal_id_nesting_flag is equal to 1, the following applies:
 - Let tIdA be the value of TemporalId of the current picture picA.
 - Any picture picB with TemporalId equal to tIdB that is less than or equal to tIdA shall not be included in RefPicSetStCurrBefore, RefPicSetStCurrAfter or RefPicSetLtCurr of picA when there exists a picture picC that has TemporalId less than tIdB, follows picB in decoding order, and precedes picA in decoding order.

8.3.3 Decoding process for generating unavailable reference pictures

8.3.3.1 General decoding process for generating unavailable reference pictures

This process is invoked once per coded picture when the current picture is a BLA picture or is a CRA picture with NoRasOutputFlag equal to 1.

NOTE – This process is primarily specified only for the specification of syntax constraints for RASL pictures. The entire specification of the decoding process for RASL pictures associated with an IRAP picture that has NoRasOutputFlag equal to 1 is included herein only for purposes of specifying constraints on the allowed syntax content of such RASL pictures. During the decoding process, any RASL pictures associated with an IRAP picture that has NoRasOutputFlag equal to 1 may be ignored, as these pictures are not specified for output and have no effect on the decoding process of any other pictures that are specified for output. However, in HRD operations as specified in Annex C, RASL access units may need to be taken into consideration in derivation of coded picture buffer (CPB) arrival and removal times.

When this process is invoked, the following applies:

- For each RefPicSetStFoll[i], with i in the range of 0 to NumPocStFoll – 1, inclusive, that is equal to "no reference picture", a picture is generated as specified in clause 8.3.3.2, and the following applies:
 - The value of PicOrderCntVal for the generated picture is set equal to PocStFoll[i].
 - The value of PicOutputFlag for the generated picture is set equal to 0.
 - The generated picture is marked as "used for short-term reference".
 - RefPicSetStFoll[i] is set to be the generated reference picture.
 - The value of nuh_layer_id for the generated picture is set equal to nuh_layer_id of the current picture.
- For each RefPicSetLtFoll[i], with i in the range of 0 to NumPocLtFoll – 1, inclusive, that is equal to "no reference picture", a picture is generated as specified in clause 8.3.3.2, and the following applies:
 - The value of PicOrderCntVal for the generated picture is set equal to PocLtFoll[i].

- The value of slice_pic_order_cnt_lsb for the generated picture is inferred to be equal to (PocLtFoll[i] & (MaxPicOrderCntLsb – 1)).
- The value of PicOutputFlag for the generated picture is set equal to 0.
- The generated picture is marked as "used for long-term reference".
- RefPicSetLtFoll[i] is set to be the generated reference picture.
- The value of nuh_layer_id for the generated picture is set equal to nuh_layer_id of the current picture.

8.3.3.2 Generation of one unavailable picture

When this process is invoked, an unavailable picture is generated as follows:

- The value of each element in the sample array S_L for the picture is set equal to $1 \ll (\text{BitDepth}_Y - 1)$.
- When ChromaArrayType is not equal to 0, the value of each element in the sample arrays S_{Cb} and S_{Cr} for the picture is set equal to $1 \ll (\text{BitDepth}_C - 1)$.
- The prediction mode CuPredMode[x][y] is set equal to MODE_INTRA for $x = 0..\text{pic_width_in_luma_samples} - 1$, $y = 0..\text{pic_height_in_luma_samples} - 1$.

8.3.4 Decoding process for reference picture lists construction

This process is invoked at the beginning of the decoding process for each P or B slice.

Reference pictures are addressed through reference indices as specified in clause 8.5.3.3.2. A reference index is an index into a reference picture list. When decoding a P slice, there is a single reference picture list RefPicList0. When decoding a B slice, there is a second independent reference picture list RefPicList1 in addition to RefPicList0.

At the beginning of the decoding process for each slice, the reference picture lists RefPicList0 and, for B slices, RefPicList1 are derived.

The variable NumRpsCurrTempList0 is set equal to $\text{Max}(\text{num_ref_idx_l0_active_minus1} + 1, \text{NumPicTotalCurr})$ and the list RefPicListTemp0 is constructed as follows:

If TwoVersionsOfCurrDecPicFlag is equal to 1, let the variable currPic be the current decoded picture before the invocation of the in-loop filter process; otherwise (TwoVersionsOfCurrDecPicFlag is equal to 0), let the variable currPic be the current decoded picture after the invocation of the in-loop filter process. The variable NumRpsCurrTempList0 is set equal to $\text{Max}(\text{num_ref_idx_l0_active_minus1} + 1, \text{NumPicTotalCurr})$ and the list RefPicListTemp0 is constructed as follows:

```

rIdx = 0
while( rIdx < NumRpsCurrTempList0 ) {
    for( i = 0; i < NumPocStCurrBefore && rIdx < NumRpsCurrTempList0; rIdx++, i++ )
        RefPicListTemp0[ rIdx ] = RefPicSetStCurrBefore[ i ]
    for( i = 0; i < NumPocStCurrAfter && rIdx < NumRpsCurrTempList0; rIdx++, i++ )           (8-8)
        RefPicListTemp0[ rIdx ] = RefPicSetStCurrAfter[ i ]
    for( i = 0; i < NumPocLtCurr && rIdx < NumRpsCurrTempList0; rIdx++, i++ )
        RefPicListTemp0[ rIdx ] = RefPicSetLtCurr[ i ]
    if( pps_curr_pic_ref_enabled_flag )
        RefPicListTemp0[ rIdx++ ] = currPic
}

```

The list RefPicList0 is constructed as follows:

```

for( rIdx = 0; rIdx <= num_ref_idx_l0_active_minus1; rIdx++ )
    RefPicList0[ rIdx ] = ref_pic_list_modification_flag_l0 ? RefPicListTemp0[ list_entry_l0[ rIdx ] ] :
                                                                RefPicListTemp0[ rIdx ]
if( pps_curr_pic_ref_enabled_flag && !ref_pic_list_modification_flag_l0 &&           (8-9)
    NumRpsCurrTempList0 > ( num_ref_idx_l0_active_minus1 + 1 ) )
    RefPicList0[ num_ref_idx_l0_active_minus1 ] = currPic

```

When the slice is a B slice, the variable NumRpsCurrTempList1 is set equal to $\text{Max}(\text{num_ref_idx_l1_active_minus1} + 1, \text{NumPicTotalCurr})$ and the list RefPicListTemp1 is constructed as follows:

```

rIdx = 0
while( rIdx < NumRpsCurrTempList1 ) {
    for( i = 0; i < NumPocStCurrAfter && rIdx < NumRpsCurrTempList1; rIdx++, i++ )
        RefPicListTemp1[ rIdx ] = RefPicSetStCurrAfter[ i ]
    for( i = 0; i < NumPocStCurrBefore && rIdx < NumRpsCurrTempList1; rIdx++, i++ )      (8-10)
        RefPicListTemp1[ rIdx ] = RefPicSetStCurrBefore[ i ]
    for( i = 0; i < NumPocLtCurr && rIdx < NumRpsCurrTempList1; rIdx++, i++ )
        RefPicListTemp1[ rIdx ] = RefPicSetLtCurr[ i ]
    if( pps_curr_pic_ref_enabled_flag )
        RefPicListTemp1[ rIdx++ ] = currPic
}

```

When the slice is a B slice, the list RefPicList1 is constructed as follows:

```

for( rIdx = 0; rIdx <= num_ref_idx_l1_active_minus1; rIdx++ )
    RefPicList1[ rIdx ] = ref_pic_list_modification_flag_l1 ? RefPicListTemp1[ list_entry_l1[ rIdx ] ] :
                                                                RefPicListTemp1[ rIdx ]
(8-11)

```

It is a requirement of bitstream conformance that when nuh_layer_id is equal to 0, nal_unit_type has a value in the range of BLA_W_LP to RSV_IRAP_VCL23, inclusive (i.e. the picture is an IRAP picture), pps_curr_pic_ref_enabled_flag is equal to 1, and slice_type is not equal to 2, RefPicList0 and RefPicList1 shall not contain entries that refer to a picture other than the current picture.

8.3.5 Decoding process for collocated picture and no backward prediction flag

This process is invoked at the beginning of the decoding process for each P or B slice, after decoding of the slice header as well as the invocation of the decoding process for reference picture set as specified in clause 8.3.2 and the invocation of the decoding process for reference picture list construction for the slice as specified in clause 8.3.4, but prior to the decoding of any coding unit.

When slice_temporal_mvp_enabled_flag is equal to 1, the variable ColPic is derived as follows:

- If slice_type is equal to B and collocated_from_l0_flag is equal to 0, ColPic is set equal to RefPicList1[collocated_ref_idx].
- Otherwise (slice_type is equal to B and collocated_from_l0_flag is equal to 1, or slice_type is equal to P), ColPic is set equal to RefPicList0[collocated_ref_idx].

The variable NoBackwardPredFlag is derived as follows:

- If DiffPicOrderCnt(aPic, CurrPic) is less than or equal to 0 for each picture aPic in RefPicList0 or RefPicList1 of the current slice, NoBackwardPredFlag is set equal to 1.
- Otherwise, NoBackwardPredFlag is set equal to 0.

8.4 Decoding process for coding units coded in intra prediction mode

8.4.1 General decoding process for coding units coded in intra prediction mode

Inputs to this process are:

- a luma location (xCb, yCb) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a variable log2CbSize specifying the size of the current luma coding block.

Output of this process is a modified reconstructed picture before deblocking filtering.

The derivation process for quantization parameters as specified in clause 8.6.1 is invoked with the luma location (xCb, yCb) as input.

A variable nCbS is set equal to $1 \ll \log_2 \text{CbSize}$.

When residual_adaptive_colour_transform_enabled_flag is equal to 1, the residual sample arrays resSamplesL, resSamplesCb, and resSamplesCr store the residual samples of the current coding unit.

Depending on the values of `pcm_flag[xCb][yCb]`, `palette_mode_flag[xCb][yCb]`, and `IntraSplitFlag`, the decoding process for luma samples is specified as follows:

- If `pcm_flag[xCb][yCb]` is equal to 1, the reconstructed picture is modified as follows:

$$S_L[xCb + i][yCb + j] = \text{pcm_sample_luma}[(nCbS * j) + i] \ll (\text{BitDepth}_Y - \text{PcmBitDepth}_Y), \text{ with } i, j = 0..nCbS - 1 \quad (8-12)$$

- Otherwise (`pcm_flag[xCb][yCb]` is equal to 0), if `palette_mode_flag[xCb][yCb]` is equal to 1, the following ordered steps apply:

1. The decoding process for palette intra blocks as specified in clause 8.4.4.2.7 is invoked with the luma location (`xCb`, `yCb`), the variable `cIdx` set equal to 0, and `nCbSX` and `nCbSY` both set equal to `nCbS` as inputs, and the output is an `nCbS` x `nCbS` array of reconstructed palette sample values, `recSamples[x][y]`, `x`, `y` = 0..`nCbS` – 1.
2. The reconstructed picture is modified as follows for `x`, `y` = 0..`nCbS` – 1 and `y` = 0..`nCbS` – 1:

- If `palette_transpose_flag` is equal to 1, the following applies:

$$S_L[xCb + x][yCb + y] = \text{recSamples}[y][x] \quad (8-13)$$

- Otherwise (`palette_transpose_flag` is equal to 0), the following applies:

$$S_L[xCb + x][yCb + y] = \text{recSamples}[x][y] \quad (8-14)$$

- Otherwise (`pcm_flag[xCb][yCb]` is equal to 0, `palette_mode_flag[xCb][yCb]` is equal to 0), if `IntraSplitFlag` is equal to 0, the following ordered steps apply:

1. The derivation process for the intra prediction mode as specified in clause 8.4.2 is invoked with the luma location (`xCb`, `yCb`) as input.
2. If `residual_adaptive_colour_transform_enabled_flag` is equal to 1, the following applies:
 - The general decoding process for intra blocks as specified in clause 8.4.4.1 is invoked with the luma location (`xCb`, `yCb`), the variable `log2TrafoSize` set equal to `log2CbSize`, the variable `trafoDepth` set equal to 0, the variable `predModeIntra` set equal to `IntraPredModeY[xCb][yCb]`, the variable `cIdx` set equal to 0 and variable `controlParaAct` set equal to 1 as inputs, and the output is a modified residual sample array `resSamplesL`.
 - The general decoding process for intra blocks as specified in clause 8.4.4.1 is invoked with the chroma location (`xCb`, `yCb`), the variable `log2TrafoSize` set equal to `log2CbSize`, the variable `trafoDepth` set equal to 0, the variable `predModeIntra` set equal to `IntraPredModeC`, the variable `cIdx` set equal to 1 and variable `controlParaAct` set equal to 1 as inputs, and the output is a modified residual sample array `resSamplesCb`.
 - The general decoding process for intra blocks as specified in clause 8.4.4.1 is invoked with the chroma location (`xCb`, `yCb`), the variable `log2TrafoSize` set equal to `log2CbSize`, the variable `trafoDepth` set equal to 0, the variable `predModeIntra` set equal to `IntraPredModeC`, the variable `cIdx` set equal to 2 and variable `controlParaAct` set equal to 1 as inputs, and the output is a modified residual sample array `resSamplesCr`.
 - The residual modification process for blocks using adaptive colour transform as specified in clause 8.6.8 is invoked with location (`xCb`, `yCb`), the variable `log2TrafoSize` set equal to `log2CbSize`, the variable `trafoDepth` set equal to 0, the variable `resSampleArrayL` set equal to `resSamplesL`, the variable `resSampleArrayCb` set equal to `resSamplesCb` and the variable `resSampleArrayCr` set equal to `resSamplesCr` as inputs, and the outputs are modified versions of `resSampleL`, `resSampleCb` and `resSampleCr`.
3. The general decoding process for intra blocks as specified in clause 8.4.4.1 is invoked with the luma location (`xCb`, `yCb`), the variable `log2TrafoSize` set equal to `log2CbSize`, the variable `trafoDepth` set equal to 0, the variable `predModeIntra` set equal to `IntraPredModeY[xCb][yCb]`, the variable `cIdx` set equal to 0, the variable `controlParaAct` set equal to (`residual_adaptive_colour_transform_enabled_flag ? 2 : 0`), and the array `resSamplesL` when `controlParaAct` is equal to 2 as inputs, and the output is a modified reconstructed picture before deblocking filtering.
- Otherwise (`pcm_flag[xCb][yCb]` is equal to 0, `palette_mode_flag[xCb][yCb]` is equal to 0, and `IntraSplitFlag` is equal to 1), for the variable `blkIdx` proceeding over the values 0..3, the following ordered steps apply:
 1. The variable `xPb` is set equal to `xCb + (nCbS >> 1) * (blkIdx % 2)`.

2. The variable y_{Pb} is set equal to $y_{Cb} + (n_{CbS} \gg 1) * (blkIdx / 2)$.
3. The derivation process for the intra prediction mode as specified in clause 8.4.2 is invoked with the luma location (x_{Pb}, y_{Pb}) as input.
4. If `residual_adaptive_colour_transform_enabled_flag` is equal to 1, the following applies:
 - The general decoding process for intra blocks as specified in clause 8.4.4.1 is invoked with the luma location (x_{Pb}, y_{Pb}) , the variable $\log_2TrafoSize$ set equal to $\log_2CbSize - 1$, the variable $trafoDepth$ set equal to 1, the variable $predModeIntra$ set equal to $IntraPredModeY[x_{Pb}][y_{Pb}]$, the variable $cIdx$ set equal to 0 and variable $controlParaAct$ equal to 1 as inputs, and the output is a modified residual sample array $resSamplesL$.
 - The general decoding process for intra blocks as specified in clause 8.4.4.1 is invoked with the chroma location (x_{Pb}, y_{Pb}) , the variable $\log_2TrafoSize$ set equal to $\log_2CbSize - 1$, the variable $trafoDepth$ set equal to 1, the variable $predModeIntra$ set equal to $IntraPredModeC$, the variable $cIdx$ set equal to 1 and variable $controlParaAct$ equal to 1 as inputs, and the output is a modified residual sample array $resSamplesCb$.
 - The general decoding process for intra blocks as specified in clause 8.4.4.1 is invoked with the chroma location (x_{Pb}, y_{Pb}) , the variable $\log_2TrafoSize$ set equal to $\log_2CbSize - 1$, the variable $trafoDepth$ set equal to 1, the variable $predModeIntra$ set equal to $IntraPredModeC$, the variable $cIdx$ set equal to 2 and variable $controlParaAct$ set equal to 1 as inputs, and the output is a modified residual sample array $resSamplesCr$.
 - The residual modification process for blocks using adaptive colour transform as specified in clause 8.6.8 is invoked with location (x_{Cb}, y_{Cb}) , the variable $\log_2TrafoSize$ set equal to $\log_2CbSize - 1$, the variable $trafoDepth$ set equal to 1, the variable $resSampleArrayL$ set equal to $resSamplesL$, the variable $resSampleArrayCb$ set equal to $resSamplesCb$ and the variable $resSampleArrayCr$ set equal to $resSamplesCr$ as inputs, and the outputs are modified versions of $resSampleL$, $resSampleCb$ and $resSampleCr$.
5. The general decoding process for intra blocks as specified in clause 8.4.4.1 is invoked with the luma location (x_{Pb}, y_{Pb}) , the variable $\log_2TrafoSize$ set equal to $\log_2CbSize - 1$, the variable $trafoDepth$ set equal to 1, the variable $predModeIntra$ set equal to $IntraPredModeY[x_{Pb}][y_{Pb}]$, the variable $cIdx$ set equal to 0, the variable $controlParaAct$ set equal to $(residual_adaptive_colour_transform_enabled_flag ? 2 : 0)$, and the array $resSamplesL$ when $controlParaAct$ is equal to 2 as inputs, and the output is a modified reconstructed picture before deblocking filtering.

When `ChromaArrayType` is not equal to 0, the following applies.

The variable $\log_2CbSizeC$ is set equal to $\log_2CbSize - (ChromaArrayType == 3 ? 0 : 1)$.

Depending on the values of `pcm_flag[xCb][yCb]` and `IntraSplitFlag`, the decoding process for chroma samples is specified as follows:

- If `pcm_flag[xCb][yCb]` is equal to 1, the reconstructed picture is modified as follows:

$$S_{Cb}[xCb / SubWidthC + i][yCb / SubHeightC + j] = \text{pcm_sample_chroma}[(n_{CbS} / SubWidthC * j) + i] \ll (BitDepth_C - PcmBitDepth_C),$$

with $i = 0..n_{CbS} / SubWidthC - 1$ and $j = 0..n_{CbS} / SubHeightC - 1$ (8-15)

$$S_{Cr}[xCb / SubWidthC + i][yCb / SubHeightC + j] = \text{pcm_sample_chroma}[(n_{CbS} / SubWidthC * (j + n_{CbS} / SubHeightC)) + i] \ll (BitDepth_C - PcmBitDepth_C),$$

with $i = 0..n_{CbS} / SubWidthC - 1$ and $j = 0..n_{CbS} / SubHeightC - 1$ (8-16)

- Otherwise (`pcm_flag[xCb][yCb]` is equal to 0), if `palette_mode_flag[xCb][yCb]` is equal to 1 the following ordered steps apply:

1. n_{CbSX} is set as follows:

- If `palette_transpose_flag` is equal to 1, n_{CbSX} is set equal to $(n_{CbS} / SubHeightC)$, n_{CbY} is set equal to $(n_{CbS} / SubWidthC)$.
- Otherwise (`palette_transpose_flag` is equal to 0) n_{CbSX} is set equal to $(n_{CbS} / SubWidthC)$, n_{CbY} is set equal to $(n_{CbS} / SubHeightC)$.

2. The decoding process for palette intra blocks as specified in clause 8.4.4.2.7 is invoked with the chroma location (x_{Cb}, y_{Cb}) , the variable $cIdx$ set equal to 1, n_{CbSX} , and n_{CbSY} as inputs, and the output is an $(n_{CbS} / SubWidthC) \times (n_{CbS} / SubHeightC)$ array of reconstructed palette sample values, $recSamples[x][y]$, $x = 0 \dots n_{CbS} / SubWidthC - 1$, $y = 0..n_{CbS} / SubHeightC - 1$, when `palette_transpose_flag` is equal to 0, or an

$(nCbS / SubHeightC) \times (nCbS / SubWidthC)$ array of reconstructed palette sample values, $recSamples[x][y]$, $x = 0 \dots nCbS / SubWidthC - 1$, $y = 0 \dots nCbS / SubHeightC - 1$ when `palette_transpose_flag` is equal to 1.

3. The reconstructed picture is modified as follows:

- If `palette_transpose_flag` is equal to 1, the following applies:

$$SCb[xCb / SubWidthC + x][yCb / SubHeightC + y] = recSamples[y][x],$$

with $x = 0 \dots nCbS / SubWidthC - 1$ and $y = 0 \dots nCbS / SubHeightC - 1$ (8-17)

- Otherwise (`palette_transpose_flag` is equal to 0), the following applies:

$$SCb[xCb / SubWidthC + x][yCb / SubHeightC + y] = recSamples[x][y],$$

with $x = 0 \dots nCbS / SubWidthC - 1$ and $y = 0 \dots nCbS / SubHeightC - 1$ (8-18)

4. The decoding process for palette intra blocks as specified in clause 8.4.4.2.7 is invoked with the chroma location (xCb, yCb) , the variable `cIdx` set equal to 2, `nCbSX` set equal to $nCbS / SubWidthC$, and `nCbSY` set equal to $nCbS / SubHeightC$ as inputs, and the output is an $(nCbS / SubWidthC) \times (nCbS / SubHeightC)$ array of reconstructed palette sample values, $recSamples[x][y]$, $x = 0 \dots nCbS / SubWidthC - 1$, $y = 0 \dots nCbS / SubHeightC - 1$, when `palette_transpose_flag` is equal to 0, or an $(nCbS / SubHeightC) \times (nCbS / SubWidthC)$ array of reconstructed palette sample values, $recSamples[x][y]$, $x = 0 \dots nCbS / SubHeightC - 1$, $y = 0 \dots nCbS / SubWidthC - 1$, when `palette_transpose_flag` is equal to 1.

5. The reconstructed picture is modified as follows:

- If `palette_transpose_flag` is equal to 1, the following applies:

$$SCr[xCb / SubWidthC + x][yCb / SubHeightC + y] = recSamples[y][x],$$

with $x = 0 \dots nCbS / SubWidthC - 1$ and $y = 0 \dots nCbS / SubHeightC - 1$ (8-19)

- Otherwise (`palette_transpose_flag` is equal to 0), the following applies:

$$SCr[xCb / SubWidthC + x][yCb / SubHeightC + y] = recSamples[x][y],$$

with $x = 0 \dots nCbS / SubWidthC - 1$ and $y = 0 \dots nCbS / SubHeightC - 1$ (8-20)

- Otherwise (`pcm_flag[xCb][yCb]` is equal to 0 and `palette_mode_flag[xCb][yCb]` is equal to 0), if `IntraSplitFlag` is equal to 0 or `ChromaArrayType` is not equal to 3, the following ordered steps apply:

1. The derivation process for the chroma intra prediction mode as specified in clause 8.4.3 is invoked with the luma location (xCb, yCb) as input, and the output is the variable `IntraPredModeC`.
2. The general decoding process for intra blocks as specified in clause 8.4.4.1 is invoked with the chroma location $(xCb / SubWidthC, yCb / SubHeightC)$, the variable `log2TrafoSize` set equal to `log2CbSizeC`, the variable `trafoDepth` set equal to 0, the variable `predModeIntra` set equal to `IntraPredModeC`, the variable `cIdx` set equal to 1, the variable `controlParaAct` set equal to $(residual_adaptive_colour_transform_enabled_flag ? 2 : 0)$, and the array `resSamplesCb` when `controlParaAct` is equal to 2 as inputs, and the output is a modified reconstructed picture before deblocking filtering.
3. The general decoding process for intra blocks as specified in clause 8.4.4.1 is invoked with the chroma location $(xCb / SubWidthC, yCb / SubHeightC)$, the variable `log2TrafoSize` set equal to `log2CbSizeC`, the variable `trafoDepth` set equal to 0, the variable `predModeIntra` set equal to `IntraPredModeC`, the variable `cIdx` set equal to 2, the variable `controlParaAct` set equal to $(residual_adaptive_colour_transform_enabled_flag ? 2 : 0)$, and the array `resSamplesCr` when `controlParaAct` is equal to 2 as inputs, and the output is a modified reconstructed picture before deblocking filtering.

- Otherwise (`pcm_flag[xCb][yCb]` is equal to 0, `palette_mode_flag[xCb][yCb]` is equal to 0, `IntraSplitFlag` is equal to 1 and `ChromaArrayType` is equal to 3), for the variable `blkIdx` proceeding over the values 0..3, the following ordered steps apply:

1. The variable `xPb` is set equal to $xCb + (nCbS \gg 1) * (blkIdx \% 2)$.
2. The variable `yPb` is set equal to $yCb + (nCbS \gg 1) * (blkIdx / 2)$.
3. The derivation process for the chroma intra prediction mode as specified in clause 8.4.3 is invoked with the luma location (xPb, yPb) as input, and the output is the variable `IntraPredModeC`.

4. The general decoding process for intra blocks as specified in clause 8.4.4.1 is invoked with the chroma location (xPb, yPb), the variable log2TrafoSize set equal to log2CbSizeC – 1, the variable trafoDepth set equal to 1, the variable predModeIntra set equal to IntraPredModeC, the variable cIdx set equal to 1, the variable controlParaAct set equal to (residual_adaptive_colour_transform_enabled_flag ? 2 : 0), and the array resSamplesCb when controlParaAct is equal to 2 as inputs, and the output is a modified reconstructed picture before deblocking filtering.
5. The general decoding process for intra blocks as specified in clause 8.4.4.1 is invoked with the chroma location (xPb, yPb), the variable log2TrafoSize set equal to log2CbSizeC – 1, the variable trafoDepth set equal to 1, the variable predModeIntra set equal to IntraPredModeC, the variable cIdx set equal to 2, the variable controlParaAct set equal to (residual_adaptive_colour_transform_enabled_flag ? 2 : 0), and the array resSamplesCr when controlParaAct is equal to 2 as inputs, and the output is a modified reconstructed picture before deblocking filtering.

8.4.2 Derivation process for luma intra prediction mode

Input to this process is a luma location (xPb, yPb) specifying the top-left sample of the current luma prediction block relative to the top-left luma sample of the current picture.

In this process, the luma intra prediction mode IntraPredModeY[xPb][yPb] is derived.

Table 8-1 specifies the value for the intra prediction mode and the associated names.

Table 8-1 – Specification of intra prediction mode and associated names

Intra prediction mode	Associated name
0	INTRA_PLANAR
1	INTRA_DC
2..34	INTRA_ANGULAR2..INTRA_ANGULAR34

IntraPredModeY[xPb][yPb] labelled 0..34 represents directions of predictions as illustrated in Figure 8-1.

Figure 8-1 – Intra prediction mode directions (informative)

IntraPredModeY[xPb][yPb] is derived by the following ordered steps:

1. The neighbouring locations (xNbA, yNbA) and (xNbB, yNbB) are set equal to (xPb – 1, yPb) and (xPb, yPb – 1), respectively.
2. For X being replaced by either A or B, the variables candIntraPredModeX are derived as follows:
 - The availability derivation process for a block in z-scan order as specified in clause 6.4.1 is invoked with the location (xCurr, yCurr) set equal to (xPb, yPb) and the neighbouring location (xNbY, yNbY) set equal to (xNbX, yNbX) as inputs, and the output is assigned to availableX.
 - The candidate intra prediction mode candIntraPredModeX is derived as follows:
 - If availableX is equal to FALSE, candIntraPredModeX is set equal to INTRA_DC.
 - Otherwise, if CuPredMode[xNbX][yNbX] is not equal to MODE_INTRA or pcm_flag[xNbX][yNbX] is equal to 1, candIntraPredModeX is set equal to INTRA_DC,
 - Otherwise, if X is equal to B and yPb – 1 is less than ((yPb >> CtbLog2SizeY) << CtbLog2SizeY), candIntraPredModeB is set equal to INTRA_DC.
 - Otherwise, candIntraPredModeX is set equal to IntraPredModeY[xNbX][yNbX].
3. The candModeList[x] with x = 0..2 is derived as follows:
 - If candIntraPredModeB is equal to candIntraPredModeA, the following applies:
 - If candIntraPredModeA is less than 2 (i.e., equal to INTRA_PLANAR or INTRA_DC), candModeList[x] with x = 0..2 is derived as follows:

$$\text{candModeList}[0] = \text{INTRA_PLANAR} \quad (8-21)$$

$$\text{candModeList}[1] = \text{INTRA_DC} \quad (8-22)$$

$$\text{candModeList}[2] = \text{INTRA_ANGULAR26} \quad (8-23)$$
 - Otherwise, candModeList[x] with x = 0..2 is derived as follows:

$$\text{candModeList}[0] = \text{candIntraPredModeA} \quad (8-24)$$

$$\text{candModeList}[1] = 2 + ((\text{candIntraPredModeA} + 29) \% 32) \quad (8-25)$$

$$\text{candModeList}[2] = 2 + ((\text{candIntraPredModeA} - 2 + 1) \% 32) \quad (8-26)$$
 - Otherwise (candIntraPredModeB is not equal to candIntraPredModeA), the following applies:
 - candModeList[0] and candModeList[1] are derived as follows:

$$\text{candModeList}[0] = \text{candIntraPredModeA} \quad (8-27)$$

$$\text{candModeList}[1] = \text{candIntraPredModeB} \quad (8-28)$$
 - If neither of candModeList[0] and candModeList[1] is equal to INTRA_PLANAR, candModeList[2] is set equal to INTRA_PLANAR,
 - Otherwise, if neither of candModeList[0] and candModeList[1] is equal to INTRA_DC, candModeList[2] is set equal to INTRA_DC,
 - Otherwise, candModeList[2] is set equal to INTRA_ANGULAR26.
4. IntraPredModeY[xPb][yPb] is derived by applying the following procedure:
 - If prev_intra_luma_pred_flag[xPb][yPb] is equal to 1, the IntraPredModeY[xPb][yPb] is set equal to candModeList[mpm_idx[xPb][yPb]].
 - Otherwise, IntraPredModeY[xPb][yPb] is derived by applying the following ordered steps:
 - 1) The array candModeList[x], x = 0..2 is modified as the following ordered steps:
 - i. When candModeList[0] is greater than candModeList[1], both values are swapped as follows:

$$(\text{candModeList}[0], \text{candModeList}[1]) = \text{Swap}(\text{candModeList}[0], \text{candModeList}[1]) \quad (8-29)$$

- ii. When $\text{candModeList}[0]$ is greater than $\text{candModeList}[2]$, both values are swapped as follows:

$$(\text{candModeList}[0], \text{candModeList}[2]) = \text{Swap}(\text{candModeList}[0], \text{candModeList}[2]) \quad (8-30)$$

- iii. When $\text{candModeList}[1]$ is greater than $\text{candModeList}[2]$, both values are swapped as follows:

$$(\text{candModeList}[1], \text{candModeList}[2]) = \text{Swap}(\text{candModeList}[1], \text{candModeList}[2]) \quad (8-31)$$

2) $\text{IntraPredModeY}[\text{xPb}][\text{yPb}]$ is derived by the following ordered steps:

- $\text{IntraPredModeY}[\text{xPb}][\text{yPb}]$ is set equal to $\text{rem_intra_luma_pred_mode}[\text{xPb}][\text{yPb}]$.
- For i equal to 0 to 2, inclusive, when $\text{IntraPredModeY}[\text{xPb}][\text{yPb}]$ is greater than or equal to $\text{candModeList}[i]$, the value of $\text{IntraPredModeY}[\text{xPb}][\text{yPb}]$ is incremented by one.

8.4.3 Derivation process for chroma intra prediction mode

This process is only invoked when ChromaArrayType is not equal to 0.

Input to this process is a luma location (xPb , yPb) specifying the top-left sample of the current chroma prediction block relative to the top-left luma sample of the current picture.

Output of this process is the variable IntraPredModeC .

The variable modeIdx is derived using $\text{intra_chroma_pred_mode}[\text{xPb}][\text{yPb}]$ and $\text{IntraPredModeY}[\text{xPb}][\text{yPb}]$ as specified in Table 8-2.

The chroma intra prediction mode IntraPredModeC is derived as follows:

- If ChromaArrayType is equal to 2, IntraPredModeC is set using modeIdx as specified in Table 8-3.
- Otherwise, IntraPredModeC is set equal to modeIdx .

Table 8-2 – Specification of modeIdx

$\text{intra_chroma_pred_mode}[\text{xPb}][\text{yPb}]$	$\text{IntraPredModeY}[\text{xPb}][\text{yPb}]$				
	0	26	10	1	$X (0 \leq X \leq 34)$
0	34	0	0	0	0
1	26	34	26	26	26
2	10	10	34	10	10
3	1	1	1	34	1
4	0	26	10	1	X

Table 8-3 – Specification of IntraPredModeC when ChromaArrayType is equal to 2

modeIdx	X <= 2		3	4	5	6	7	8	9	10	11	12	13	14	15	16	17

8.4.4 Decoding process for intra blocks

8.4.4.1 General decoding process for intra blocks

Inputs to this process are:

- a sample location ($xTb0, yTb0$) specifying the top-left sample of the current transform block relative to the top-left sample of the current picture,
- a variable $\log2TrafoSize$ specifying the size of the current transform block,
- a variable $trafoDepth$ specifying the hierarchy depth of the current block relative to the coding unit,
- a variable $predModeIntra$ specifying the intra prediction mode,
- a variable $cIdx$ specifying the colour component of the current block,
- a variable $controlParaAct$ specifying the applicable processes,
- when $controlParaAct$ is equal to 2, a residual sample array $resSamplesRec$ specifying the reconstructed residual samples for the current colour component of the current coding block.

Output of this process is a modified reconstructed picture before deblocking filtering when $controlParaAct$ is not equal to 1, or a modified residual sample array $resSampleArray$ for the current colour component of the current coding block when $controlParaAct$ is equal to 1.

The luma sample location ($xTbY, yTbY$) specifying the top-left sample of the current luma transform block relative to the top-left luma sample of the current picture is derived as follows:

$$(xTbY, yTbY) = (cIdx == 0) ? (xTb0, yTb0) : (xTb0 * SubWidthC, yTb0 * SubHeightC) \quad (8-32)$$

The variable $splitFlag$ is derived as follows:

- If $cIdx$ is equal to 0, $splitFlag$ is set equal to $split_transform_flag[xTbY][yTbY][trafoDepth]$.
- Otherwise, if all of the following conditions are true, $splitFlag$ is set equal to 1.
 - $cIdx$ is greater than 0
 - $split_transform_flag[xTbY][yTbY][trafoDepth]$ is equal to 1
 - $\log2TrafoSize$ is greater than 2
- Otherwise, $splitFlag$ is set equal to 0.

Depending on the value of $splitFlag$, the following applies:

- If $splitFlag$ is equal to 1, the following ordered steps apply:
 1. The variables $xTb1$ and $yTb1$ are derived as follows:
 - If $cIdx$ is equal to 0 or $ChromaArrayType$ is not equal to 2, the following applies:
 - The variable $xTb1$ is set equal to $xTb0 + (1 \ll (\log2TrafoSize - 1))$.
 - The variable $yTb1$ is set equal to $yTb0 + (1 \ll (\log2TrafoSize - 1))$.
 - Otherwise ($ChromaArrayType$ is equal to 2 and $cIdx$ is greater than 0), the following applies:
 - The variable $xTb1$ is set equal to $xTb0 + (1 \ll (\log2TrafoSize - 1))$.
 - The variable $yTb1$ is set equal to $yTb0 + (2 \ll (\log2TrafoSize - 1))$.
 2. The general decoding process for intra blocks as specified in this clause is invoked with the location ($xTb0, yTb0$), the variable $\log2TrafoSize$ set equal to $\log2TrafoSize - 1$, the variable $trafoDepth$ set equal to $trafoDepth + 1$, the intra prediction mode $predModeIntra$, the variable $cIdx$, the variable $controlParaAct$, and the array $resSamplesRec$ when $controlParaAct$ is equal to 2 as inputs and the output is a modified reconstructed picture before deblocking filtering when $controlParaAct$ is not equal to 1 or a modified residual sample array $resSampleArray$ when $controlParaAct$ is equal to 1.
 3. The general decoding process for intra blocks as specified in this clause is invoked with the location ($xTb1, yTb0$), the variable $\log2TrafoSize$ set equal to $\log2TrafoSize - 1$, the variable $trafoDepth$ set equal to $trafoDepth + 1$, the intra prediction mode $predModeIntra$, the variable $cIdx$, the variable $controlParaAct$, and the array $resSamplesRec$ when $controlParaAct$ is equal to 2 as inputs, and the output is a modified reconstructed

picture before deblocking filtering when controlParaAct is not equal to 1 or a modified residual sample array resSampleArray when controlParaAct is equal to 1.

4. The general decoding process for intra blocks as specified in this clause is invoked with the location (xTb0, yTb1), the variable log2TrafoSize set equal to log2TrafoSize – 1, the variable trafoDepth set equal to trafoDepth + 1, the intra prediction mode predModeIntra, the variable cIdx, the variable controlParaAct, and the array resSamplesRec when controlParaAct is equal to 2 as inputs, and the output is a modified reconstructed picture before deblocking filtering when controlParaAct is not equal to 1 or a modified residual sample array resSampleArray when controlParaAct is equal to 1.
5. The general decoding process for intra blocks as specified in this clause is invoked with the location (xTb1, yTb1), the variable log2TrafoSize set equal to log2TrafoSize – 1, the variable trafoDepth set equal to trafoDepth + 1, the intra prediction mode predModeIntra, the variable cIdx, the variable controlParaAct, and the array resSamplesRec when controlParaAct is equal to 2 as inputs, and the output is a modified reconstructed picture before deblocking filtering when controlParaAct is not equal to 1 or a modified residual sample array resSampleArray when controlParaAct is equal to 1.
- Otherwise (splitFlag is equal to 0), for the variable blkIdx proceeding over the values 0..(cIdx > 0 && ChromaArrayType == 2 ? 1 : 0), the following ordered steps apply:
 1. The variable nTbS is set equal to $1 \ll \log_2 \text{TrafoSize}$.
 2. The variable yTbOffset is set equal to blkIdx * nTbS.
 3. The variable yTbOffsetY is set equal to yTbOffset * SubHeightC.
 4. When controlParaAct is not equal to 2, the variable residualDpcm is derived as follows:
 - If all of the following conditions are true, residualDpcm is set equal to 1.
 - implicit_rdpem_enabled_flag is equal to 1.
 - either transform_skip_flag[xTbY][yTbY + yTbOffsetY][cIdx] is equal to 1, or cu_transquant_bypass_flag is equal to 1.
 - either predModeIntra is equal to 10, or predModeIntra is equal to 26.
 - Otherwise, residualDpcm is set equal to 0.
 5. When controlParaAct is not equal to 1, the general intra sample prediction process as specified in clause 8.4.4.2.1 is invoked with the transform block location (xTb0, yTb0 + yTbOffset), the intra prediction mode predModeIntra, the transform block size nTbS and the variable cIdx as inputs, and the output is an (nTbS)x(nTbS) array predSamples.
 6. When controlParaAct is not equal to 2, the scaling and transformation process as specified in clause 8.6.2 is invoked with the luma location (xTbY, yTbY + yTbOffsetY), the variable trafoDepth, the variable cIdx and the transform size trafoSize set equal to nTbS as inputs, and the output is an (nTbS)x(nTbS) array resSamples.
 7. When controlParaAct is not equal to 2 and residualDpcm is equal to 1, the directional residual modification process for blocks using a transform bypass as specified in clause 8.6.5 is invoked with the variable mDir set equal to predModeIntra / 26, the variable nTbS and the (nTbS)x(nTbS) array r set equal to the array resSamples as inputs, and the output is a modified (nTbS)x(nTbS) array resSamples.
 8. When controlParaAct is not equal to 2 and cross_component_prediction_enabled_flag is equal to 1, ChromaArrayType is equal to 3, and cIdx is not equal to 0, the residual modification process for transform blocks using cross-component prediction as specified in clause 8.6.6 is invoked with the current luma transform block location (xTbY, yTbY), the variable nTbS, the variable cIdx, the (nTbS)x(nTbS) array r_Y set equal to the corresponding luma residual sample array resSamples of the current transform block and the (nTbS)x(nTbS) array r set equal to the array resSamples as inputs, and the output is a modified (nTbS)x(nTbS) array resSamples.
 9. When controlParaAct is not equal to 0, the following applies:
 - The variable nCbS specifying the size of the current coding block is derived by setting nCbS equal to $1 \ll (\log_2 \text{TrafoSize} + \text{trafDepth})$.
 - The sample location (xTbInCb, yTbInCb) specifying the top-left sample of the current transform block relative to the top-left sample of the current coding block is derived by setting xTbInCb equal to xTb0 & (nCbS – 1) and setting yTbInCb equal to yTb0 & (nCbS – 1).
 10. When controlParaAct is equal to 2, the (nTbS)x(nTbS) array resSamples is derived by setting resSamples[x][y] equal to resSamplesRec[x + xTbInCb][y + yTbInCb], for x and y in the range of 0 to nTbS – 1, inclusive.

11. The following applies:

- If controlParaAct is equal to 1, the residual array resSamplesArray is modified by setting resSamplesArray[x + xTbInCb][y + yTbInCb] equal to resSamples[x][y], for x and y in the range of 0 to nTbS – 1, inclusive.
- Otherwise (controlParaAct is not equal to 1), the picture construction process prior to in-loop filtering for a colour component as specified in clause 8.6.7 is invoked with the transform block location (xTb0, yTb0 + yTbOffset), the variables nCurrSw and nCurrSh both set equal to nTbS, the variable cIdx, the (nTbS)x(nTbS) array predSamples and the (nTbS)x(nTbS) array resSamples as inputs.

8.4.4.2 Intra sample prediction

8.4.4.2.1 General intra sample prediction

Inputs to this process are:

- a sample location (xTbCmp, yTbCmp) specifying the top-left sample of the current transform block relative to the top-left sample of the current picture,
- a variable predModeIntra specifying the intra prediction mode,
- a variable nTbS specifying the transform block size,
- a variable cIdx specifying the colour component of the current block.

Outputs of this process are the predicted samples predSamples[x][y], with x, y = 0..nTbS – 1.

The nTbS * 4 + 1 neighbouring samples p[x][y] that are constructed samples prior to the deblocking filter process, with x = -1, y = -1..nTbS * 2 – 1 and x = 0..nTbS * 2 – 1, y = -1, are derived as follows:

- The neighbouring location (xNbCmp, yNbCmp) is specified by:

$$(xNbCmp, yNbCmp) = (xTbCmp + x, yTbCmp + y) \quad (8-33)$$

- The current luma location (xTbY, yTbY) and the neighbouring luma location (xNbY, yNbY) are derived as follows:

$$(xTbY, yTbY) = (cIdx == 0) ? (xTbCmp, yTbCmp) : (xTbCmp * SubWidthC, yTbCmp * SubHeightC) \quad (8-34)$$

$$(xNbY, yNbY) = (cIdx == 0) ? (xNbCmp, yNbCmp) : (xNbCmp * SubWidthC, yNbCmp * SubHeightC) \quad (8-35)$$

- The availability derivation process for a block in z-scan order as specified in clause 6.4.1 is invoked with the current luma location (xCurr, yCurr) set equal to (xTbY, yTbY) and the neighbouring luma location (xNbY, yNbY) as inputs, and the output is assigned to availableN.
- Each sample p[x][y] is derived as follows:
 - If one or more of the following conditions are true, the sample p[x][y] is marked as "not available for intra prediction":
 - The variable availableN is equal to FALSE.
 - CuPredMode[xNbY][yNbY] is not equal to MODE_INTRA and constrained_intra_pred_flag is equal to 1.
 - Otherwise, the sample p[x][y] is marked as "available for intra prediction" and the sample at the location (xNbCmp, yNbCmp) is assigned to p[x][y].

When at least one sample p[x][y] with x = -1, y = -1..nTbS * 2 – 1 and x = 0..nTbS * 2 – 1, y = -1 is marked as "not available for intra prediction", the reference sample substitution process for intra sample prediction in clause 8.4.4.2.2 is invoked with the samples p[x][y] with x = -1, y = -1..nTbS * 2 – 1 and x = 0..nTbS * 2 – 1, y = -1, nTbS and cIdx as inputs, and the modified samples p[x][y] with x = -1, y = -1..nTbS * 2 – 1 and x = 0..nTbS * 2 – 1, y = -1 as output.

Depending on the value of predModeIntra, the following ordered steps apply:

1. When `intra_smoothing_disabled_flag` is equal to 0 and either `cIdx` is equal to 0 or `ChromaArrayType` is equal to 3, the filtering process of neighbouring samples specified in clause 8.4.4.2.3 is invoked with the sample array `p`, the transform block size `nTbS` and the colour component index `cIdx` as inputs, and the output is reassigned to the sample array `p`.
2. The intra sample prediction process according to `predModeIntra` applies as follows:
 - If `predModeIntra` is equal to `INTRA_PLANAR`, the corresponding intra prediction mode specified in clause 8.4.4.2.4 is invoked with the sample array `p` and the transform block size `nTbS` as inputs, and the output is the predicted sample array `predSamples`.
 - Otherwise, if `predModeIntra` is equal to `INTRA_DC`, the corresponding intra prediction mode specified in clause 8.4.4.2.5 is invoked with the sample array `p`, the transform block size `nTbS` and the colour component index `cIdx` as inputs, and the output is the predicted sample array `predSamples`.
 - Otherwise (`predModeIntra` is in the range of `INTRA_ANGULAR2..INTRA_ANGULAR34`), the corresponding intra prediction mode specified in clause 8.4.4.2.6 is invoked with the intra prediction mode `predModeIntra`, the sample array `p`, the transform block size `nTbS` and the colour component index `cIdx` as inputs, and the output is the predicted sample array `predSamples`.

8.4.4.2.2 Reference sample substitution process for intra sample prediction

Inputs to this process are:

- reference samples `p[x][y]` with $x = -1, y = -1..nTbS * 2 - 1$ and $x = 0..nTbS * 2 - 1, y = -1$ for intra sample prediction,
- a transform block size `nTbS`, and
- a variable `cIdx` specifying the colour component of the current block.

Outputs of this process are the modified reference samples `p[x][y]` with $x = -1, y = -1..nTbS * 2 - 1$ and $x = 0..nTbS * 2 - 1, y = -1$ for intra sample prediction.

The variable `bitDepth` is derived as follows:

- If `cIdx` is equal to 0, `bitDepth` is set equal to `BitDepthY`.
- Otherwise, `bitDepth` is set equal to `BitDepthC`.

The values of the samples `p[x][y]` with $x = -1, y = -1..nTbS * 2 - 1$ and $x = 0..nTbS * 2 - 1, y = -1$ are modified as follows:

- If all samples `p[x][y]` with $x = -1, y = -1..nTbS * 2 - 1$ and $x = 0..nTbS * 2 - 1, y = -1$ are marked as "not available for intra prediction", the value $1 \ll (\text{bitDepth} - 1)$ is substituted for the values of all samples `p[x][y]`.
- Otherwise (at least one but not all samples `p[x][y]` are marked as "not available for intra prediction"), the following ordered steps are performed:
 1. When `p[-1][nTbS * 2 - 1]` is marked as "not available for intra prediction", search sequentially starting from $x = -1, y = nTbS * 2 - 1$ to $x = -1, y = -1$, then from $x = 0, y = -1$ to $x = nTbS * 2 - 1, y = -1$. Once a sample `p[x][y]` marked as "available for intra prediction" is found, the search is terminated and the value of `p[x][y]` is assigned to `p[-1][nTbS * 2 - 1]`.
 2. Search sequentially starting from $x = -1, y = nTbS * 2 - 2$ to $x = -1, y = -1$, when `p[x][y]` is marked as "not available for intra prediction", the value of `p[x][y + 1]` is substituted for the value of `p[x][y]`.
 3. For $x = 0..nTbS * 2 - 1, y = -1$, when `p[x][y]` is marked as "not available for intra prediction", the value of `p[x - 1][y]` is substituted for the value of `p[x][y]`.

All samples `p[x][y]` with $x = -1, y = -1..nTbS * 2 - 1$ and $x = 0..nTbS * 2 - 1, y = -1$ are marked as "available for intra prediction".

8.4.4.2.3 Filtering process of neighbouring samples

Inputs to this process are:

- the neighbouring samples `p[x][y]`, with $x = -1, y = -1..nTbS * 2 - 1$ and $x = 0..nTbS * 2 - 1, y = -1$,
- a variable `nTbS` specifying the transform block size.

Outputs of this process are the filtered samples `pF[x][y]`, with $x = -1, y = -1..nTbS * 2 - 1$ and $x = 0..nTbS * 2 - 1, y = -1$.

The variable filterFlag is derived as follows:

- If one or more of the following conditions are true, filterFlag is set equal to 0:
 - predModeIntra is equal to INTRA_DC.
 - nTbS is equal to 4.
- Otherwise, the following applies:
 - The variable minDistVerHor is set equal to $\text{Min}(\text{Abs}(\text{predModeIntra} - 26), \text{Abs}(\text{predModeIntra} - 10))$.
 - The variable intraHorVerDistThres[nTbS] is specified in Table 8-4.
 - The variable filterFlag is derived as follows:
 - If minDistVerHor is greater than intraHorVerDistThres[nTbS], filterFlag is set equal to 1.
 - Otherwise, filterFlag is set equal to 0.

Table 8-4 – Specification of intraHorVerDistThres[nTbS] for various transform block sizes

	nTbS = 8	nTbS = 16	nTbS = 32
intraHorVerDistThres[nTbS]	7	1	0

When filterFlag is equal to 1, the following applies:

- The variable biIntFlag is derived as follows:
 - If all of the following conditions are true, biIntFlag is set equal to 1:
 - strong_intra_smoothing_enabled_flag is equal to 1.
 - cIdx is equal to 0.
 - nTbS is equal to 32.
 - $\text{Abs}(p[-1][-1] + p[\text{nTbS} * 2 - 1][-1] - 2 * p[\text{nTbS} - 1][-1]) \text{ is less than } 1 \ll (\text{BitDepth}_Y - 5)$.
 - $\text{Abs}(p[-1][-1] + p[-1][\text{nTbS} * 2 - 1] - 2 * p[-1][\text{nTbS} - 1]) \text{ is less than } 1 \ll (\text{BitDepth}_Y - 5)$.
 - Otherwise, biIntFlag is set equal to 0.
- The filtering is performed as follows:
 - If biIntFlag is equal to 1, the filtered sample values pF[x][y] with $x = -1, y = -1..63$ and $x = 0..63, y = -1$ are derived as follows:

$$pF[-1][-1] = p[-1][-1] \quad (8-36)$$

$$pF[-1][y] = ((63 - y) * p[-1][-1] + (y + 1) * p[-1][63] + 32) \gg 6 \text{ for } y = 0..62 \quad (8-37)$$

$$pF[-1][63] = p[-1][63] \quad (8-38)$$

$$pF[x][-1] = ((63 - x) * p[-1][-1] + (x + 1) * p[63][-1] + 32) \gg 6 \text{ for } x = 0..62 \quad (8-39)$$

$$pF[63][-1] = p[63][-1] \quad (8-40)$$

- Otherwise (biIntFlag is equal to 0), the filtered sample values pF[x][y] with $x = -1, y = -1..nTbS * 2 - 1$ and $x = 0..nTbS * 2 - 1, y = -1$ are derived as follows:

$$pF[-1][-1] = (p[-1][0] + 2 * p[-1][-1] + p[0][-1] + 2) \gg 2 \quad (8-41)$$

$$pF[-1][y] = (p[-1][y + 1] + 2 * p[-1][y] + p[-1][y - 1] + 2) \gg 2 \text{ for } y = 0..nTbS * 2 - 2 \quad (8-42)$$

$$pF[-1][\text{nTbS} * 2 - 1] = p[-1][\text{nTbS} * 2 - 1] \quad (8-43)$$

$$pF[x][y] = (p[x-1][y] + 2 * p[x][y-1] + p[x+1][y] + 2) >> 2 \text{ for } x = 0..nTbS * 2 - 2 \quad (8-44)$$

$$pF[nTbS * 2 - 1][y] = p[nTbS * 2 - 1][y-1] \quad (8-45)$$

8.4.4.2.4 Specification of intra prediction mode INTRA_PLANAR

Inputs to this process are:

- the neighbouring samples $p[x][y]$, with $x = -1, y = -1..nTbS * 2 - 1$ and $x = 0..nTbS * 2 - 1, y = -1$,
- a variable $nTbS$ specifying the transform block size.

Outputs of this process are the predicted samples $predSamples[x][y]$, with $x, y = 0..nTbS - 1$.

The values of the prediction samples $predSamples[x][y]$, with $x, y = 0..nTbS - 1$, are derived as follows:

$$predSamples[x][y] = ((nTbS - 1 - x) * p[-1][y] + (x + 1) * p[nTbS][y-1] + (nTbS - 1 - y) * p[x][y-1] + (y + 1) * p[-1][nTbS] + nTbS) >> (Log2(nTbS) + 1) \quad (8-46)$$

8.4.4.2.5 Specification of intra prediction mode INTRA_DC

Inputs to this process are:

- the neighbouring samples $p[x][y]$, with $x = -1, y = -1..nTbS * 2 - 1$ and $x = 0..nTbS * 2 - 1, y = -1$,
- a variable $nTbS$ specifying the transform block size,
- a variable $cIdx$ specifying the colour component of the current block.

Outputs of this process are the predicted samples $predSamples[x][y]$, with $x, y = 0..nTbS - 1$.

The values of the prediction samples $predSamples[x][y]$, with $x, y = 0..nTbS - 1$, are derived by the following ordered steps:

1. A variable $dcVal$ is derived as follows:

$$dcVal = \left(\sum_{x'=0}^{nTbS-1} p[x'][y-1] + \sum_{y'=0}^{nTbS-1} p[-1][y'] + nTbS \right) >> (k + 1) \quad (8-47)$$

where $k = Log2(nTbS)$.

2. Depending on the value of the colour component index $cIdx$, the following applies:

- If $cIdx$ is equal to 0, $intra_boundary_filtering_disabled_flag$ is equal to 0, and $nTbS$ is less than 32, the following applies:

$$predSamples[0][0] = (p[-1][0] + 2 * dcVal + p[0][y-1] + 2) >> 2 \quad (8-48)$$

$$predSamples[x][0] = (p[x][y-1] + 3 * dcVal + 2) >> 2, \text{ with } x = 1..nTbS - 1 \quad (8-49)$$

$$predSamples[0][y] = (p[-1][y] + 3 * dcVal + 2) >> 2, \text{ with } y = 1..nTbS - 1 \quad (8-50)$$

$$predSamples[x][y] = dcVal, \text{ with } x, y = 1..nTbS - 1 \quad (8-51)$$

- Otherwise, the prediction samples $predSamples[x][y]$ are derived as follows:

$$predSamples[x][y] = dcVal, \text{ with } x, y = 0..nTbS - 1 \quad (8-52)$$

8.4.4.2.6 Specification of intra prediction mode in the range of INTRA_ANGULAR2.. INTRA_ANGULAR34

Inputs to this process are:

- the intra prediction mode $predModeIntra$,

- the neighbouring samples $p[x][y]$, with $x = -1, y = -1..nTbS * 2 - 1$ and $x = 0..nTbS * 2 - 1, y = -1$,
- a variable $nTbS$ specifying the transform block size,
- a variable $cIdx$ specifying the colour component of the current block.

Outputs of this process are the predicted samples $predSamples[x][y]$, with $x, y = 0..nTbS - 1$.

Figure 8-2 illustrates the total 33 intra angles and Table 8-5 specifies the mapping table between $predModeIntra$ and the angle parameter $intraPredAngle$.

Figure 8-2 – Intra prediction angle definition (informative)

Table 8-5 – Specification of $intraPredAngle$

predModeIntra	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17
intraPredAngle	-	32	26	21	17	13	9	5	2	0	-2	-5	-9	-13	-17	-21	-26
predModeIntra	18	19	20	21	22	23	24	25	26	27	28	29	30	31	32	33	34
intraPredAngle	-32	-26	-21	-17	-13	-9	-5	-2	0	2	5	9	13	17	21	26	32

Table 8-6 further specifies the mapping table between $predModeIntra$ and the inverse angle parameter $invAngle$.

Table 8-6 – Specification of $invAngle$

predModeIntra	11	12	13	14	15	16	17	18
invAngle	-4 096	-1 638	-910	-630	-482	-390	-315	-256
predModeIntra	19	20	21	22	23	24	25	26
invAngle	-315	-390	-482	-630	-910	-1 638	-4 096	-

The variable `disableIntraBoundaryFilter` is derived as follows:

- If `intra_boundary_filtering_disabled_flag` is equal to 1, `disableIntraBoundaryFilter` is set equal to 1.
- Otherwise (`intra_boundary_filtering_disabled_flag` is equal to 0), if `implicit_rdpem_enabled_flag` and `cu_transquant_bypass_flag` are both equal to 1, `disableIntraBoundaryFilter` is set equal to 1.
- Otherwise, `disableIntraBoundaryFilter` is set equal to 0.

The values of the prediction samples `predSamples[x][y]`, with $x, y = 0..nTbS - 1$ are derived as follows:

- If `predModeIntra` is greater than or equal to 18, the following ordered steps apply:

1. The reference sample array `ref[x]` is specified as follows:

- The following applies:

$$\text{ref}[x] = p[-1 + x][-1], \text{ with } x = 0..nTbS \quad (8-53)$$

- If `intraPredAngle` is less than 0, the main reference sample array is extended as follows:

- When $(nTbS * \text{intraPredAngle}) \gg 5$ is less than -1 ,

$$\begin{aligned} \text{ref}[x] &= p[-1][-1 + ((x * \text{invAngle} + 128) \gg 8)], \\ &\text{with } x = -1..(nTbS * \text{intraPredAngle}) \gg 5 \end{aligned} \quad (8-54)$$

- Otherwise,

$$\text{ref}[x] = p[-1 + x][-1], \text{ with } x = nTbS + 1..2 * nTbS \quad (8-55)$$

2. The values of the prediction samples `predSamples[x][y]`, with $x, y = 0..nTbS - 1$ are derived as follows:

- a. The index variable `iIdx` and the multiplication factor `iFact` are derived as follows:

$$\text{iIdx} = ((y + 1) * \text{intraPredAngle}) \gg 5 \quad (8-56)$$

$$\text{iFact} = ((y + 1) * \text{intraPredAngle}) \& 31 \quad (8-57)$$

- b. Depending on the value of `iFact`, the following applies:

- If `iFact` is not equal to 0, the value of the prediction samples `predSamples[x][y]` is derived as follows:

$$\begin{aligned} \text{predSamples}[x][y] &= \\ &((32 - \text{iFact}) * \text{ref}[x + \text{iIdx} + 1] + \text{iFact} * \text{ref}[x + \text{iIdx} + 2] + 16) \gg 5 \end{aligned} \quad (8-58)$$

- Otherwise, the value of the prediction samples `predSamples[x][y]` is derived as follows:

$$\text{predSamples}[x][y] = \text{ref}[x + \text{iIdx} + 1] \quad (8-59)$$

- c. When `predModeIntra` is equal to 26 (vertical), `cIdx` is equal to 0, `nTbS` is less than 32, and `disableIntraBoundaryFilter` is equal to 0, the following filtering applies with $x = 0, y = 0..nTbS - 1$:

$$\text{predSamples}[x][y] = \text{Clip1}_V(p[x][-1] + ((p[-1][y] - p[-1][-1]) \gg 1)) \quad (8-60)$$

- Otherwise (`predModeIntra` is less than 18), the following ordered steps apply:

1. The reference sample array `ref[x]` is specified as follows:

- The following applies:

$$\text{ref}[x] = p[-1][-1 + x], \text{ with } x = 0..nTbS \quad (8-61)$$

- If `intraPredAngle` is less than 0, the main reference sample array is extended as follows:

- When $(nTbS * \text{intraPredAngle}) \gg 5$ is less than -1 ,

$$\begin{aligned} \text{ref}[x] &= p[-1 + ((x * \text{invAngle} + 128) \gg 8)][-1], \\ &\text{with } x = -1..(nTbS * \text{intraPredAngle}) \gg 5 \end{aligned} \quad (8-62)$$

– Otherwise,

$$\text{ref}[x] = p[-1][-1 + x], \text{ with } x = nTbS + 1..2 * nTbS \quad (8-63)$$

2. The values of the prediction samples $\text{predSamples}[x][y]$, with $x, y = 0..nTbS - 1$ are derived as follows:

a. The index variable $iIdx$ and the multiplication factor $iFact$ are derived as follows:

$$iIdx = ((x + 1) * \text{intraPredAngle}) \gg 5 \quad (8-64)$$

$$iFact = ((x + 1) * \text{intraPredAngle}) \& 31 \quad (8-65)$$

b. Depending on the value of $iFact$, the following applies:

– If $iFact$ is not equal to 0, the value of the prediction samples $\text{predSamples}[x][y]$ is derived as follows:

$$\begin{aligned} \text{predSamples}[x][y] &= \\ &((32 - iFact) * \text{ref}[y + iIdx + 1] + iFact * \text{ref}[y + iIdx + 2] + 16) \gg 5 \end{aligned} \quad (8-66)$$

– Otherwise, the value of the prediction samples $\text{predSamples}[x][y]$ is derived as follows:

$$\text{predSamples}[x][y] = \text{ref}[y + iIdx + 1] \quad (8-67)$$

c. When predModeIntra is equal to 10 (horizontal), $cIdx$ is equal to 0, $nTbS$ is less than 32 and $\text{disableIntraBoundaryFilter}$ is equal to 0, the following filtering applies with $x = 0..nTbS - 1, y = 0$:

$$\text{predSamples}[x][y] = \text{Clip1}_Y(p[-1][y] + ((p[x][-1] - p[-1][-1]) \gg 1)) \quad (8-68)$$

8.4.4.2.7 Decoding process for palette mode

Inputs to this process are:

- a location (xCb, yCb) specifying the top-left luma sample of the current block relative to the top-left luma sample of the current picture,
- a variable $cIdx$ specifying the colour component of the current block,
- two variables $nCbSX$ and $nCbSY$ specifying the width and height of the current block, respectively.

Output of this process is an array $\text{recSamples}[x][y]$, with $x = 0..nCbSX - 1, y = 0..nCbSY - 1$ specifying reconstructed sample values for the block.

Depending on the value of $cIdx$, the variables $nSubWidth$ and $nSubHeight$ are derived as follows:

- If $cIdx$ is equal to 0, $nSubWidth$ is set to 1 and $nSubHeight$ is set to 1.
- Otherwise, $nSubWidth$ is set to SubWidthC and $nSubHeight$ is set to SubHeightC .

The $(nCbSX \times nCbSY)$ block of the reconstructed sample array recSamples at location (xCb, yCb) is represented by $\text{recSamples}[x][y]$ with $x = 0..nCbSX - 1$ and $y = 0..nCbSY - 1$, and the value of $\text{recSamples}[x][y]$ for each x in the range of 0 to $nCbSX - 1$, inclusive, and each y in the range of 0 to $nCbSY - 1$, inclusive, is derived as follows:

– The variables xL and yL are derived as follows:

$$xL = \text{palette_transpose_flag} ? y * nSubHeight : x * nSubWidth \quad (8-69)$$

$$yL = \text{palette_transpose_flag} ? x * nSubWidth : y * nSubHeight \quad (8-70)$$

– The variable $bIsEscapeSample$ is derived as follows:

- If $\text{PaletteIndexMap}[x_{Cb} + x_L][y_{Cb} + y_L]$ is equal to MaxPaletteIndex and $\text{palette_escape_val_present_flag}$ is equal to 1, bIsEscapeSample is set equal to 1.
- Otherwise, bIsEscapeSample is set equal to 0.
- If bIsEscapeSample is equal to 0, the following applies:

$$\text{recSamples}[x][y] = \text{CurrentPaletteEntries}[cIdx][\text{PaletteIndexMap}[x_{Cb} + x_L][y_{Cb} + y_L]] \quad (8-71)$$

- Otherwise, if $\text{cu_transquant_bypass_flag}$ is equal to 1, the following applies:

$$\text{recSamples}[x][y] = \text{PaletteEscapeVal}[cIdx][x_{Cb} + x_L][y_{Cb} + y_L] \quad (8-72)$$

- Otherwise (bIsEscapeSample is equal to 1 and $\text{cu_transquant_bypass_flag}$ is equal to 0), the following ordered steps apply:
 1. The derivation process for quantization parameters as specified in clause 8.6.1 is invoked with the location (x_{Cb}, y_{Cb}) specifying the top-left sample of the current block relative to the top-left sample of the current picture.
 2. The quantization parameter qP is derived as follows:
 - If $cIdx$ is equal to 0,

$$qP = \text{Max}(0, Qp'Y) \quad (8-73)$$

- Otherwise, if $cIdx$ is equal to 1,

$$qP = \text{Max}(0, Qp'Cb) \quad (8-74)$$

- Otherwise ($cIdx$ is equal to 2),

$$qP = \text{Max}(0, Qp'Cr) \quad (8-75)$$

3. The variable bitDepth is derived as follows:

$$\text{bitDepth} = (cIdx == 0) ? \text{BitDepth}_Y : \text{BitDepth}_C \quad (8-76)$$

4. The list $\text{levelScale}[]$ is specified as $\text{levelScale}[k] = \{40, 45, 51, 57, 64, 72\}$ with $k = 0..5$.

5. The following applies:

$$\text{tmpVal} = (\text{PaletteEscapeVal}[cIdx][x_{Cb} + x_L][y_{Cb} + y_L] * \text{levelScale}[qP \% 6]) \ll ((qP / 6) + 32) \gg 6 \quad (8-77)$$

$$\text{recSamples}[x][y] = \text{Clip3}(0, (1 \ll \text{bitDepth}) - 1, \text{tmpVal}) \quad (8-78)$$

The variable $\text{PredictorPaletteSize}$ and the array $\text{PredictorPaletteEntries}$ are derived or modified as follows:

```

numComps = ( ChromaArrayType == 0 ) ? 1 : 3
for( i = 0; i < CurrentPaletteSize; i++ )
    for( cIdx = 0; cIdx < numComps; cIdx++ )
        newPredictorPaletteEntries[ cIdx ][ i ] = CurrentPaletteEntries[ cIdx ][ i ]
newPredictorPaletteSize = CurrentPaletteSize
for( i = 0; i < PredictorPaletteSize && newPredictorPaletteSize < PaletteMaxPredictorSize; i++ )
    if( !PalettePredictorEntryReuseFlags[ i ] ) {
        for( cIdx = 0; cIdx < numComps; cIdx++ )
            newPredictorPaletteEntries[ cIdx ][ newPredictorPaletteSize ] =
                PredictorPaletteEntries[ cIdx ][ i ]
        newPredictorPaletteSize++
    }
for( cIdx = 0; cIdx < numComps; cIdx++ )

```

```

for( i = 0; i < newPredictorPaletteSize; i++ )
    PredictorPaletteEntries[ cIdx ][ i ] = newPredictorPaletteEntries[ cIdx ][ i ]
PredictorPaletteSize = newPredictorPaletteSize

```

It is a requirement of bitstream conformance that the value of PredictorPaletteSize shall be in the range of 0 to PaletteMaxPredictorSize, inclusive.

8.5 Decoding process for coding units coded in inter prediction mode

8.5.1 General decoding process for coding units coded in inter prediction mode

Inputs to this process are:

- a luma location (xCb, yCb) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a variable log2CbSize specifying the size of the current coding block.

Output of this process is a modified reconstructed picture before deblocking filtering.

The derivation process for quantization parameters as specified in clause 8.6.1 is invoked with the luma location (xCb, yCb) as input.

The variable nCbS_L is set equal to $1 \ll \log_2 \text{CbSize}$. When ChromaArrayType is not equal to 0, the variable nCbSw_C is set equal to $(1 \ll \log_2 \text{CbSize}) / \text{SubWidthC}$ and the variable nCbSh_C is set equal to $(1 \ll \log_2 \text{CbSize}) / \text{SubHeightC}$.

The decoding process for coding units coded in inter prediction mode consists of the following ordered steps:

1. The inter prediction process as specified in clause 8.5.2 is invoked with the luma location (xCb, yCb) and the luma coding block size log2CbSize as inputs, and the outputs are the array predSamples_L and, when ChromaArrayType is not equal to 0, the arrays predSamples_{Cb} and predSamples_{Cr}.
2. The decoding process for the residual signal of coding units coded in inter prediction mode specified in clause 8.5.4 is invoked with the luma location (xCb, yCb) and the luma coding block size log2CbSize as inputs, and the outputs are the array resSamples_L and, when ChromaArrayType is not equal to 0, the arrays resSamples_{Cb} and resSamples_{Cr}.
3. The reconstructed samples of the current coding unit are derived as follows:
 - The picture construction process prior to in-loop filtering for a colour component as specified in clause 8.6.7 is invoked with the luma coding block location (xCb, yCb), the variable nCurrSw set equal to nCbS_L, the variable nCurrSh set equal to nCbS_L, the variable cIdx set equal to 0, the (nCbS_L)x(nCbS_L) array predSamples set equal to predSamples_L and the (nCbS_L)x(nCbS_L) array resSamples set equal to resSamples_L as inputs.
 - When ChromaArrayType is not equal to 0, the picture construction process prior to in-loop filtering for a colour component as specified in clause 8.6.7 is invoked with the chroma coding block location (xCb / SubWidthC, yCb / SubHeightC), the variable nCurrSw set equal to nCbSw_C, the variable nCurrSh set equal to nCbSh_C, the variable cIdx set equal to 1, the (nCbSw_C)x(nCbSh_C) array predSamples set equal to predSamples_{Cb} and the (nCbSw_C)x(nCbSh_C) array resSamples set equal to resSamples_{Cb} as inputs.
 - When ChromaArrayType is not equal to 0, the picture construction process prior to in-loop filtering for a colour component as specified in clause 8.6.7 is invoked with the chroma coding block location (xCb / SubWidthC, yCb / SubHeightC), the variable nCurrSw set equal to nCbSw_C, the variable nCurrSh set equal to nCbSh_C, the variable cIdx set equal to 2, the (nCbSw_C)x(nCbSh_C) array predSamples set equal to predSamples_{Cr} and the (nCbSw_C)x(nCbSh_C) array resSamples set equal to resSamples_{Cr} as inputs.

8.5.2 Inter prediction process

This process is invoked when decoding coding unit whose CuPredMode[xCb][yCb] is not equal to MODE_INTRA.

Inputs to this process are:

- a luma location (xCb, yCb) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a variable log2CbSize specifying the size of the current luma coding block.

Outputs of this process are:

- an (nCbS_L)x(nCbS_L) array predSamples_L of luma prediction samples, where nCbS_L is derived as specified below,

- when ChromaArrayType is not equal to 0, an $(nCbSw_C) \times (nCbSh_C)$ array $predSamples_{Cb}$ of chroma prediction samples for the component Cb, where $nCbSw_C$ and $nCbSh_C$ are derived as specified below,
- when ChromaArrayType is not equal to 0, an $(nCbSw_C) \times (nCbSh_C)$ array $predSamples_{Cr}$ of chroma prediction samples for the component Cr, where $nCbSw_C$ and $nCbSh_C$ are derived as specified below.

The variable $nCbS_L$ is set equal to $1 \ll \log_2 CbSize$. When ChromaArrayType is not equal to 0, the variable $nCbSw_C$ is set equal to $nCbS_L / SubWidthC$ and the variable $nCbSh_C$ is set equal to $nCbS_L / SubHeightC$.

The variable $nCbS_{1L}$ is set equal to $nCbS_L \gg 1$.

Depending on the value of PartMode, the following applies:

- If PartMode is equal to PART_2Nx2N, the decoding process for prediction units in inter prediction mode as specified in clause 8.5.3 is invoked with the luma location (xCb, yCb), the luma location (xBI, yBI) set equal to (0, 0), the size of the luma coding block $nCbS_L$, the width of the luma prediction block $nPbW$ set equal to $nCbS_L$, the height of the luma prediction block $nPbH$ set equal to $nCbS_L$ and a partition index $partIdx$ set equal to 0 as inputs, and the outputs are an $(nCbS_L) \times (nCbS_L)$ array $predSamples_L$ and, when ChromaArrayType is not equal to 0, two $(nCbSw_C) \times (nCbSh_C)$ arrays $predSamples_{Cb}$ and $predSamples_{Cr}$.
- Otherwise, if PartMode is equal to PART_2NxN, the following ordered steps apply:
 1. The decoding process for prediction units in inter prediction mode as specified in clause 8.5.3 is invoked with the luma location (xCb, yCb), the luma location (xBI, yBI) set equal to (0, 0), the size of the luma coding block $nCbS_L$, the width of the luma prediction block $nPbW$ set equal to $nCbS_L$, the height of the luma prediction block $nPbH$ set equal to $nCbS_L \gg 1$ and a partition index $partIdx$ set equal to 0 as inputs, and the outputs are an $(nCbS_L) \times (nCbS_L)$ array $predSamples_L$ and, when ChromaArrayType is not equal to 0, two $(nCbSw_C) \times (nCbSh_C)$ arrays $predSamples_{Cb}$ and $predSamples_{Cr}$.
 2. The decoding process for prediction units in inter prediction mode as specified in clause 8.5.3 is invoked with the luma location (xCb, yCb), the luma location (xBI, yBI) set equal to (0, $nCbS_L \gg 1$), the size of the luma coding block $nCbS_L$, the width of the luma prediction block $nPbW$ set equal to $nCbS_L$, the height of the luma prediction block $nPbH$ set equal to $nCbS_L \gg 1$ and a partition index $partIdx$ set equal to 1 as inputs, and the outputs are the modified $(nCbS_L) \times (nCbS_L)$ array $predSamples_L$ and, when ChromaArrayType is not equal to 0, the two modified $(nCbSw_C) \times (nCbSh_C)$ arrays $predSamples_{Cb}$ and $predSamples_{Cr}$.
- Otherwise, if PartMode is equal to PART_Nx2N, the following ordered steps apply:
 1. The decoding process for prediction units in inter prediction mode as specified in clause 8.5.3 is invoked with the luma location (xCb, yCb), the luma location (xBI, yBI) set equal to (0, 0), the size of the luma coding block $nCbS_L$, the width of the luma prediction block $nPbW$ set equal to $nCbS_L \gg 1$, the height of the luma prediction block $nPbH$ set equal to $nCbS_L$ and a partition index $partIdx$ set equal to 0 as inputs, and the outputs are an $(nCbS_L) \times (nCbS_L)$ array $predSamples_L$ and, when ChromaArrayType is not equal to 0, two $(nCbSw_C) \times (nCbSh_C)$ arrays $predSamples_{Cb}$ and $predSamples_{Cr}$.
 2. The decoding process for prediction units in inter prediction mode as specified in clause 8.5.3 is invoked with the luma location (xCb, yCb), the luma location (xBI, yBI) set equal to ($nCbS_L \gg 1$, 0), the size of the luma coding block $nCbS_L$, the width of the luma prediction block $nPbW$ set equal to $nCbS_L \gg 1$, the height of the luma prediction block $nPbH$ set equal to $nCbS_L$ and a partition index $partIdx$ set equal to 1 as inputs, and the outputs are the modified $(nCbS_L) \times (nCbS_L)$ array $predSamples_L$ and, when ChromaArrayType is not equal to 0, the two modified $(nCbSw_C) \times (nCbSh_C)$ arrays $predSamples_{Cb}$ and $predSamples_{Cr}$.
- Otherwise, if PartMode is equal to PART_2NxN_U, the following ordered steps apply:
 1. The decoding process for prediction units in inter prediction mode as specified in clause 8.5.3 is invoked with the luma location (xCb, yCb), the luma location (xBI, yBI) set equal to (0, 0), the size of the luma coding block $nCbS_L$, the width of the luma prediction block $nPbW$ set equal to $nCbS_L$, the height of the luma prediction block $nPbH$ set equal to $nCbS_L \gg 2$ and a partition index $partIdx$ set equal to 0 as inputs, and the outputs are an $(nCbS_L) \times (nCbS_L)$ array $predSamples_L$ and, when ChromaArrayType is not equal to 0, two $(nCbSw_C) \times (nCbSh_C)$ arrays $predSamples_{Cb}$ and $predSamples_{Cr}$.
 2. The decoding process for prediction units in inter prediction mode as specified in clause 8.5.3 is invoked with the luma location (xCb, yCb), the luma location (xBI, yBI) set equal to (0, $nCbS_L \gg 2$), the size of the luma coding block $nCbS_L$, the width of the luma prediction block $nPbW$ set equal to $nCbS_L$, the height of the luma prediction block $nPbH$ set equal to $(nCbS_L \gg 1) + (nCbS_L \gg 2)$ and a partition index $partIdx$ set equal to 1 as inputs, and the outputs are the modified $(nCbS_L) \times (nCbS_L)$ array $predSamples_L$ and, when ChromaArrayType is not equal to 0, the two modified $(nCbSw_C) \times (nCbSh_C)$ arrays $predSamples_{Cb}$ and $predSamples_{Cr}$.
- Otherwise, if PartMode is equal to PART_2NxND, the following ordered steps apply:

- [illegible]

4. The decoding process for prediction units in inter prediction mode as specified in clause 8.5.3 is invoked with the luma location (x_{Cb} , y_{Cb}), the luma location (x_{Bl} , y_{Bl}) set equal to ($n_{CbS_L} \gg 1$, $n_{CbS_L} \gg 1$), the size of the luma coding block n_{CbS_L} , the width of the luma prediction block n_{PbW} set equal to $n_{CbS_L} \gg 1$, the height of the luma prediction block n_{PbH} set equal to $n_{CbS_L} \gg 1$ and a partition index $partIdx$ set equal to 3 as inputs, and the outputs are the modified $(n_{CbS_L}) \times (n_{CbS_L})$ array $predSamples_L$ and, when $ChromaArrayType$ is not equal to 0, the two modified $(n_{CbSw_C}) \times (n_{CbSh_C})$ arrays $predSamples_{Cb}$ and $predSamples_{Cr}$.

8.5.3 Decoding process for prediction units in inter prediction mode

8.5.3.1 General

Inputs to this process are:

- a luma location (x_{Cb} , y_{Cb}) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a luma location (x_{Bl} , y_{Bl}) specifying the top-left sample of the current luma prediction block relative to the top-left sample of the current luma coding block,
- a variable n_{CbS} specifying the size of the current luma coding block,
- a variable n_{PbW} specifying the width of the current luma prediction block,
- a variable n_{PbH} specifying the height of the current luma prediction block,
- a variable $partIdx$ specifying the index of the current prediction unit within the current coding unit.

Outputs of this process are:

- an $(n_{CbS_L}) \times (n_{CbS_L})$ array $predSamples_L$ of luma prediction samples, where n_{CbS_L} is derived as specified below,
- when $ChromaArrayType$ is not equal to 0, an $(n_{CbSw_C}) \times (n_{CbSh_C})$ array $predSamples_{Cb}$ of chroma prediction samples for the component Cb, where n_{CbSw_C} and n_{CbSh_C} are derived as specified below,
- when $ChromaArrayType$ is not equal to 0, an $(n_{CbSw_C}) \times (n_{CbSh_C})$ array $predSamples_{Cr}$ of chroma prediction samples for the component Cr, where n_{CbSw_C} and n_{CbSh_C} are derived as specified below.

The variable n_{CbS_L} is set equal to n_{CbS} . When $ChromaArrayType$ is not equal to 0, the variable n_{CbSw_C} is set equal to $n_{CbS} / SubWidthC$ and the variable n_{CbSh_C} is set equal to $n_{CbS} / SubHeightC$.

The decoding process for prediction units in inter prediction mode consists of the following ordered steps:

1. The derivation process for motion vector components and reference indices as specified in clause 8.5.3.2 is invoked with the luma coding block location (x_{Cb} , y_{Cb}), the luma prediction block location (x_{Bl} , y_{Bl}), the luma coding block size block n_{CbS} , the luma prediction block width n_{PbW} , the luma prediction block height n_{PbH} and the prediction unit index $partIdx$ as inputs, and the luma motion vectors $mvL0$ and $mvL1$, when $ChromaArrayType$ is not equal to 0, the chroma motion vectors $mvCL0$ and $mvCL1$, the reference indices $refIdxL0$ and $refIdxL1$ and the prediction list utilization flags $predFlagL0$ and $predFlagL1$ as outputs.
2. The decoding process for inter sample prediction as specified in clause 8.5.3.3 is invoked with the luma coding block location (x_{Cb} , y_{Cb}), the luma prediction block location (x_{Bl} , y_{Bl}), the luma coding block size block n_{CbS} , the luma prediction block width n_{PbW} , the luma prediction block height n_{PbH} , the luma motion vectors $mvL0$ and $mvL1$, when $ChromaArrayType$ is not equal to 0, the chroma motion vectors $mvCL0$ and $mvCL1$, the reference indices $refIdxL0$ and $refIdxL1$, and the prediction list utilization flags $predFlagL0$ and $predFlagL1$ as inputs, and the inter prediction samples ($predSamples$) that are an $(n_{CbS_L}) \times (n_{CbS_L})$ array $predSamples_L$ of prediction luma samples and, when $ChromaArrayType$ is not equal to 0, two $(n_{CbSw_C}) \times (n_{CbSh_C})$ arrays $predSamples_{Cb}$ and $predSamples_{Cr}$ of prediction chroma samples, one for each of the chroma components Cb and Cr, as outputs.

For use in derivation processes of variables invoked later in the decoding process, the following assignments are made for $x = x_{Bl}..x_{Bl} + n_{PbW} - 1$ and $y = y_{Bl}..y_{Bl} + n_{PbH} - 1$:

$$MvL0[x_{Cb} + x][y_{Cb} + y] = mvL0 \quad (8-80)$$

$$MvL1[x_{Cb} + x][y_{Cb} + y] = mvL1 \quad (8-81)$$

$$RefIdxL0[x_{Cb} + x][y_{Cb} + y] = refIdxL0 \quad (8-82)$$

$$RefIdxL1[x_{Cb} + x][y_{Cb} + y] = refIdxL1 \quad (8-83)$$

$$\text{PredFlagL0}[x_{Cb} + x][y_{Cb} + y] = \text{predFlagL0} \quad (8-84)$$

$$\text{PredFlagL1}[x_{Cb} + x][y_{Cb} + y] = \text{predFlagL1} \quad (8-85)$$

8.5.3.2 Derivation process for motion vector components and reference indices

8.5.3.2.1 General

Inputs to this process are:

- a luma location (x_{Cb} , y_{Cb}) of the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a luma location (x_{Bl} , y_{Bl}) of the top-left sample of the current luma prediction block relative to the top-left sample of the current luma coding block,
- a variable n_{CbS} specifying the size of the current luma coding block,
- two variables n_{PbW} and n_{PbH} specifying the width and the height of the luma prediction block,
- a variable $partIdx$ specifying the index of the current prediction unit within the current coding unit.

Outputs of this process are:

- the luma motion vectors $mvL0$ and $mvL1$,
- when $ChromaArrayType$ is not equal to 0, the chroma motion vectors $mvCL0$ and $mvCL1$,
- the reference indices $refIdxL0$ and $refIdxL1$,
- the prediction list utilization flags $predFlagL0$ and $predFlagL1$.

Let (x_{Pb} , y_{Pb}) specify the top-left sample location of the current luma prediction block relative to the top-left luma sample of the current picture where $x_{Pb} = x_{Cb} + x_{Bl}$ and $y_{Pb} = y_{Cb} + y_{Bl}$.

Let the variable LX be $RefPicListX$, with X being 0 or 1, of the current picture.

The variables n_{PbSw} , and n_{PbSh} are derived as follows:

$$n_{PbSw} = n_{CbS} / ((PartMode == PART_2Nx2N \parallel PartMode == PART_2NxN) ? 1 : 2) \quad (8-86)$$

$$n_{PbSh} = n_{CbS} / ((PartMode == PART_2Nx2N \parallel PartMode == PART_Nx2N) ? 1 : 2) \quad (8-87)$$

The function $LongTermRefPic(aPic, aPb, refIdx, LX)$, with X being 0 or 1, is defined as follows:

- If the picture with index $refIdx$ from reference picture list LX of the slice containing prediction block aPb in the picture $aPic$ was marked as "used for long-term reference" at the time when $aPic$ was the current picture, $LongTermRefPic(aPic, aPb, refIdx, LX)$ is equal to 1.
- Otherwise, $LongTermRefPic(aPic, aPb, refIdx, LX)$ is equal to 0.

For the derivation of the variables $mvL0$ and $mvL1$, $refIdxL0$ and $refIdxL1$, as well as $predFlagL0$ and $predFlagL1$, the following applies:

- If $merge_flag[x_{Pb}][y_{Pb}]$ is equal to 1, the derivation process for luma motion vectors for merge mode as specified in clause 8.5.3.2.2 is invoked with the luma location (x_{Cb} , y_{Cb}), the luma location (x_{Pb} , y_{Pb}), the variables n_{CbS} , n_{PbW} , n_{PbH} and the partition index $partIdx$ as inputs, and the output being the luma motion vectors $mvL0$, $mvL1$, the reference indices $refIdxL0$, $refIdxL1$ and the prediction list utilization flags $predFlagL0$ and $predFlagL1$.
- Otherwise, for X being replaced by either 0 or 1 in the variables $predFlagLX$, $mvLX$ and $refIdxLX$, in $PRED_LX$, and in the syntax elements ref_idx_LX and $MvdLX$, the following ordered steps apply:

1. The variables $refIdxLX$ and $predFlagLX$ are derived as follows:

- If $inter_pred_idc[x_{Pb}][y_{Pb}]$ is equal to $PRED_LX$ or $PRED_BI$,

$$refIdxLX = ref_idx_LX[x_{Pb}][y_{Pb}] \quad (8-88)$$

$$predFlagLX = 1 \quad (8-89)$$

- Otherwise, the variables $refIdxLX$ and $predFlagLX$ are specified by:

$$\text{refIdxLX} = -1 \quad (8-90)$$

$$\text{predFlagLX} = 0 \quad (8-91)$$

2. The variable `mvdLX` is derived as follows:

$$\text{mvdLX}[0] = \text{MvdLX}[\text{xPb}][\text{yPb}][0] \quad (8-92)$$

$$\text{mvdLX}[1] = \text{MvdLX}[\text{xPb}][\text{yPb}][1] \quad (8-93)$$

3. When `predFlagLX` is equal to 1, the derivation process for luma motion vector prediction in clause 8.5.3.2.6 is invoked with the luma coding block location (`xCb`, `yCb`), the coding block size `nCbS`, the luma prediction block location (`xPb`, `yPb`), the variables `nPbW`, `nPbH`, `refIdxLX` and the partition index `partIdx` as inputs, and the output being `mvpLX`.
4. When `predFlagLX` is equal to 1 and the picture with index `refIdx` from reference picture list `LX` of the slice is not the current picture, and `use_integer_mv_flag` is equal to 0, the luma motion vector `mvLX` is derived as follows:

$$\text{uLX}[0] = (\text{mvpLX}[0] + \text{mvdLX}[0] + 2^{16}) \% 2^{16} \quad (8-94)$$

$$\text{mvLX}[0] = (\text{uLX}[0] \geq 2^{15}) ? (\text{uLX}[0] - 2^{16}) : \text{uLX}[0] \quad (8-95)$$

$$\text{uLX}[1] = (\text{mvpLX}[1] + \text{mvdLX}[1] + 2^{16}) \% 2^{16} \quad (8-96)$$

$$\text{mvLX}[1] = (\text{uLX}[1] \geq 2^{15}) ? (\text{uLX}[1] - 2^{16}) : \text{uLX}[1] \quad (8-97)$$

NOTE 1– The resulting values of `mvLX[0]` and `mvLX[1]` as specified above will always be in the range of -2^{15} to $2^{15} - 1$, inclusive.

5. When `predFlagLX` is equal to 1 and the reference picture is the current picture, or when `predFlagLX` is equal to 1 and `use_integer_mv_flag` is equal to 1, the luma motion vector `mvLX` is derived as follows:

$$\text{uLX}[0] = (((\text{mvpLX}[0] \gg 2) + \text{mvdLX}[0]) \ll 2) + 2^{16}) \% 2^{16} \quad (8-98)$$

$$\text{mvLX}[0] = (\text{uLX}[0] \geq 2^{15}) ? (\text{uLX}[0] - 2^{16}) : \text{uLX}[0] \quad (8-99)$$

$$\text{uLX}[1] = (((\text{mvpLX}[1] \gg 2) + \text{mvdLX}[1]) \ll 2) + 2^{16}) \% 2^{16} \quad (8-100)$$

$$\text{mvLX}[1] = (\text{uLX}[1] \geq 2^{15}) ? (\text{uLX}[1] - 2^{16}) : \text{uLX}[1] \quad (8-101)$$

NOTE 2 – The resulting values of `mvLX[0]` and `mvLX[1]` as specified above will always be in the range of -2^{15} to $2^{15} - 1$, inclusive.

- The variable `noIntegerMvFlag` is derived as follows:

$$\text{noIntegerMvFlag} = !((\text{mvL0} \& 0x3 == 0) \mid (\text{mvL1} \& 0x3 == 0)) \quad (8-102)$$

- The variable `identicalMvs` is derived as follows:

$$\text{identicalMvs} = (\text{mvL0} == \text{mvL1}) \&\& (\text{DiffPicOrderCnt}(\text{RefPicList0}[\text{refIdxL0}], \text{RefPicList1}[\text{refIdxL1}]) == 0) \quad (8-103)$$

When all of the following conditions are true, `refIdxL1` is set equal to -1 and `predFlagL1` is set equal to 0.

- `predFlagL0` is equal to 1.
- `predFlagL1` is equal to 1.
- `nPbSw` is equal to 8.
- `nPbSh` is equal to 8.
- `TwoVersionsOfCurrDecPicFlag` is equal to 1.

- noIntegerMvFlag is equal to 1.
- identicalMvs is equal to 0.

When ChromaArrayType is not equal to 0 and predFlagLX, with X being 0 or 1, is equal to 1, the derivation process for chroma motion vectors in clause 8.5.3.2.10 is invoked with mvLX as input, and the output being mvCLX.

The variables offsetX and offsetY are derived as follows:

$$\text{offsetX} = (\text{ChromaArrayType} == 0) ? 0 : (\text{mvCLX}[0] \& 0x7 ? 2 : 0) \quad (8-104)$$

$$\text{offsetY} = (\text{ChromaArrayType} == 0) ? 0 : (\text{mvCLX}[1] \& 0x7 ? 2 : 0) \quad (8-105)$$

It is a requirement of bitstream conformance that when the reference picture is the current picture, the luma motion vector mvLX shall obey the following constraints:

- When the derivation process for z-scan order block availability as specified in clause 6.4.1 is invoked with (xCurr, yCurr) set equal to (xCb, yCb) and the neighbouring luma location (xNbY, yNbY) set equal to (xPb + (mvLX[0] >> 2) – offsetX, yPb + (mvLX[1] >> 2) – offsetY) as inputs, the output shall be equal to TRUE.
- When the derivation process for z-scan order block availability as specified in clause 6.4.1 is invoked with (xCurr, yCurr) set equal to (xCb, yCb) and the neighbouring luma location (xNbY, yNbY) set equal to (xPb + (mvLX[0] >> 2) + nPbW – 1 + offsetX, yPb + (mvLX[1] >> 2) + nPbH – 1 + offsetY) as inputs, the output shall be equal to TRUE.
- One or both of the following conditions shall be true:
 - The value of (mvLX[0] >> 2) + nPbW + xB1 + offsetX is less than or equal to 0.
 - The value of (mvLX[1] >> 2) + nPbH + yB1 + offsetY is less than or equal to 0.
- The following condition shall be true:

$$(\text{xPb} + (\text{mvLX}[0] \gg 2) + \text{nPbSw} - 1 + \text{offsetX}) / \text{CtbSizeY} - \text{xCb} / \text{CtbSizeY} \leq \text{yCb} / \text{CtbSizeY} - (\text{yPb} + (\text{mvLX}[1] \gg 2) + \text{nPbSh} - 1 + \text{offsetY}) / \text{CtbSizeY} \quad (8-106)$$

8.5.3.2.2 Derivation process for luma motion vectors for merge mode

This process is only invoked when merge_flag[xPb][yPb] is equal to 1, where (xPb, yPb) specify the top-left sample of the current luma prediction block relative to the top-left luma sample of the current picture.

Inputs to this process are:

- a luma location (xCb, yCb) of the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a luma location (xPb, yPb) of the top-left sample of the current luma prediction block relative to the top-left luma sample of the current picture,
- a variable nCbS specifying the size of the current luma coding block,
- two variables nPbW and nPbH specifying the width and the height of the luma prediction block,
- a variable partIdx specifying the index of the current prediction unit within the current coding unit.

Outputs of this process are:

- the luma motion vectors mvL0 and mvL1,
- the reference indices refIdxL0 and refIdxL1,
- the prediction list utilization flags predFlagL0 and predFlagL1.

The location (xOrigP, yOrigP) and the variables nOrigPbW and nOrigPbH are derived to store the values of (xPb, yPb), nPbW and nPbH as follows:

$$(\text{xOrigP}, \text{yOrigP}) \text{ is set equal to } (\text{xPb}, \text{yPb}) \quad (8-107)$$

$$\text{nOrigPbW} = \text{nPbW} \quad (8-108)$$

$$nOrigPbH = nPbH \quad (8-109)$$

When Log2ParMrgLevel is greater than 2 and nCbS is equal to 8, (xPb, yPb), nPbW, nPbH and partIdx are modified as follows:

$$(xPb, yPb) = (xCb, yCb) \quad (8-110)$$

$$nPbW = nCbS \quad (8-111)$$

$$nPbH = nCbS \quad (8-112)$$

$$partIdx = 0 \quad (8-113)$$

NOTE – When Log2ParMrgLevel is greater than 2 and nCbS is equal to 8, all the prediction units of the current coding unit share a single merge candidate list, which is identical to the merge candidate list of the 2Nx2N prediction unit.

The motion vectors mvL0 and mvL1, the reference indices refIdxL0 and refIdxL1 and the prediction utilization flags predFlagL0 and predFlagL1 are derived by the following ordered steps:

1. The derivation process for merging candidates from neighbouring prediction unit partitions in clause 8.5.3.2.3 is invoked with the luma coding block location (xCb, yCb), the coding block size nCbS, the luma prediction block location (xPb, yPb), the luma prediction block width nPbW, the luma prediction block height nPbH and the partition index partIdx as inputs, and the output being the availability flags availableFlagA₀, availableFlagA₁, availableFlagB₀, availableFlagB₁ and availableFlagB₂, the reference indices refIdxLXA₀, refIdxLXA₁, refIdxLXB₀, refIdxLXB₁ and refIdxLXB₂, the prediction list utilization flags predFlagLXA₀, predFlagLXA₁, predFlagLXB₀, predFlagLXB₁ and predFlagLXB₂, and the motion vectors mvLXA₀, mvLXA₁, mvLXB₀, mvLXB₁ and mvLXB₂, with X being 0 or 1.
2. The reference indices for the temporal merging candidate, refIdxLXCol, with X being 0 or 1, are set equal to 0.
3. The derivation process for temporal luma motion vector prediction in clause 8.5.3.2.8 is invoked with the luma location (xPb, yPb), the luma prediction block width nPbW, the luma prediction block height nPbH and the variable refIdxL0Col as inputs, and the output being the availability flag availableFlagL0Col and the temporal motion vector mvL0Col. The variables availableFlagCol, predFlagL0Col and predFlagL1Col are derived as follows:

$$availableFlagCol = availableFlagL0Col \quad (8-114)$$

$$predFlagL0Col = availableFlagL0Col \quad (8-115)$$

$$predFlagL1Col = 0 \quad (8-116)$$

4. When slice_type is equal to B, the derivation process for temporal luma motion vector prediction in clause 8.5.3.2.8 is invoked with the luma location (xPb, yPb), the luma prediction block width nPbW, the luma prediction block height nPbH and the variable refIdxL1Col as inputs, and the output being the availability flag availableFlagL1Col and the temporal motion vector mvL1Col. The variables availableFlagCol and predFlagL1Col are derived as follows:

$$availableFlagCol = availableFlagL0Col \ || \ availableFlagL1Col \quad (8-117)$$

$$predFlagL1Col = availableFlagL1Col \quad (8-118)$$

5. The merging candidate list, mergeCandList, is constructed as follows:

$$\begin{aligned} i &= 0 \\ \text{if}(availableFlagA_1) \\ &\quad mergeCandList[i++] = A_1 \\ \text{if}(availableFlagB_1) \\ &\quad mergeCandList[i++] = B_1 \\ \text{if}(availableFlagB_0) \\ &\quad mergeCandList[i++] = B_0 \\ \text{if}(availableFlagA_0) \\ &\quad mergeCandList[i++] = A_0 \end{aligned} \quad (8-119)$$

```

if( availableFlagB2 )
    mergeCandList[ i++ ] = B2
if( availableFlagCol )
    mergeCandList[ i++ ] = Col

```

6. The variable numCurrMergeCand and numOrigMergeCand are set equal to the number of merging candidates in the mergeCandList.
7. When slice_type is equal to B, the derivation process for combined bi-predictive merging candidates specified in clause 8.5.3.2.4 is invoked with mergeCandList, the reference indices refIdxL0N and refIdxL1N, the prediction list utilization flags predFlagL0N and predFlagL1N, the motion vectors mvL0N and mvL1N of every candidate N in mergeCandList, numCurrMergeCand and numOrigMergeCand as inputs, and the output is assigned to mergeCandList, numCurrMergeCand, the reference indices refIdxL0combCand_k and refIdxL1combCand_k, the prediction list utilization flags predFlagL0combCand_k and predFlagL1combCand_k and the motion vectors mvL0combCand_k and mvL1combCand_k of every new candidate combCand_k being added into mergeCandList. The number of candidates being added, numCombMergeCand, is set equal to (numCurrMergeCand – numOrigMergeCand). When numCombMergeCand is greater than 0, k ranges from 0 to numCombMergeCand – 1, inclusive.
8. The derivation process for zero motion vector merging candidates specified in clause 8.5.3.2.5 is invoked with the mergeCandList, the reference indices refIdxL0N and refIdxL1N, the prediction list utilization flags predFlagL0N and predFlagL1N, the motion vectors mvL0N and mvL1N of every candidate N in mergeCandList and numCurrMergeCand as inputs, and the output is assigned to mergeCandList, numCurrMergeCand, the reference indices refIdxL0zeroCand_m and refIdxL1zeroCand_m, the prediction list utilization flags predFlagL0zeroCand_m and predFlagL1zeroCand_m and the motion vectors mvL0zeroCand_m and mvL1zeroCand_m of every new candidate zeroCand_m being added into mergeCandList. The number of candidates being added, numZeroMergeCand, is set equal to (numCurrMergeCand – numOrigMergeCand – numCombMergeCand). When numZeroMergeCand is greater than 0, m ranges from 0 to numZeroMergeCand – 1, inclusive.
9. The following assignments are made with N being the candidate at position merge_idx[xOrigP][yOrigP] in the merging candidate list mergeCandList (N = mergeCandList[merge_idx[xOrigP][yOrigP]]) and X being replaced by 0 or 1:

$$\text{refIdxLX} = \text{refIdxLXN} \quad (8-120)$$

$$\text{predFlagLX} = \text{predFlagLXN} \quad (8-121)$$

- If use_integer_mv_flag is equal to 0 and the reference picture is not the current picture, the following applies:

$$\text{mvLX}[0] = \text{mvLXN}[0] \quad (8-122)$$

$$\text{mvLX}[1] = \text{mvLXN}[1] \quad (8-123)$$

- Otherwise (use_integer_mv_flag is equal to 1 or the reference picture is the current picture), the following applies:

$$\text{mvLX}[0] = (\text{mvLXN}[0] \gg 2) \ll 2 \quad (8-124)$$

$$\text{mvLX}[1] = (\text{mvLXN}[1] \gg 2) \ll 2 \quad (8-125)$$

10. When predFlagL0 is equal to 1 and predFlagL1 is equal to 1 and (nOrigPbW + nOrigPbH) is equal to 12, the following applies:

$$\text{refIdxL1} = -1 \quad (8-126)$$

$$\text{predFlagL1} = 0 \quad (8-127)$$

8.5.3.2.3 Derivation process for spatial merging candidates

Inputs to this process are:

- a luma location (xCb, yCb) of the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a variable nCbS specifying the size of the current luma coding block,

- a luma location (x_{Pb} , y_{Pb}) specifying the top-left sample of the current luma prediction block relative to the top-left luma sample of the current picture,
- two variables n_{PbW} and n_{PbH} specifying the width and the height of the luma prediction block,
- a variable $partIdx$ specifying the index of the current prediction unit within the current coding unit.

Outputs of this process are as follows, with X being 0 or 1:

- the availability flags $availableFlagA_0$, $availableFlagA_1$, $availableFlagB_0$, $availableFlagB_1$ and $availableFlagB_2$ of the neighbouring prediction units,
- the reference indices $refIdxLXA_0$, $refIdxLXA_1$, $refIdxLXB_0$, $refIdxLXB_1$ and $refIdxLXB_2$ of the neighbouring prediction units,
- the prediction list utilization flags $predFlagLXA_0$, $predFlagLXA_1$, $predFlagLXB_0$, $predFlagLXB_1$ and $predFlagLXB_2$ of the neighbouring prediction units,
- the motion vectors $mvLXA_0$, $mvLXA_1$, $mvLXB_0$, $mvLXB_1$ and $mvLXB_2$ of the neighbouring prediction units.

For the derivation of $availableFlagA_1$, $refIdxLXA_1$, $predFlagLXA_1$ and $mvLXA_1$ the following applies:

- The luma location (x_{NbA_1} , y_{NbA_1}) inside the neighbouring luma coding block is set equal to ($x_{Pb} - 1$, $y_{Pb} + n_{PbH} - 1$).
- The availability derivation process for a prediction block as specified in clause 6.4.2 is invoked with the luma location (x_{Cb} , y_{Cb}), the current luma coding block size n_{CbS} , the luma prediction block location (x_{Pb} , y_{Pb}), the luma prediction block width n_{PbW} , the luma prediction block height n_{PbH} , the luma location (x_{NbA_1} , y_{NbA_1}) and the partition index $partIdx$ as inputs, and the output is assigned to the prediction block availability flag $availableA_1$.
- When one or more of the following conditions are true, $availableA_1$ is set equal to FALSE:
 - $x_{Pb} \gg \text{Log2ParMrgLevel}$ is equal to $x_{NbA_1} \gg \text{Log2ParMrgLevel}$ and $y_{Pb} \gg \text{Log2ParMrgLevel}$ is equal to $y_{NbA_1} \gg \text{Log2ParMrgLevel}$.
 - $PartMode$ of the current prediction unit is equal to $PART_Nx2N$, $PART_nLx2N$ or $PART_nRx2N$ and $partIdx$ is equal to 1.
- The variables $availableFlagA_1$, $refIdxLXA_1$, $predFlagLXA_1$ and $mvLXA_1$ are derived as follows:
 - If $availableA_1$ is equal to FALSE, $availableFlagA_1$ is set equal to 0, both components of $mvLXA_1$ are set equal to 0, $refIdxLXA_1$ is set equal to -1 and $predFlagLXA_1$ is set equal to 0, with X being 0 or 1.
 - Otherwise, $availableFlagA_1$ is set equal to 1 and the following assignments are made:

$$mvLXA_1 = MvLX[x_{NbA_1}][y_{NbA_1}] \quad (8-128)$$

$$refIdxLXA_1 = RefIdxLX[x_{NbA_1}][y_{NbA_1}] \quad (8-129)$$

$$predFlagLXA_1 = PredFlagLX[x_{NbA_1}][y_{NbA_1}] \quad (8-130)$$

For the derivation of $availableFlagB_1$, $refIdxLXB_1$, $predFlagLXB_1$ and $mvLXB_1$ the following applies:

- The luma location (x_{NbB_1} , y_{NbB_1}) inside the neighbouring luma coding block is set equal to ($x_{Pb} + n_{PbW} - 1$, $y_{Pb} - 1$).
- The availability derivation process for a prediction block as specified in clause 6.4.2 is invoked with the luma location (x_{Cb} , y_{Cb}), the current luma coding block size n_{CbS} , the luma prediction block location (x_{Pb} , y_{Pb}), the luma prediction block width n_{PbW} , the luma prediction block height n_{PbH} , the luma location (x_{NbB_1} , y_{NbB_1}) and the partition index $partIdx$ as inputs, and the output is assigned to the prediction block availability flag $availableB_1$.
- When one or more of the following conditions are true, $availableB_1$ is set equal to FALSE:
 - $x_{Pb} \gg \text{Log2ParMrgLevel}$ is equal to $x_{NbB_1} \gg \text{Log2ParMrgLevel}$ and $y_{Pb} \gg \text{Log2ParMrgLevel}$ is equal to $y_{NbB_1} \gg \text{Log2ParMrgLevel}$.
 - $PartMode$ of the current prediction unit is equal to $PART_2NxN$, $PART_2NxN_U$ or $PART_2NxN_D$ and $partIdx$ is equal to 1.
- The variables $availableFlagB_1$, $refIdxLXB_1$, $predFlagLXB_1$ and $mvLXB_1$ are derived as follows:

- If one or more of the following conditions are true, availableFlagB₁ is set equal to 0, both components of mvLXB₁ are set equal to 0, refIdxLXB₁ is set equal to –1 and predFlagLXB₁ is set equal to 0, with X being 0 or 1:
 - availableB₁ is equal to FALSE.
 - availableA₁ is equal to TRUE and the prediction units covering the luma locations (xNbA₁, yNbA₁) and (xNbB₁, yNbB₁) have the same motion vectors and the same reference indices.
- Otherwise, availableFlagB₁ is set equal to 1 and the following assignments are made:

$$mvLXB_1 = MvLX[xNbB_1][yNbB_1] \quad (8-131)$$

$$refIdxLXB_1 = RefIdxLX[xNbB_1][yNbB_1] \quad (8-132)$$

$$predFlagLXB_1 = PredFlagLX[xNbB_1][yNbB_1] \quad (8-133)$$

For the derivation of availableFlagB₀, refIdxLXB₀, predFlagLXB₀ and mvLXB₀ the following applies:

- The luma location (xNbB₀, yNbB₀) inside the neighbouring luma coding block is set equal to (xPb + nPbW, yPb – 1).
- The availability derivation process for a prediction block as specified in clause 6.4.2 is invoked with the luma location (xCb, yCb), the current luma coding block size nCbS, the luma prediction block location (xPb, yPb), the luma prediction block width nPbW, the luma prediction block height nPbH, the luma location (xNbB₀, yNbB₀) and the partition index partIdx as inputs, and the output is assigned to the prediction block availability flag availableB₀.
- When xPb >> Log2ParMrgLevel is equal to xNbB₀ >> Log2ParMrgLevel and yPb >> Log2ParMrgLevel is equal to yNbB₀ >> Log2ParMrgLevel, availableB₀ is set equal to FALSE.
- The variables availableFlagB₀, refIdxLXB₀, predFlagLXB₀ and mvLXB₀ are derived as follows:
 - If one or more of the following conditions are true, availableFlagB₀ is set equal to 0, both components of mvLXB₀ are set equal to 0, refIdxLXB₀ is set equal to –1 and predFlagLXB₀ is set equal to 0, with X being 0 or 1:
 - availableB₀ is equal to FALSE.
 - availableB₁ is equal to TRUE and the prediction units covering the luma locations (xNbB₁, yNbB₁) and (xNbB₀, yNbB₀) have the same motion vectors and the same reference indices.
 - Otherwise, availableFlagB₀ is set equal to 1 and the following assignments are made:

$$mvLXB_0 = MvLX[xNbB_0][yNbB_0] \quad (8-134)$$

$$refIdxLXB_0 = RefIdxLX[xNbB_0][yNbB_0] \quad (8-135)$$

$$predFlagLXB_0 = PredFlagLX[xNbB_0][yNbB_0] \quad (8-136)$$

For the derivation of availableFlagA₀, refIdxLXA₀, predFlagLXA₀ and mvLXA₀ the following applies:

- The luma location (xNbA₀, yNbA₀) inside the neighbouring luma coding block is set equal to (xPb – 1, yPb + nPbH).
- The availability derivation process for a prediction block as specified in clause 6.4.2 is invoked with the luma location (xCb, yCb), the current luma coding block size nCbS, the luma prediction block location (xPb, yPb), the luma prediction block width nPbW, the luma prediction block height nPbH, the luma location (xNbA₀, yNbA₀) and the partition index partIdx as inputs, and the output is assigned to the prediction block availability flag availableA₀.
- When xPb >> Log2ParMrgLevel is equal to xNbA₀ >> Log2ParMrgLevel and yPb >> Log2ParMrgLevel is equal to yA₀ >> Log2ParMrgLevel, availableA₀ is set equal to FALSE.
- The variables availableFlagA₀, refIdxLXA₀, predFlagLXA₀ and mvLXA₀ are derived as follows:
 - If one or more of the following conditions are true, availableFlagA₀ is set equal to 0, both components of mvLXA₀ are set equal to 0, refIdxLXA₀ is set equal to –1 and predFlagLXA₀ is set equal to 0, with X being 0 or 1:
 - availableA₀ is equal to FALSE.

- availableA₁ is equal to TRUE and the prediction units covering the luma locations (xNbA₁, yNbA₁) and (xNbA₀, yNbA₀) have the same motion vectors and the same reference indices.
- Otherwise, availableFlagA₀ is set equal to 1 and the following assignments are made:

$$mvLXA_0 = MvLX[xNbA_0][yNbA_0] \quad (8-137)$$

$$refIdxLXA_0 = RefIdxLX[xNbA_0][yNbA_0] \quad (8-138)$$

$$predFlagLXA_0 = PredFlagLX[xNbA_0][yNbA_0] \quad (8-139)$$

For the derivation of availableFlagB₂, refIdxLXB₂, predFlagLXB₂ and mvLXB₂ the following applies:

- The luma location (xNbB₂, yNbB₂) inside the neighbouring luma coding block is set equal to (xPb – 1, yPb – 1).
- The availability derivation process for a prediction block as specified in clause 6.4.2 is invoked with the luma location (xCb, yCb), the current luma coding block size nCbS, the luma prediction block location (xPb, yPb), the luma prediction block width nPbW, the luma prediction block height nPbH, the luma location (xNbB₂, yNbB₂) and the partition index partIdx as inputs, and the output is assigned to the prediction block availability flag availableB₂.
- When xPb >> Log2ParMrgLevel is equal to xNbB₂ >> Log2ParMrgLevel and yPb >> Log2ParMrgLevel is equal to yNbB₂ >> Log2ParMrgLevel, availableB₂ is set equal to FALSE.
- The variables availableFlagB₂, refIdxLXB₂, predFlagLXB₂ and mvLXB₂ are derived as follows:
 - If one or more of the following conditions are true, availableFlagB₂ is set equal to 0, both components of mvLXB₂ are set equal to 0, refIdxLXB₂ is set equal to –1 and predFlagLXB₂ is set equal to 0, with X being 0 or 1:
 - availableB₂ is equal to FALSE.
 - availableA₁ is equal to TRUE and prediction units covering the luma locations (xNbA₁, yNbA₁) and (xNbB₂, yNbB₂) have the same motion vectors and the same reference indices.
 - availableB₁ is equal to TRUE and the prediction units covering the luma locations (xNbB₁, yNbB₁) and (xNbB₂, yNbB₂) have the same motion vectors and the same reference indices.
 - availableFlagA₀ + availableFlagA₁ + availableFlagB₀ + availableFlagB₁ is equal to 4.
 - Otherwise, availableFlagB₂ is set equal to 1 and the following assignments are made:

$$mvLXB_2 = MvLX[xNbB_2][yNbB_2] \quad (8-140)$$

$$refIdxLXB_2 = RefIdxLX[xNbB_2][yNbB_2] \quad (8-141)$$

$$predFlagLXB_2 = PredFlagLX[xNbB_2][yNbB_2] \quad (8-142)$$

8.5.3.2.4 Derivation process for combined bi-predictive merging candidates

Inputs to this process are:

- a merging candidate list mergeCandList,
- the reference indices refIdxL0N and refIdxL1N of every candidate N in mergeCandList,
- the prediction list utilization flags predFlagL0N and predFlagL1N of every candidate N in mergeCandList,
- the motion vectors mvL0N and mvL1N of every candidate N in mergeCandList,
- the number of elements numCurrMergeCand within mergeCandList,
- the number of elements numOrigMergeCand within the mergeCandList after the spatial and temporal merge candidate derivation process.

Outputs of this process are:

- the merging candidate list mergeCandList,
- the number of elements numCurrMergeCand within mergeCandList,
- the reference indices refIdxL0combCand_k and refIdxL1combCand_k of every new candidate combCand_k added into mergeCandList during the invocation of this process,

- the prediction list utilization flags $\text{predFlagL0combCand}_k$ and $\text{predFlagL1combCand}_k$ of every new candidate combCand_k added into mergeCandList during the invocation of this process,
- the motion vectors mvL0combCand_k and mvL1combCand_k of every new candidate combCand_k added into mergeCandList during the invocation of this process.

When numOrigMergeCand is greater than 1 and less than MaxNumMergeCand , the variable numInputMergeCand is set equal to numCurrMergeCand , the variable combIdx is set equal to 0, the variable combStop is set equal to FALSE and the following ordered steps are repeated until combStop is equal to TRUE:

1. The variables l0CandIdx and l1CandIdx are derived using combIdx as specified in Table 8-7.
2. The following assignments are made, with l0Cand being the candidate at position l0CandIdx and l1Cand being the candidate at position l1CandIdx in the merging candidate list mergeCandList :
 - $\text{l0Cand} = \text{mergeCandList}[\text{l0CandIdx}]$
 - $\text{l1Cand} = \text{mergeCandList}[\text{l1CandIdx}]$
3. When all of the following conditions are true:
 - $\text{predFlagL0l0Cand} == 1$
 - $\text{predFlagL1l1Cand} == 1$
 - $(\text{DiffPicOrderCnt}(\text{RefPicList0}[\text{refIdxL0l0Cand}], \text{RefPicList1}[\text{refIdxL1l1Cand}]) \neq 0) \quad || \quad (\text{mvL0l0Cand} \neq \text{mvL1l1Cand})$

the candidate combCand_k with k equal to $(\text{numCurrMergeCand} - \text{numInputMergeCand})$ is added at the end of mergeCandList , i.e., $\text{mergeCandList}[\text{numCurrMergeCand}]$ is set equal to combCand_k , and the reference indices, the prediction list utilization flags and the motion vectors of combCand_k are derived as follows and numCurrMergeCand is incremented by 1:

$$\text{refIdxL0combCand}_k = \text{refIdxL0l0Cand} \quad (8-143)$$

$$\text{refIdxL1combCand}_k = \text{refIdxL1l1Cand} \quad (8-144)$$

$$\text{predFlagL0combCand}_k = 1 \quad (8-145)$$

$$\text{predFlagL1combCand}_k = 1 \quad (8-146)$$

$$\text{mvL0combCand}_k[0] = \text{mvL0l0Cand}[0] \quad (8-147)$$

$$\text{mvL0combCand}_k[1] = \text{mvL0l0Cand}[1] \quad (8-148)$$

$$\text{mvL1combCand}_k[0] = \text{mvL1l1Cand}[0] \quad (8-149)$$

$$\text{mvL1combCand}_k[1] = \text{mvL1l1Cand}[1] \quad (8-150)$$

$$\text{numCurrMergeCand} = \text{numCurrMergeCand} + 1 \quad (8-151)$$

4. The variable combIdx is incremented by 1.
5. When combIdx is equal to $(\text{numOrigMergeCand} * (\text{numOrigMergeCand} - 1))$ or numCurrMergeCand is equal to MaxNumMergeCand , combStop is set equal to TRUE.

Table 8-7 – Specification of l0CandIdx and l1CandIdx

combIdx	0	1	2	3	4	5	6	7	8	9	10	11
l0CandIdx	0	1	0	2	1	2	0	3	1	3	2	3
l1CandIdx	1	0	2	0	2	1	3	0	3	1	3	2

8.5.3.2.5 Derivation process for zero motion vector merging candidates

Inputs to this process are:

- a merging candidate list mergeCandList,
- the reference indices refIdxL0N and refIdxL1N of every candidate N in mergeCandList,
- the prediction list utilization flags predFlagL0N and predFlagL1N of every candidate N in mergeCandList,
- the motion vectors mvL0N and mvL1N of every candidate N in mergeCandList,
- the number of elements numCurrMergeCand within mergeCandList.

Outputs of this process are:

- the merging candidate list mergeCandList,
- the number of elements numCurrMergeCand within mergeCandList,
- the reference indices refIdxL0zeroCand_m and refIdxL1zeroCand_m of every new candidate zeroCand_m added into mergeCandList during the invocation of this process,
- the prediction list utilization flags predFlagL0zeroCand_m and predFlagL1zeroCand_m of every new candidate zeroCand_m added into mergeCandList during the invocation of this process,
- the motion vectors mvL0zeroCand_m and mvL1zeroCand_m of every new candidate zeroCand_m added into mergeCandList during the invocation of this process.

The variable numRefIdx is derived as follows:

- If slice_type is equal to P, numRefIdx is set equal to num_ref_idx_l0_active_minus1 + 1.
- Otherwise (slice_type is equal to B), numRefIdx is set equal to Min(num_ref_idx_l0_active_minus1 + 1, num_ref_idx_l1_active_minus1 + 1).

When numCurrMergeCand is less than MaxNumMergeCand, the variable numInputMergeCand is set equal to numCurrMergeCand, the variable zeroIdx is set equal to 0 and the following ordered steps are repeated until numCurrMergeCand is equal to MaxNumMergeCand:

1. For the derivation of the reference indices, the prediction list utilization flags and the motion vectors of the zero motion vector merging candidate, the following applies:
 - If slice_type is equal to P, the candidate zeroCand_m with m equal to (numCurrMergeCand – numInputMergeCand) is added at the end of mergeCandList, i.e., mergeCandList[numCurrMergeCand] is set equal to zeroCand_m, and the reference indices, the prediction list utilization flags and the motion vectors of zeroCand_m are derived as follows and numCurrMergeCand is incremented by 1:

$$\text{refIdxL0zeroCand}_m = (\text{zeroIdx} < \text{numRefIdx}) ? \text{zeroIdx} : 0 \quad (8-152)$$

$$\text{refIdxL1zeroCand}_m = -1 \quad (8-153)$$

$$\text{predFlagL0zeroCand}_m = 1 \quad (8-154)$$

$$\text{predFlagL1zeroCand}_m = 0 \quad (8-155)$$

$$\text{mvL0zeroCand}_m[0] = 0 \quad (8-156)$$

$$\text{mvL0zeroCand}_m[1] = 0 \quad (8-157)$$

$$\text{mvL1zeroCand}_m[0] = 0 \quad (8-158)$$

$$\text{mvL1zeroCand}_m[1] = 0 \quad (8-159)$$

$$\text{numCurrMergeCand} = \text{numCurrMergeCand} + 1 \quad (8-160)$$

- Otherwise (slice_type is equal to B), the candidate zeroCand_m with m equal to (numCurrMergeCand – numInputMergeCand) is added at the end of mergeCandList, i.e.,

mergeCandList[numCurrMergeCand] is set equal to zeroCand_m, and the reference indices, the prediction list utilization flags and the motion vectors of zeroCand_m are derived as follows and numCurrMergeCand is incremented by 1:

$$\text{refIdxL0zeroCand}_m = (\text{zeroIdx} < \text{numRefIdx}) ? \text{zeroIdx} : 0 \quad (8-161)$$

$$\text{refIdxL1zeroCand}_m = (\text{zeroIdx} < \text{numRefIdx}) ? \text{zeroIdx} : 0 \quad (8-162)$$

$$\text{predFlagL0zeroCand}_m = 1 \quad (8-163)$$

$$\text{predFlagL1zeroCand}_m = 1 \quad (8-164)$$

$$\text{mvL0zeroCand}_m[0] = 0 \quad (8-165)$$

$$\text{mvL0zeroCand}_m[1] = 0 \quad (8-166)$$

$$\text{mvL1zeroCand}_m[0] = 0 \quad (8-167)$$

$$\text{mvL1zeroCand}_m[1] = 0 \quad (8-168)$$

$$\text{numCurrMergeCand} = \text{numCurrMergeCand} + 1 \quad (8-169)$$

2. The variable zeroIdx is incremented by 1.

8.5.3.2.6 Derivation process for luma motion vector prediction

Inputs to this process are:

- a luma location (xCb, yCb) of the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a variable nCbS specifying the size of the current luma coding block,
- a luma location (xPb, yPb) specifying the top-left sample of the current luma prediction block relative to the top-left luma sample of the current picture,
- two variables nPbW and nPbH specifying the width and the height of the luma prediction block,
- the reference index of the current prediction unit partition refIdxLX, with X being 0 or 1,
- a variable partIdx specifying the index of the current prediction unit within the current coding unit.

Output of this process is the prediction mvpLX of the motion vector mvLX, with X being 0 or 1.

The motion vector predictor mvpLX is derived in the following ordered steps:

1. The derivation process for motion vector predictor candidates from neighbouring prediction unit partitions in clause 8.5.3.2.7 is invoked with the luma coding block location (xCb, yCb), the coding block size nCbS, the luma prediction block location (xPb, yPb), the luma prediction block width nPbW, the luma prediction block height nPbH, refIdxLX, with X being 0 or 1 and the partition index partIdx as inputs, and the availability flags availableFlagLXN and the motion vectors mvLXN, with N being replaced by A or B, as output.
2. If both availableFlagLXA and availableFlagLXB are equal to 1 and mvLXA is not equal to mvLXB, availableFlagLXCol is set equal to 0. Otherwise, the derivation process for temporal luma motion vector prediction in clause 8.5.3.2.8 is invoked with luma prediction block location (xPb, yPb), the luma prediction block width nPbW, the luma prediction block height nPbH and refIdxLX, with X being 0 or 1 as inputs, and with the output being the availability flag availableFlagLXCol and the temporal motion vector predictor mvLXCol.
3. The motion vector predictor candidate list, mvpListLX, is constructed as follows:

```

i = 0
if( availableFlagLXA ) {
    mvpListLX[ i++ ] = mvLXA
    if( availableFlagLXB && ( mvLXA != mvLXB ) )
        mvpListLX[ i++ ] = mvLXB
} else if( availableFlagLXB )
    mvpListLX[ i++ ] = mvLXB

```

(8-170)

```

if( i < 2 && availableFlagLXCol )
   .mvpListLX[ i++ ] = mvLXCol
while( i < 2 ) {
   .mvpListLX[ i ][ 0 ] = 0
   .mvpListLX[ i ][ 1 ] = 0
    i++
}

```

4. The motion vector of $\text{mvListLX}[\text{mv_lX_flag}[\text{xPb}][\text{yPb}]]$ is assigned to mvLX .

8.5.3.2.7 Derivation process for motion vector predictor candidates

Inputs to this process are:

- a luma location (xCb, yCb) of the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a variable nCbS specifying the size of the current luma coding block,
- a luma location (xPb, yPb) specifying the top-left sample of the current luma prediction block relative to the top-left luma sample of the current picture,
- two variables nPbW and nPbH specifying the width and the height of the luma prediction block,
- the reference index of the current prediction unit partition refIdxLX , with X being 0 or 1,
- a variable partIdx specifying the index of the current prediction unit within the current coding unit.

Outputs of this process are (with N being replaced by A or B):

- the motion vectors mvLXN of the neighbouring prediction units,
- the availability flags availableFlagLXN of the neighbouring prediction units.

Figure 8-3 provides an overview of spatial motion vector neighbours.

Figure 8-3 – Spatial motion vector neighbours (informative)

The variable currPb specifies the current luma prediction block at luma location (xPb, yPb) and the variable currPic specifies the current picture.

The variable isScaledFlagLX , with X being 0 or 1, is set equal to 0.

The motion vector mvLXA and the availability flag availableFlagLXA are derived in the following ordered steps:

1. The sample location ($\text{xNbA}_0, \text{yNbA}_0$) is set equal to ($\text{xPb} - 1, \text{yPb} + \text{nPbH}$) and the sample location ($\text{xNbA}_1, \text{yNbA}_1$) is set equal to ($\text{xNbA}_0, \text{yNbA}_0 - 1$).
2. The availability flag availableFlagLXA is set equal to 0 and both components of mvLXA are set equal to 0.
3. The availability derivation process for a prediction block as specified in clause 6.4.2 is invoked with the luma location (xCb, yCb), the current luma coding block size nCbS , the luma prediction block location (xPb, yPb), the luma prediction block width nPbW , the luma prediction block height nPbH , the luma location (xNbY, yNbY) set equal to ($\text{xNbA}_0, \text{yNbA}_0$) and the partition index partIdx as inputs, and the output is assigned to the prediction block availability flag availableA_0 .
4. The availability derivation process for a prediction block as specified in clause 6.4.2 is invoked with the luma location (xCb, yCb), the current luma coding block size nCbS , the luma prediction block location (xPb, yPb),

the luma prediction block width nPbW, the luma prediction block height nPbH, the luma location (xNbY, yNbY) set equal to (xNbA₁, yNbA₁) and the partition index partIdx as inputs, and the output is assigned to the prediction block availability flag availableA₁.

5. When availableA₀ or availableA₁ is equal to TRUE, the variable isScaledFlagLX is set equal to 1.

6. The following applies for (xNbA_k, yNbA_k) from (xNbA₀, yNbA₀) to (xNbA₁, yNbA₁):

– When availableA_k is equal to TRUE and availableFlagLXA is equal to 0, the following applies:

– If PredFlagLX[xNbA_k][yNbA_k] is equal to 1 and DiffPicOrderCnt(RefPicListX[RefIdxLX[xNbA_k][yNbA_k]], RefPicListX[refIdxLX]) is equal to 0, availableFlagLXA is set equal to 1 and the following applies:

$$mvLXA = MvLX[xNbA_k][yNbA_k] \quad (8-171)$$

– Otherwise, when PredFlagLY[xNbA_k][yNbA_k] (with Y = !X) is equal to 1 and DiffPicOrderCnt(RefPicListY[RefIdxLY[xNbA_k][yNbA_k]], RefPicListX[refIdxLX]) is equal to 0, availableFlagLXA is set equal to 1 and the following applies:

$$mvLXA = MvLY[xNbA_k][yNbA_k] \quad (8-172)$$

7. When availableFlagLXA is equal to 0, the following applies for (xNbA_k, yNbA_k) from (xNbA₀, yNbA₀) to (xNbA₁, yNbA₁) or until availableFlagLXA is equal to 1:

– When availableA_k is equal to TRUE and availableFlagLXA is equal to 0, the following applies:

– If PredFlagLX[xNbA_k][yNbA_k] is equal to 1 and LongTermRefPic(currPic, currPb, refIdxLX, RefPicListX) is equal to LongTermRefPic(currPic, currPb, RefIdxLX[xNbA_k][yNbA_k], RefPicListX), availableFlagLXA is set equal to 1 and the following assignments are made:

$$mvLXA = MvLX[xNbA_k][yNbA_k] \quad (8-173)$$

$$refIdxA = RefIdxLX[xNbA_k][yNbA_k] \quad (8-174)$$

$$refPicListA = RefPicListX \quad (8-175)$$

– Otherwise, when PredFlagLY[xNbA_k][yNbA_k] (with Y = !X) is equal to 1 and LongTermRefPic(currPic, currPb, refIdxLX, RefPicListX) is equal to LongTermRefPic(currPic, currPb, RefIdxLY[xNbA_k][yNbA_k], RefPicListY), availableFlagLXA is set equal to 1 and the following assignments are made:

$$mvLXA = MvLY[xNbA_k][yNbA_k] \quad (8-176)$$

$$refIdxA = RefIdxLY[xNbA_k][yNbA_k] \quad (8-177)$$

$$refPicListA = RefPicListY \quad (8-178)$$

– When availableFlagLXA is equal to 1, DiffPicOrderCnt(refPicListA[refIdxA], RefPicListX[refIdxLX]) is not equal to 0, and both refPicListA[refIdxA] and RefPicListX[refIdxLX] are short-term reference pictures, mvLXA is derived as follows:

$$tx = (16384 + (Abs(td) >> 1)) / td \quad (8-179)$$

$$distScaleFactor = Clip3(-4096, 4095, (tb * tx + 32) >> 6) \quad (8-180)$$

$$mvLXA = Clip3(-32768, 32767, Sign(distScaleFactor * mvLXA) * ((Abs(distScaleFactor * mvLXA) + 127) >> 8)) \quad (8-181)$$

where td and tb are derived as follows:

$$td = Clip3(-128, 127, DiffPicOrderCnt(currPic, refPicListA[refIdxA])) \quad (8-182)$$

$$tb = Clip3(-128, 127, DiffPicOrderCnt(currPic, RefPicListX[refIdxLX])) \quad (8-183)$$

The motion vector mvLXB and the availability flag availableFlagLXB are derived in the following ordered steps:

1. The sample locations (xNbB₀, yNbB₀), (xNbB₁, yNbB₁) and (xNbB₂, yNbB₂) are set equal to (xPb + nPbW, yPb - 1), (xPb + nPbW - 1, yPb - 1) and (xPb - 1, yPb - 1), respectively.
2. The availability flag availableFlagLXB is set equal to 0 and the both components of mvLXB are set equal to 0.
3. The following applies for (xNbB_k, yNbB_k) from (xNbB₀, yNbB₀) to (xNbB₂, yNbB₂):
 - The availability derivation process for a prediction block as specified in clause 6.4.2 is invoked with the luma location (xCb, yCb), the current luma coding block size nCbS, the luma prediction block location (xPb, yPb), the luma prediction block width nPbW, the luma prediction block height nPbH, the luma location (xNbY, yNbY) set equal to (xNbB_k, yNbB_k) and the partition index partIdx as inputs, and the output is assigned to the prediction block availability flag availableB_k.
 - When availableB_k is equal to TRUE and availableFlagLXB is equal to 0, the following applies:
 - If PredFlagLX[xNbB_k][yNbB_k] is equal to 1, and DiffPicOrderCnt(RefPicListX[RefIdxLX[xNbB_k][yNbB_k]], RefPicListX[refIdxLX]) is equal to 0, availableFlagLXB is set equal to 1 and the following assignment are made:

$$mvLXB = MvLX[xNbB_k][yNbB_k] \quad (8-184)$$

- Otherwise, when PredFlagLY[xNbB_k][yNbB_k] (with Y = !X) is equal to 1 and DiffPicOrderCnt(RefPicListY[RefIdxLY[xNbB_k][yNbB_k]], RefPicListX[refIdxLX]) is equal to 0, availableFlagLXB is set equal to 1 and the following assignment is made:

$$mvLXB = MvLY[xNbB_k][yNbB_k] \quad (8-185)$$

4. When isScaledFlagLX is equal to 0 and availableFlagLXB is equal to 1, availableFlagLXA is set equal to 1 and the following applies:

$$mvLXA = mvLXB \quad (8-186)$$

5. When isScaledFlagLX is equal to 0, availableFlagLXB is set equal to 0 and the following applies for (xNbB_k, yNbB_k) from (xNbB₀, yNbB₀) to (xNbB₂, yNbB₂) or until availableFlagLXB is equal to 1:

- The availability derivation process for a prediction block as specified in clause 6.4.2 is invoked with the luma location (xCb, yCb), the current luma coding block size nCbS, the luma location (xPb, yPb), the luma prediction block width nPbW, the luma prediction block height nPbH, the luma location (xNbY, yNbY) set equal to (xNbB_k, yNbB_k) and the partition index partIdx as inputs, and the output is assigned to the prediction block availability flag availableB_k.
- When availableB_k is equal to TRUE and availableFlagLXB is equal to 0, the following applies:
 - If PredFlagLX[xNbB_k][yNbB_k] is equal to 1 and LongTermRefPic(currPic, currPb, refIdxLX, RefPicListX) is equal to LongTermRefPic(currPic, currPb, RefIdxLX[xNbB_k][yNbB_k], RefPicListX), availableFlagLXB is set equal to 1 and the following assignments are made:

$$mvLXB = MvLX[xNbB_k][yNbB_k] \quad (8-187)$$

$$refIdxB = RefIdxLX[xNbB_k][yNbB_k] \quad (8-188)$$

$$refPicListB = RefPicListX \quad (8-189)$$

- Otherwise, when PredFlagLY[xNbB_k][yNbB_k] (with Y = !X) is equal to 1 and LongTermRefPic(currPic, currPb, refIdxLX, RefPicListX) is equal to LongTermRefPic(currPic, currPb, RefIdxLY[xNbB_k][yNbB_k], RefPicListY), availableFlagLXB is set equal to 1 and the following assignments are made:

$$mvLXB = MvLY[xNbB_k][yNbB_k] \quad (8-190)$$

$$refIdxB = RefIdxLY[xNbB_k][yNbB_k] \quad (8-191)$$

$$refPicListB = RefPicListY \quad (8-192)$$

- When availableFlagLXB is equal to 1, DiffPicOrderCnt(refPicListB[refIdxB], RefPicListX[refIdxLX]) is not equal to 0 and both refPicListB[refIdxB] and RefPicListX[refIdxLX] are short-term reference pictures, mvLXB is derived as follows:

$$tx = (16384 + (Abs(td) >> 1)) / td \quad (8-193)$$

$$distScaleFactor = Clip3(-4096, 4095, (tb * tx + 32) >> 6) \quad (8-194)$$

$$mvLXB = Clip3(-32768, 32767, Sign(distScaleFactor * mvLXB) * ((Abs(distScaleFactor * mvLXB) + 127) >> 8)) \quad (8-195)$$

where td and tb are derived as follows:

$$td = Clip3(-128, 127, DiffPicOrderCnt(currPic, refPicListB[refIdxB])) \quad (8-196)$$

$$tb = Clip3(-128, 127, DiffPicOrderCnt(currPic, RefPicListX[refIdxLX])) \quad (8-197)$$

8.5.3.2.8 Derivation process for temporal luma motion vector prediction

Inputs to this process are:

- a luma location (xPb, yPb) specifying the top-left sample of the current luma prediction block relative to the top-left luma sample of the current picture,
- two variables nPbW and nPbH specifying the width and the height of the luma prediction block,
- a reference index refIdxLX, with X being 0 or 1.

Outputs of this process are:

- the motion vector prediction mvLXCol,
- the availability flag availableFlagLXCol.

The variable currPb specifies the current luma prediction block at luma location (xPb, yPb).

The variables mvLXCol and availableFlagLXCol are derived as follows:

- If slice_temporal_mvp_enabled_flag is equal to 0, both components of mvLXCol are set equal to 0 and availableFlagLXCol is set equal to 0.
- Otherwise (slice_temporal_mvp_enabled_flag is equal to 1), the following ordered steps apply:

1. The bottom right collocated motion vector is derived as follows:

$$xColBr = xPb + nPbW \quad (8-198)$$

$$yColBr = yPb + nPbH \quad (8-199)$$

- If $yPb >> CtbLog2SizeY$ is equal to $yColBr >> CtbLog2SizeY$, $yColBr$ is less than $pic_height_in_luma_samples$ and $xColBr$ is less than $pic_width_in_luma_samples$, the following applies:
 - The variable colPb specifies the luma prediction block covering the modified location given by $((xColBr >> 4) << 4, (yColBr >> 4) << 4)$ inside the collocated picture specified by ColPic.
 - The luma location (xColPb, yColPb) is set equal to the top-left sample of the collocated luma prediction block specified by colPb relative to the top-left luma sample of the collocated picture specified by ColPic.
 - The derivation process for collocated motion vectors as specified in clause 8.5.3.2.9 is invoked with currPb, colPb, (xColPb, yColPb) and refIdxLX as inputs, and the output is assigned to mvLXCol and availableFlagLXCol.
 - Otherwise, both components of mvLXCol are set equal to 0 and availableFlagLXCol is set equal to 0.
- 2. When availableFlagLXCol is equal to 0, the central collocated motion vector is derived as follows:

$$xColCtr = xPb + (nPbW >> 1) \quad (8-200)$$

$$yColCtr = yPb + (nPbH \gg 1) \quad (8-201)$$

- The variable colPb specifies the luma prediction block covering the modified location given by $((xColCtr \gg 4) \ll 4, (yColCtr \gg 4) \ll 4)$ inside the collocated picture specified by ColPic.
- The luma location $(xColPb, yColPb)$ is set equal to the top-left sample of the collocated luma prediction block specified by colPb relative to the top-left luma sample of the collocated picture specified by ColPic.
- The derivation process for collocated motion vectors as specified in clause 8.5.3.2.9 is invoked with currPb, colPb, $(xColPb, yColPb)$ and refIdxLX as inputs, and the output is assigned to mvLXCol and availableFlagLXCol.

8.5.3.2.9 Derivation process for collocated motion vectors

Inputs to this process are:

- a variable currPb specifying the current prediction block,
- a variable colPb specifying the collocated prediction block inside the collocated picture specified by ColPic,
- a luma location $(xColPb, yColPb)$ specifying the top-left sample of the collocated luma prediction block specified by colPb relative to the top-left luma sample of the collocated picture specified by ColPic,
- a reference index refIdxLX, with X being 0 or 1.

Outputs of this process are:

- the motion vector prediction mvLXCol,
- the availability flag availableFlagLXCol.

The variable currPic specifies the current picture.

The arrays predFlagL0Col[x][y], mvL0Col[x][y] and refIdxL0Col[x][y] are set equal to PredFlagL0[x][y], MvL0[x][y] and RefIdxL0[x][y], respectively, of the collocated picture specified by ColPic, and the arrays predFlagL1Col[x][y], mvL1Col[x][y] and refIdxL1Col[x][y] are set equal to PredFlagL1[x][y], MvL1[x][y] and RefIdxL1[x][y], respectively, of the collocated picture specified by ColPic.

The variables mvLXCol and availableFlagLXCol are derived as follows:

- If colPb is coded in an intra prediction mode, both components of mvLXCol are set equal to 0 and availableFlagLXCol is set equal to 0.
- Otherwise, the motion vector mvCol, the reference index refIdxCol and the reference list identifier listCol are derived as follows:
 - If predFlagL0Col[xColPb][yColPb] is equal to 0, mvCol, refIdxCol and listCol are set equal to mvL1Col[xColPb][yColPb], refIdxL1Col[xColPb][yColPb] and L1, respectively.
 - Otherwise, if predFlagL0Col[xColPb][yColPb] is equal to 1 and predFlagL1Col[xColPb][yColPb] is equal to 0, mvCol, refIdxCol and listCol are set equal to mvL0Col[xColPb][yColPb], refIdxL0Col[xColPb][yColPb] and L0, respectively.
 - Otherwise (predFlagL0Col[xColPb][yColPb] is equal to 1 and predFlagL1Col[xColPb][yColPb] is equal to 1), the following assignments are made:
 - If NoBackwardPredFlag is equal to 1, mvCol, refIdxCol and listCol are set equal to mvLXCol[xColPb][yColPb], refIdxLXCol[xColPb][yColPb] and LX, respectively.
 - Otherwise, mvCol, refIdxCol and listCol are set equal to mvLNCOL[xColPb][yColPb], refIdxLNCOL[xColPb][yColPb] and LN, respectively, with N being the value of collocated_from_l0_flag.

And mvLXCol and availableFlagLXCol are derived as follows:

- If LongTermRefPic(currPic, currPb, refIdxLX, LX) is not equal to LongTermRefPic(ColPic, colPb, refIdxCol, listCol), both components of mvLXCol are set equal to 0 and availableFlagLXCol is set equal to 0.
- Otherwise, the variable availableFlagLXCol is set equal to 1, refPicListCol[refIdxCol] is set to be the picture with reference index refIdxCol in the reference picture list listCol of the slice containing prediction block colPb in the collocated picture specified by ColPic, and the following applies:

$$colPocDiff = DiffPicOrderCnt(ColPic, refPicListCol[refIdxCol]) \quad (8-202)$$

$$\text{currPocDiff} = \text{DiffPicOrderCnt}(\text{currPic}, \text{RefPicListX}[\text{refIdxLX}]) \quad (8-203)$$

- If $\text{RefPicListX}[\text{refIdxLX}]$ is a long-term reference picture, or colPocDiff is equal to currPocDiff , mvLXCol is derived as follows:

$$\text{mvLXCol} = \text{mvCol} \quad (8-204)$$

- Otherwise, mvLXCol is derived as a scaled version of the motion vector mvCol as follows:

$$\text{tx} = (16384 + (\text{Abs}(\text{td}) \gg 1)) / \text{td} \quad (8-205)$$

$$\text{distScaleFactor} = \text{Clip3}(-4096, 4095, (\text{tb} * \text{tx} + 32) \gg 6) \quad (8-206)$$

$$\text{mvLXCol} = \text{Clip3}(-32768, 32767, \text{Sign}(\text{distScaleFactor} * \text{mvCol}) * ((\text{Abs}(\text{distScaleFactor} * \text{mvCol}) + 127) \gg 8)) \quad (8-207)$$

where td and tb are derived as follows:

$$\text{td} = \text{Clip3}(-128, 127, \text{colPocDiff}) \quad (8-208)$$

$$\text{tb} = \text{Clip3}(-128, 127, \text{currPocDiff}) \quad (8-209)$$

8.5.3.2.10 Derivation process for chroma motion vectors

This process is invoked when ChromaArrayType is not equal to 0.

Input to this process is a luma motion vector mvLX .

Output of this process is a chroma motion vector mvCLX .

A chroma motion vector is derived from the corresponding luma motion vector.

For the derivation of the chroma motion vector mvCLX , the following applies:

$$\text{mvCLX}[0] = \text{mvLX}[0] * 2 / \text{SubWidthC} \quad (8-210)$$

$$\text{mvCLX}[1] = \text{mvLX}[1] * 2 / \text{SubHeightC} \quad (8-211)$$

8.5.3.3 Decoding process for inter prediction samples

8.5.3.3.1 General

Inputs to this process are:

- a luma location (xCb, yCb) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a luma location (xBl, yBl) specifying the top-left sample of the current luma prediction block relative to the top-left sample of the current luma coding block,
- a variable nCbS specifying the size of the current luma coding block,
- two variables nPbW and nPbH specifying the width and the height of the luma prediction block,
- the luma motion vectors mvL0 and mvL1 ,
- when ChromaArrayType is not equal to 0, the chroma motion vectors mvCL0 and mvCL1 ,
- the reference indices refIdxL0 and refIdxL1 ,
- the prediction list utilization flags, predFlagL0 , and predFlagL1 .

Outputs of this process are:

- an $(\text{nCbSL}) \times (\text{nCbSL})$ array predSamples_L of luma prediction samples, where nCbSL is derived as specified below,
- when ChromaArrayType is not equal to 0, an $(\text{nCbSw}_C) \times (\text{nCbSh}_C)$ array predSamples_{Cb} of chroma prediction samples for the component Cb , where nCbSw_C and nCbSh_C are derived as specified below,

- when ChromaArrayType is not equal to 0, an $(nCbSw_C) \times (nCbSh_C)$ array $predSamples_{Cr}$ of chroma prediction samples for the component Cr, where $nCbSw_C$ and $nCbSh_C$ are derived as specified below.

The variable $nCbS_L$ is set equal to $nCbS$. When ChromaArrayType is not equal to 0, the variable $nCbSw_C$ is set equal to $nCbS / SubWidthC$ and the variable $nCbSh_C$ is set equal to $nCbS / SubHeightC$.

Let $predSamplesL0_L$ and $predSamplesL1_L$ be $(nPbW) \times (nPbH)$ arrays of predicted luma sample values and, when ChromaArrayType is not equal to 0, $predSamplesL0_{Cb}$, $predSamplesL1_{Cb}$, $predSamplesL0_{Cr}$ and $predSamplesL1_{Cr}$ be $(nPbW / SubWidthC) \times (nPbH / SubHeightC)$ arrays of predicted chroma sample values.

For X being each of 0 and 1, when $predFlagLX$ is equal to 1, the following applies:

- The reference picture consisting of an ordered two-dimensional array $refPicLX_L$ of luma samples and, when ChromaArrayType is not equal to 0, two ordered two-dimensional arrays $refPicLX_{Cb}$ and $refPicLX_{Cr}$ of chroma samples is derived by invoking the process specified in clause 8.5.3.3.2 with $refIdxLX$ as input.
- The array $predSamplesLX_L$ and, when ChromaArrayType is not equal to 0, the arrays $predSamplesLX_{Cb}$ and $predSamplesLX_{Cr}$ are derived by invoking the fractional sample interpolation process specified in clause 8.5.3.3.3 with the luma locations (xCb, yCb) and (xBl, yBl) , the luma prediction block width $nPbW$, the luma prediction block height $nPbH$, the motion vectors $mvLX$ and, when ChromaArrayType is not equal to 0, $mvCLX$, and the reference arrays $refPicLX_L$, $refPicLX_{Cb}$, and $refPicLX_{Cr}$ as inputs.

The prediction samples inside the current luma prediction block, $predSamples_L[x_L + xBl][y_L + yBl]$ with $x_L = 0..nPbW - 1$ and $y_L = 0..nPbH - 1$, are derived by invoking the weighted sample prediction process specified in clause 8.5.3.3.4 with the prediction block width $nPbW$, the prediction block height $nPbH$ and the sample arrays $predSamplesL0_L$ and $predSamplesL1_L$, and the variables $predFlagL0$, $predFlagL1$, $refIdxL0$, $refIdxL1$ and $cIdx$ equal to 0 as inputs.

When ChromaArrayType is not equal to 0, the prediction samples inside the current chroma component Cb prediction block, $predSamples_{Cb}[x_C + xBl / SubWidthC][y_C + yBl / SubHeightC]$ with $x_C = 0..nPbW / SubWidthC - 1$ and $y_C = 0..nPbH / SubHeightC - 1$, are derived by invoking the weighted sample prediction process specified in clause 8.5.3.3.4 with the prediction block width $nPbW$ set equal to $nPbW / SubWidthC$, the prediction block height $nPbH$ set equal to $nPbH / SubHeightC$, the sample arrays $predSamplesL0_{Cb}$ and $predSamplesL1_{Cb}$, and the variables $predFlagL0$, $predFlagL1$, $refIdxL0$, $refIdxL1$ and $cIdx$ equal to 1 as inputs.

When ChromaArrayType is not equal to 0, the prediction samples inside the current chroma component Cr prediction block, $predSamples_{Cr}[x_C + xBl / SubWidthC][y_C + yBl / SubHeightC]$ with $x_C = 0..nPbW / SubWidthC - 1$ and $y_C = 0..nPbH / SubHeightC - 1$, are derived by invoking the weighted sample prediction process specified in clause 8.5.3.3.4 with the prediction block width $nPbW$ set equal to $nPbW / SubWidthC$, the prediction block height $nPbH$ set equal to $nPbH / SubHeightC$, the sample arrays $predSamplesL0_{Cr}$ and $predSamplesL1_{Cr}$, and the variables $predFlagL0$, $predFlagL1$, $refIdxL0$, $refIdxL1$ and $cIdx$ equal to 2 as inputs.

8.5.3.3.2 Reference picture selection process

Input to this process is a reference index $refIdxLX$.

Output of this process is a reference picture consisting of a two-dimensional array of luma samples $refPicLX_L$ and, when ChromaArrayType is not equal to 0, two two-dimensional arrays of chroma samples $refPicLX_{Cb}$ and $refPicLX_{Cr}$.

The output reference picture $RefPicListX[refIdxLX]$ consists of a $pic_width_in_luma_samples$ by $pic_height_in_luma_samples$ array of luma samples $refPicLX_L$ and, when ChromaArrayType is not equal to 0, two $PicWidthInSamplesC$ by $PicHeightInSamplesC$ arrays of chroma samples $refPicLX_{Cb}$ and $refPicLX_{Cr}$.

The reference picture sample arrays $refPicLX_L$, $refPicLX_{Cb}$ and $refPicLX_{Cr}$ correspond to decoded sample arrays S_L , S_{Cb} and S_{Cr} derived in clause 8.7 for a previously-decoded picture.

8.5.3.3.3 Fractional sample interpolation process

8.5.3.3.3.1 General

Inputs to this process are:

- a luma location (xCb, yCb) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture
- a luma location (xBl, yBl) specifying the top-left sample of the current luma prediction block relative to the top-left sample of the current luma coding block
- two variables $nPbW$ and $nPbH$ specifying the width and the height of the luma prediction block
- a luma motion vector $mvLX$ given in quarter-luma-sample units

- when ChromaArrayType is not equal to 0, a chroma motion vector mvCLX given in eighth-chroma-sample units
- the selected reference picture sample array refPicLX_L and, when ChromaArrayType is not equal to 0, the arrays refPicLX_{Cb} and refPicLX_{Cr}.

Outputs of this process are:

- an (nPbW)x(nPbH) array predSamplesLX_L of prediction luma sample values
- when ChromaArrayType is not equal to 0, two (nPbW / SubWidthC)x(nPbH / SubHeightC) arrays predSamplesLX_{Cb} and predSamplesLX_{Cr} of prediction chroma sample values.

The location (xPb, yPb) given in full-sample units of the upper-left luma samples of the current prediction block relative to the upper-left luma sample location of the given reference sample arrays is derived as follows:

$$xPb = xCb + xBl \quad (8-212)$$

$$yPb = yCb + yBl \quad (8-213)$$

Let (xInt_L, yInt_L) be a luma location given in full-sample units and (xFrac_L, yFrac_L) be an offset given in quarter-sample units. These variables are used only in this clause for specifying fractional-sample locations inside the reference sample arrays refPicLX_L, refPicLX_{Cb} and refPicLX_{Cr}.

For each luma sample location (x_L = 0..nPbW – 1, y_L = 0..nPbH – 1) inside the prediction luma sample array predSamplesLX_L, the corresponding prediction luma sample value predSamplesLX_L[x_L][y_L] is derived as follows:

- The variables xInt_L, yInt_L, xFrac_L and yFrac_L are derived as follows:

$$xInt_L = xPb + (mvLX[0] \gg 2) + x_L \quad (8-214)$$

$$yInt_L = yPb + (mvLX[1] \gg 2) + y_L \quad (8-215)$$

$$xFrac_L = mvLX[0] \& 3 \quad (8-216)$$

$$yFrac_L = mvLX[1] \& 3 \quad (8-217)$$

- The prediction luma sample value predSamplesLX_L[x_L][y_L] is derived by invoking the process specified in clause 8.5.3.3.2 with (xInt_L, yInt_L), (xFrac_L, yFrac_L) and refPicLX_L as inputs.

When ChromaArrayType is not equal to 0, the following applies.

Let (xInt_C, yInt_C) be a chroma location given in full-sample units and (xFrac_C, yFrac_C) be an offset given in one-eighth sample units. These variables are used only in this clause for specifying general fractional-sample locations inside the reference sample arrays refPicLX_{Cb} and refPicLX_{Cr}.

For each chroma sample location (x_C = 0..nPbW / SubWidthC – 1, y_C = 0..nPbH / SubHeightC – 1) inside the prediction chroma sample arrays predSamplesLX_{Cb} and predSamplesLX_{Cr}, the corresponding prediction chroma sample values predSamplesLX_{Cb}[x_C][y_C] and predSamplesLX_{Cr}[x_C][y_C] are derived as follows:

- The variables xInt_C, yInt_C, xFrac_C and yFrac_C are derived as follows:

$$xInt_C = (xPb / SubWidthC) + (mvCLX[0] \gg 3) + x_C \quad (8-218)$$

$$yInt_C = (yPb / SubHeightC) + (mvCLX[1] \gg 3) + y_C \quad (8-219)$$

$$xFrac_C = mvCLX[0] \& 7 \quad (8-220)$$

$$yFrac_C = mvCLX[1] \& 7 \quad (8-221)$$

- The prediction sample value predSamplesLX_{Cb}[x_C][y_C] is derived by invoking the process specified in clause 8.5.3.3.3 with (xInt_C, yInt_C), (xFrac_C, yFrac_C) and refPicLX_{Cb} as inputs.
- The prediction sample value predSamplesLX_{Cr}[x_C][y_C] is derived by invoking the process specified in clause 8.5.3.3.3 with (xInt_C, yInt_C), (xFrac_C, yFrac_C) and refPicLX_{Cr} as inputs.

8.5.3.3.2 Luma sample interpolation process

Inputs to this process are:

- a luma location in full-sample units (x_{Int_L} , y_{Int_L}),
- a luma location in fractional-sample units (x_{Frac_L} , y_{Frac_L}),
- the luma reference sample array $refPicLX_L$.

Output of this process is a predicted luma sample value $predSampleLX_L$

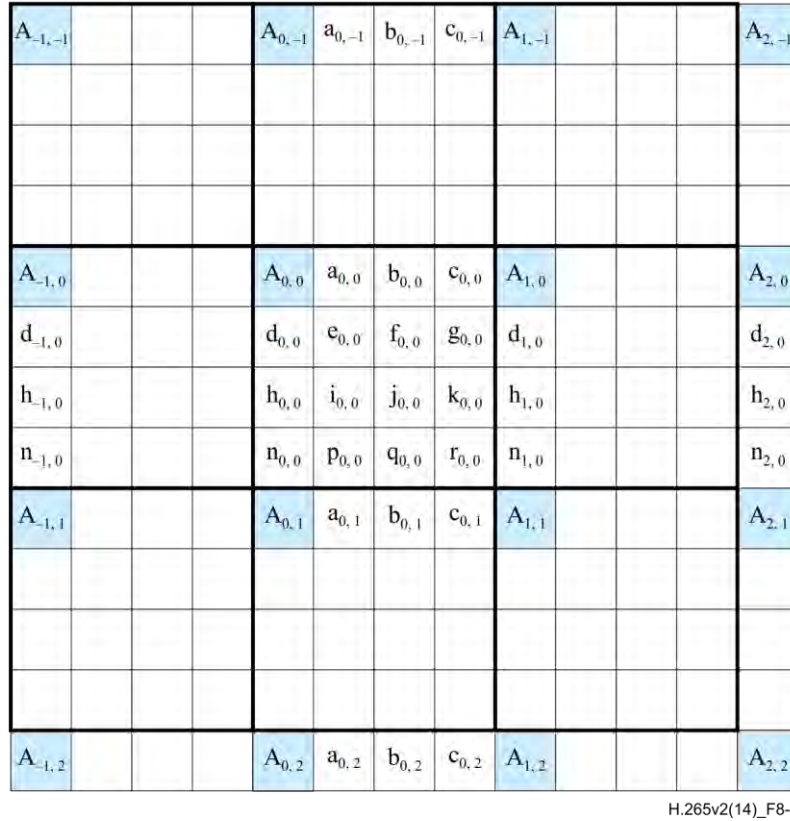

Figure 8-4 – Integer samples (shaded blocks with upper-case letters) and fractional sample positions (un-shaded blocks with lower-case letters) for quarter sample luma interpolation

In Figure 8-4, the positions labelled with upper-case letters $A_{i,j}$ within shaded blocks represent luma samples at full-sample locations inside the given two-dimensional array $refPicLX_L$ of luma samples. These samples may be used for generating the predicted luma sample value $predSampleLX_L$. The locations ($x_{A_{i,j}}$, $y_{A_{i,j}}$) for each of the corresponding luma samples $A_{i,j}$ inside the given array $refPicLX_L$ of luma samples are derived as follows:

$$x_{A_{i,j}} = \text{Clip3}(0, \text{pic_width_in_luma_samples} - 1, x_{Int_L} + i) \quad (8-222)$$

$$y_{A_{i,j}} = \text{Clip3}(0, \text{pic_height_in_luma_samples} - 1, y_{Int_L} + j) \quad (8-223)$$

The positions labelled with lower-case letters within un-shaded blocks represent luma samples at quarter-luma-sample fractional locations. The luma location offset in fractional-sample units (x_{Frac_L} , y_{Frac_L}) specifies which of the generated luma samples at full-sample and fractional-sample locations is assigned to the predicted luma sample value $predSampleLX_L$. This assignment is as specified in Table 8-8. The value of $predSampleLX_L$ is the output.

The variables $shift1$, $shift2$ and $shift3$ are derived as follows:

- The variable $shift1$ is set equal to $\text{Min}(4, \text{BitDepth}_Y - 8)$, the variable $shift2$ is set equal to 6 and the variable $shift3$ is set equal to $\text{Max}(2, 14 - \text{BitDepth}_Y)$.

Given the luma samples $A_{i,j}$ at full-sample locations ($x_{A_{i,j}}$, $y_{A_{i,j}}$), the luma samples $a_{0,0}$ to $r_{0,0}$ at fractional sample positions are derived as follows:

- The samples labelled $a_{0,0}$, $b_{0,0}$, $c_{0,0}$, $d_{0,0}$, $h_{0,0}$ and $n_{0,0}$ are derived by applying an 8-tap filter to the nearest integer position samples as follows:

$$a_{0,0} = (-A_{-3,0} + 4 * A_{-2,0} - 10 * A_{-1,0} + 58 * A_{0,0} + 17 * A_{1,0} - 5 * A_{2,0} + A_{3,0}) \gg shift1 \quad (8-224)$$

$$b_{0,0} = (-A_{-3,0} + 4 * A_{-2,0} - 11 * A_{-1,0} + 40 * A_{0,0} + 40 * A_{1,0} - 11 * A_{2,0} + 4 * A_{3,0} - A_{4,0}) >> \text{shift1} \quad (8-225)$$

$$c_{0,0} = (A_{-2,0} - 5 * A_{-1,0} + 17 * A_{0,0} + 58 * A_{1,0} - 10 * A_{2,0} + 4 * A_{3,0} - A_{4,0}) >> \text{shift1} \quad (8-226)$$

$$d_{0,0} = (-A_{0,-3} + 4 * A_{0,-2} - 10 * A_{0,-1} + 58 * A_{0,0} + 17 * A_{0,1} - 5 * A_{0,2} + A_{0,3}) >> \text{shift1} \quad (8-227)$$

$$h_{0,0} = (-A_{0,-3} + 4 * A_{0,-2} - 11 * A_{0,-1} + 40 * A_{0,0} + 40 * A_{0,1} - 11 * A_{0,2} + 4 * A_{0,3} - A_{0,4}) >> \text{shift1} \quad (8-228)$$

$$n_{0,0} = (A_{0,-2} - 5 * A_{0,-1} + 17 * A_{0,0} + 58 * A_{0,1} - 10 * A_{0,2} + 4 * A_{0,3} - A_{0,4}) >> \text{shift1} \quad (8-229)$$

- The samples labelled $e_{0,0}$, $i_{0,0}$, $p_{0,0}$, $f_{0,0}$, $j_{0,0}$, $q_{0,0}$, $g_{0,0}$, $k_{0,0}$ and $r_{0,0}$ are derived by applying an 8-tap filter to the samples $a_{0,i}$, $b_{0,i}$ and $c_{0,i}$ with $i = -3..4$ in the vertical direction as follows:

$$e_{0,0} = (-a_{0,-3} + 4 * a_{0,-2} - 10 * a_{0,-1} + 58 * a_{0,0} + 17 * a_{0,1} - 5 * a_{0,2} + a_{0,3}) >> \text{shift2} \quad (8-230)$$

$$i_{0,0} = (-a_{0,-3} + 4 * a_{0,-2} - 11 * a_{0,-1} + 40 * a_{0,0} + 40 * a_{0,1} - 11 * a_{0,2} + 4 * a_{0,3} - a_{0,4}) >> \text{shift2} \quad (8-231)$$

$$p_{0,0} = (a_{0,-2} - 5 * a_{0,-1} + 17 * a_{0,0} + 58 * a_{0,1} - 10 * a_{0,2} + 4 * a_{0,3} - a_{0,4}) >> \text{shift2} \quad (8-232)$$

$$f_{0,0} = (-b_{0,-3} + 4 * b_{0,-2} - 10 * b_{0,-1} + 58 * b_{0,0} + 17 * b_{0,1} - 5 * b_{0,2} + b_{0,3}) >> \text{shift2} \quad (8-233)$$

$$j_{0,0} = (-b_{0,-3} + 4 * b_{0,-2} - 11 * b_{0,-1} + 40 * b_{0,0} + 40 * b_{0,1} - 11 * b_{0,2} + 4 * b_{0,3} - b_{0,4}) >> \text{shift2} \quad (8-234)$$

$$q_{0,0} = (b_{0,-2} - 5 * b_{0,-1} + 17 * b_{0,0} + 58 * b_{0,1} - 10 * b_{0,2} + 4 * b_{0,3} - b_{0,4}) >> \text{shift2} \quad (8-235)$$

$$g_{0,0} = (-c_{0,-3} + 4 * c_{0,-2} - 10 * c_{0,-1} + 58 * c_{0,0} + 17 * c_{0,1} - 5 * c_{0,2} + c_{0,3}) >> \text{shift2} \quad (8-236)$$

$$k_{0,0} = (-c_{0,-3} + 4 * c_{0,-2} - 11 * c_{0,-1} + 40 * c_{0,0} + 40 * c_{0,1} - 11 * c_{0,2} + 4 * c_{0,3} - c_{0,4}) >> \text{shift2} \quad (8-237)$$

$$r_{0,0} = (c_{0,-2} - 5 * c_{0,-1} + 17 * c_{0,0} + 58 * c_{0,1} - 10 * c_{0,2} + 4 * c_{0,3} - c_{0,4}) >> \text{shift2} \quad (8-238)$$

8.5.3.3.3 Chroma sample interpolation process

This process is only invoked when ChromaArrayType is not equal to 0.

Inputs to this process are:

- a chroma location in full-sample units ($xInt_C$, $yInt_C$),
- a chroma location in eighth fractional-sample units ($xFrac_C$, $yFrac_C$),
- the chroma reference sample array $refPicLXC$.

Output of this process is a predicted chroma sample value $predSampleLXC$

H.265v2(14)_F8-5

Figure 8-5 – Integer samples (shaded blocks with upper-case letters) and fractional sample positions (un-shaded blocks with lower-case letters) for eighth sample chroma interpolation

In Figure 8-5, the positions labelled with upper-case letters $B_{i,j}$ within shaded blocks represent chroma samples at full-sample locations inside the given two-dimensional array refPicLXC of chroma samples. These samples may be used for generating the predicted chroma sample value predSampleLXC . The locations $(x_{B_{i,j}}, y_{B_{i,j}})$ for each of the corresponding chroma samples $B_{i,j}$ inside the given array refPicLXC of chroma samples are derived as follows:

$$x_{B_{i,j}} = \text{Clip3}(0, (\text{pic_width_in_luma_samples} / \text{SubWidthC}) - 1, x_{\text{IntC}} + i) \quad (8-239)$$

$$y_{B_{i,j}} = \text{Clip3}(0, (\text{pic_height_in_luma_samples} / \text{SubHeightC}) - 1, y_{\text{IntC}} + j) \quad (8-240)$$

The positions labelled with lower-case letters within un-shaded blocks represent chroma samples at eighth-pel sample fractional locations. The chroma location offset in fractional-sample units $(x_{\text{FracC}}, y_{\text{FracC}})$ specifies which of the generated chroma samples at full-sample and fractional-sample locations is assigned to the predicted chroma sample value predSampleLXC . This assignment is as specified in Table 8-9. The output is the value of predSampleLXC .

The variables shift1 , shift2 and shift3 are derived as follows:

- The variable shift1 is set equal to $\text{Min}(4, \text{BitDepthC} - 8)$, the variable shift2 is set equal to 6 and the variable shift3 is set equal to $\text{Max}(2, 14 - \text{BitDepthC})$.

Given the chroma samples $B_{i,j}$ at full-sample locations $(x_{B_{i,j}}, y_{B_{i,j}})$, the chroma samples $ab_{0,0}$ to $hh_{0,0}$ at fractional sample positions are derived as follows:

- The samples labelled $ab_{0,0}$, $ac_{0,0}$, $ad_{0,0}$, $ae_{0,0}$, $af_{0,0}$, $ag_{0,0}$ and $ah_{0,0}$ are derived by applying a 4-tap filter to the nearest integer position samples as follows:

$$ab_{0,0} = (-2 * B_{-1,0} + 58 * B_{0,0} + 10 * B_{1,0} - 2 * B_{2,0}) \gg \text{shift1} \quad (8-241)$$

$$ac_{0,0} = (-4 * B_{-1,0} + 54 * B_{0,0} + 16 * B_{1,0} - 2 * B_{2,0}) \gg \text{shift1} \quad (8-242)$$

$$ad_{0,0} = (-6 * B_{-1,0} + 46 * B_{0,0} + 28 * B_{1,0} - 4 * B_{2,0}) \gg \text{shift1} \quad (8-243)$$

$$ae_{0,0} = (-4 * B_{-1,0} + 36 * B_{0,0} + 36 * B_{1,0} - 4 * B_{2,0}) \gg \text{shift1} \quad (8-244)$$

$$af_{0,0} = (-4 * B_{-1,0} + 28 * B_{0,0} + 46 * B_{1,0} - 6 * B_{2,0}) \gg \text{shift1} \quad (8-245)$$

$$ag_{0,0} = (-2 * B_{-1,0} + 16 * B_{0,0} + 54 * B_{1,0} - 4 * B_{2,0}) \gg \text{shift1} \quad (8-246)$$

$$ah_{0,0} = (-2 * B_{-1,0} + 10 * B_{0,0} + 58 * B_{1,0} - 2 * B_{2,0}) \gg \text{shift1} \quad (8-247)$$

- The samples labelled $ba_{0,0}$, $ca_{0,0}$, $da_{0,0}$, $ea_{0,0}$, $fa_{0,0}$, $ga_{0,0}$ and $ha_{0,0}$ are derived by applying a 4-tap filter to the nearest integer position samples as follows:

$$ba_{0,0} = (-2 * B_{0,-1} + 58 * B_{0,0} + 10 * B_{0,1} - 2 * B_{0,2}) \gg \text{shift1} \quad (8-248)$$

$$ca_{0,0} = (-4 * B_{0,-1} + 54 * B_{0,0} + 16 * B_{0,1} - 2 * B_{0,2}) \gg \text{shift1} \quad (8-249)$$

$$da_{0,0} = (-6 * B_{0,-1} + 46 * B_{0,0} + 28 * B_{0,1} - 4 * B_{0,2}) \gg \text{shift1} \quad (8-250)$$

$$ea_{0,0} = (-4 * B_{0,-1} + 36 * B_{0,0} + 36 * B_{0,1} - 4 * B_{0,2}) \gg \text{shift1} \quad (8-251)$$

$$fa_{0,0} = (-4 * B_{0,-1} + 28 * B_{0,0} + 46 * B_{0,1} - 6 * B_{0,2}) \gg \text{shift1} \quad (8-252)$$

$$ga_{0,0} = (-2 * B_{0,-1} + 16 * B_{0,0} + 54 * B_{0,1} - 4 * B_{0,2}) \gg \text{shift1} \quad (8-253)$$

$$ha_{0,0} = (-2 * B_{0,-1} + 10 * B_{0,0} + 58 * B_{0,1} - 2 * B_{0,2}) \gg \text{shift1} \quad (8-254)$$

- The samples labelled $bX_{0,0}$, $cX_{0,0}$, $dX_{0,0}$, $eX_{0,0}$, $fX_{0,0}$, $gX_{0,0}$ and $hX_{0,0}$ for X being replaced by b, c, d, e, f, g and h, respectively, are derived by applying a 4-tap filter to the intermediate values $aX_{0,i}$ with $i = -1..2$ in the vertical direction as follows:

$$bX_{0,0} = (-2 * aX_{0,-1} + 58 * aX_{0,0} + 10 * aX_{0,1} - 2 * aX_{0,2}) \gg \text{shift2} \quad (8-255)$$

$$cX_{0,0} = (-4 * aX_{0,-1} + 54 * aX_{0,0} + 16 * aX_{0,1} - 2 * aX_{0,2}) \gg \text{shift2} \quad (8-256)$$

$$dX_{0,0} = (-6 * aX_{0,-1} + 46 * aX_{0,0} + 28 * aX_{0,1} - 4 * aX_{0,2}) \gg \text{shift2} \quad (8-257)$$

$$eX_{0,0} = (-4 * aX_{0,-1} + 36 * aX_{0,0} + 36 * aX_{0,1} - 4 * aX_{0,2}) \gg \text{shift2} \quad (8-258)$$

$$fX_{0,0} = (-4 * aX_{0,-1} + 28 * aX_{0,0} + 46 * aX_{0,1} - 6 * aX_{0,2}) \gg \text{shift2} \quad (8-259)$$

$$gX_{0,0} = (-2 * aX_{0,-1} + 16 * aX_{0,0} + 54 * aX_{0,1} - 4 * aX_{0,2}) \gg \text{shift2} \quad (8-260)$$

$$hX_{0,0} = (-2 * aX_{0,-1} + 10 * aX_{0,0} + 58 * aX_{0,1} - 2 * aX_{0,2}) \gg \text{shift2} \quad (8-261)$$

Table 8-9 – Assignment of the chroma prediction sample predSampleLX_C for (X, Y) being replaced by (1, b), (2, c), (3, d), (4, e), (5, f), (6, g) and (7, h), respectively

8.5.3.3.4 Weighted sample prediction process

8.5.3.3.4.1 General

Inputs to this process are:

- two variables $nPbW$ and $nPbH$ specifying the width and the height of the current prediction block,
- two $(nPbW) \times (nPbH)$ arrays predSamplesL0 and predSamplesL1 ,
- the prediction list utilization flags, predFlagL0 and predFlagL1 ,
- the reference indices refIdxL0 and refIdxL1 ,
- a variable $cIdx$ specifying colour component index.

Output of this process is the $(nPbW) \times (nPbH)$ array pbSamples of prediction sample values.

The variable bitDepth is derived as follows:

- If cIdx is equal to 0, bitDepth is set equal to BitDepth_Y.
- Otherwise, bitDepth is set equal to BitDepth_C.

The variable weightedPredFlag is derived as follows:

- If slice_type is equal to P, weightedPredFlag is set equal to weighted_pred_flag.
- Otherwise (slice_type is equal to B), weightedPredFlag is set equal to weighted_bipred_flag.

The following applies:

- If weightedPredFlag is equal to 0, the array pbSamples of the prediction samples is derived by invoking the default weighted sample prediction process as specified in clause 8.5.3.3.4.2 with the prediction block width nPbW, the prediction block height nPbH, two $(nPbW) \times (nPbH)$ arrays predSamplesL0 and predSamplesL1, the prediction list utilization flags predFlagL0 and predFlagL1 and the bit depth bitDepth as inputs.
- Otherwise (weightedPredFlag is equal to 1), the array pbSamples of the prediction samples is derived by invoking the weighted sample prediction process as specified in clause 8.5.3.3.4.3 with the prediction block width nPbW, the prediction block height nPbH, two $(nPbW) \times (nPbH)$ arrays predSamplesL0 and predSamplesL1, the prediction list utilization flags predFlagL0 and predFlagL1, the reference indices refIdxL0 and refIdxL1, the colour component index cIdx and the bit depth bitDepth as inputs.

8.5.3.3.4.2 Default weighted sample prediction process

Inputs to this process are:

- two variables nPbW and nPbH specifying the width and the height of the current prediction block,
- two $(nPbW) \times (nPbH)$ arrays predSamplesL0 and predSamplesL1,
- the prediction list utilization flags, predFlagL0, and predFlagL1,
- a bit depth of samples, bitDepth.

Output of this process is the $(nPbW) \times (nPbH)$ array pbSamples of prediction sample values.

Variables shift1, shift2, offset1 and offset2 are derived as follows:

- The variable shift1 is set equal to $\text{Max}(2, 14 - \text{bitDepth})$ and the variable shift2 is set equal to $\text{Max}(3, 15 - \text{bitDepth})$.
- The variable offset1 is set equal to $1 \ll (\text{shift1} - 1)$.
- The variable offset2 is set equal to $1 \ll (\text{shift2} - 1)$.

Depending on the values of predFlagL0 and predFlagL1, the prediction samples pbSamples[x][y] with $x = 0..nPbW - 1$ and $y = 0..nPbH - 1$ are derived as follows:

- If predFlagL0 is equal to 1 and predFlagL1 is equal to 0, the prediction sample values are derived as follows:

$$\text{pbSamples}[x][y] = \text{Clip3}(0, (1 \ll \text{bitDepth}) - 1, (\text{predSamplesL0}[x][y] + \text{offset1}) \gg \text{shift1}) \quad (8-262)$$

- Otherwise, if predFlagL0 is equal to 0 and predFlagL1 is equal to 1, the prediction sample values are derived as follows:

$$\text{pbSamples}[x][y] = \text{Clip3}(0, (1 \ll \text{bitDepth}) - 1, (\text{predSamplesL1}[x][y] + \text{offset1}) \gg \text{shift1}) \quad (8-263)$$

- Otherwise (predFlagL0 is equal to 1 and predFlagL1 is equal to 1), the prediction sample values are derived as follows:

$$\text{pbSamples}[x][y] = \text{Clip3}(0, (1 \ll \text{bitDepth}) - 1, (\text{predSamplesL0}[x][y] + \text{predSamplesL1}[x][y] + \text{offset2}) \gg \text{shift2}) \quad (8-264)$$

8.5.3.3.4.3 Explicit weighted sample prediction process

Inputs to this process are:

- two variables nPbW and nPbH specifying the width and the height of the current prediction block,
- two (nPbW)x(nPbH) arrays predSamplesL0 and predSamplesL1,
- the prediction list utilization flags, predFlagL0 and predFlagL1,
- the reference indices, refIdxL0 and refIdxL1,
- a variable cIdx specifying colour component index,
- a bit depth of samples, bitDepth.

Output of this process is the (nPbW)x(nPbH) array pbSamples of prediction sample values.

The variable shift1 is set equal to $\text{Max}(2, 14 - \text{bitDepth})$.

The variables log2Wd, o0, o1, w0 and w1 are derived as follows:

- If cIdx is equal to 0 for luma samples, the following applies:

$$\text{log2Wd} = \text{luma_log2_weight_denom} + \text{shift1} \quad (8-265)$$

$$\text{w0} = \text{LumaWeightL0}[\text{refIdxL0}] \quad (8-266)$$

$$\text{w1} = \text{LumaWeightL1}[\text{refIdxL1}] \quad (8-267)$$

$$\text{o0} = \text{luma_offset_l0}[\text{refIdxL0}] \ll \text{WpOffsetBdShift}_Y \quad (8-268)$$

$$\text{o1} = \text{luma_offset_l1}[\text{refIdxL1}] \ll \text{WpOffsetBdShift}_Y \quad (8-269)$$

- Otherwise (cIdx is not equal to 0 for chroma samples), the following applies:

$$\text{log2Wd} = \text{ChromaLog2WeightDenom} + \text{shift1} \quad (8-270)$$

$$\text{w0} = \text{ChromaWeightL0}[\text{refIdxL0}][\text{cIdx} - 1] \quad (8-271)$$

$$\text{w1} = \text{ChromaWeightL1}[\text{refIdxL1}][\text{cIdx} - 1] \quad (8-272)$$

$$\text{o0} = \text{ChromaOffsetL0}[\text{refIdxL0}][\text{cIdx} - 1] \ll \text{WpOffsetBdShift}_C \quad (8-273)$$

$$\text{o1} = \text{ChromaOffsetL1}[\text{refIdxL1}][\text{cIdx} - 1] \ll \text{WpOffsetBdShift}_C \quad (8-274)$$

The prediction sample pbSamples[x][y] with $x = 0..nPbW - 1$ and $y = 0..nPbH - 1$ are derived as follows:

- If the predFlagL0 is equal to 1 and predFlagL1 is equal to 0, the prediction sample values are derived as follows:

$$\text{pbSamples}[x][y] = \text{Clip3}(0, (1 \ll \text{bitDepth}) - 1, ((\text{predSamplesL0}[x][y] * \text{w0} + 2^{\text{log2Wd}-1}) \gg \text{log2Wd}) + \text{o0}) \quad (8-275)$$

- Otherwise, if the predFlagL0 is equal to 0 and predFlagL1 is equal to 1, the prediction sample values are derived as follows:

$$\text{pbSamples}[x][y] = \text{Clip3}(0, (1 \ll \text{bitDepth}) - 1, ((\text{predSamplesL1}[x][y] * \text{w1} + 2^{\text{log2Wd}-1}) \gg \text{log2Wd}) + \text{o1}) \quad (8-276)$$

- Otherwise (predFlagL0 is equal to 1 and predFlagL1 is equal to 1), the prediction sample values are derived as follows:

$$\text{pbSamples}[x][y] = \text{Clip3}(0, (1 \ll \text{bitDepth}) - 1, (\text{predSamplesL0}[x][y] * \text{w0} + \text{predSamplesL1}[x][y] * \text{w1} + ((\text{o0} + \text{o1} + 1) \ll \text{log2Wd})) \gg (\text{log2Wd} + 1)) \quad (8-277)$$

8.5.4 Decoding process for the residual signal of coding units coded in inter prediction mode

8.5.4.1 General

Inputs to this process are:

- a luma location (x_{Cb} , y_{Cb}) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a variable $\log_2 CbSize$ specifying the size of the current luma coding block.

Outputs of this process are:

- an $(nCbS_L) \times (nCbS_L)$ array $resSamples_L$ of luma residual samples, where $nCbS_L$ is derived as specified below,
- when $ChromaArrayType$ is not equal to 0, an $(nCbSw_C) \times (nCbSh_C)$ array $resSamples_{Cb}$ of chroma residual samples for the component Cb, where $nCbSw_C$ and $nCbSh_C$ are derived as specified below,
- when $ChromaArrayType$ is not equal to 0, an $(nCbSw_C) \times (nCbSh_C)$ array $resSamples_{Cr}$ of chroma residual samples for the component Cr, where $nCbSw_C$ and $nCbSh_C$ are derived as specified below.

The variable $nCbS_L$ is set equal to $1 \ll \log_2 CbSize$. When $ChromaArrayType$ is not equal to 0, the variable $nCbSw_C$ is set equal to $nCbS_L / SubWidthC$ and the variable $nCbSh_C$ is set equal to $nCbS_L / SubHeightC$.

Let $resSamples_L$ be an $(nCbS_L) \times (nCbS_L)$ array of luma residual samples and, when $ChromaArrayType$ is not equal to 0, let $resSamples_{Cb}$ and $resSamples_{Cr}$ be two $(nCbSw_C) \times (nCbSh_C)$ arrays of chroma residual samples.

Depending on the value of rqt_root_cbf , the following applies:

- If rqt_root_cbf is equal to 0 or $cu_skip_flag[x_{Cb}][y_{Cb}]$ is equal to 1, all samples of the $(nCbS_L) \times (nCbS_L)$ array $resSamples_L$ and, when $ChromaArrayType$ is not equal to 0, all samples of the two $(nCbSw_C) \times (nCbSh_C)$ arrays $resSamples_{Cb}$ and $resSamples_{Cr}$ are set equal to 0.
- Otherwise (rqt_root_cbf is equal to 1), the following ordered steps apply:
 1. The decoding process for luma residual blocks as specified in clause 8.5.4.2 below is invoked with the luma location (x_{Cb} , y_{Cb}), the luma location (x_{B0} , y_{B0}) set equal to (0, 0), the variable $\log_2 TrafoSize$ set equal to $\log_2 CbSize$, the variable $trafoDepth$ set equal to 0, the variable $nCbS$ set equal to $nCbS_L$ and the $(nCbS_L) \times (nCbS_L)$ array $resSamples_L$ as inputs, and the output is a modified version of the $(nCbS_L) \times (nCbS_L)$ array $resSamples_L$.
 2. When $ChromaArrayType$ is not equal to 0, the decoding process for chroma residual blocks as specified in clause 8.5.4.3 is invoked with the luma location (x_{Cb} , y_{Cb}), the luma location (x_{B0} , y_{B0}) set equal to (0, 0), the variable $\log_2 TrafoSize$ set equal to $\log_2 CbSize$, the variable $trafoDepth$ set equal to 0, the variable $cIdx$ set equal to 1, the variable $nCbSw$ set equal to $nCbSw_C$, the variable $nCbSh$ set equal to $nCbSh_C$ and the $(nCbSw_C) \times (nCbSh_C)$ array $resSamples_{Cb}$ as inputs, and the output is a modified version of the $(nCbSw_C) \times (nCbSh_C)$ array $resSamples_{Cb}$.
 3. When $ChromaArrayType$ is not equal to 0, the decoding process for chroma residual blocks as specified in clause 8.5.4.3 is invoked with the luma location (x_{Cb} , y_{Cb}), the luma location (x_{B0} , y_{B0}) set equal to (0, 0), the variable $\log_2 TrafoSize$ set equal to $\log_2 CbSize$, the variable $trafoDepth$ set equal to 0, the variable $cIdx$ set equal to 2, the variable $nCbSw$ set equal to $nCbSw_C$, the variable $nCbSh$ set equal to $nCbSh_C$ and the $(nCbSw_C) \times (nCbSh_C)$ array $resSamples_{Cr}$ as inputs, and the output is a modified version of the $(nCbSw_C) \times (nCbSh_C)$ array $resSamples_{Cr}$.
 4. When $residual_adaptive_colour_transform_enabled_flag$ is equal to 1, the residual modification process for blocks using adaptive colour transform as specified in clause 8.6.8 is invoked with location (x_{Cb} , y_{Cb}), the variable $\log_2 TrafoSize$ set equal to $\log_2 CbSize$, the variable $trafoDepth$ set equal to 0, the variable $resSampleArrayL$ set equal to $resSamples_L$, the variable $resSampleArrayCb$ set equal to $resSamples_{Cb}$ and the variable $resSampleArrayCr$ set equal to $resSamples_{Cr}$ as inputs, and the outputs are modified versions of $resSample_L$, $resSample_{Cb}$ and $resSample_{Cr}$.

8.5.4.2 Decoding process for luma residual blocks

Inputs to this process are:

- a luma location (x_{Cb} , y_{Cb}) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a luma location (x_{B0} , y_{B0}) specifying the top-left sample of the current luma block relative to the top-left sample of the current luma coding block,
- a variable $\log_2 TrafoSize$ specifying the size of the current luma block,
- a variable $trafoDepth$ specifying the hierarchy depth of the current luma block relative to the luma coding block,
- a variable $nCbS$ specifying the size of the current luma coding block,
- an $(nCbS) \times (nCbS)$ array $resSamples$ of luma residual samples.

Output of this process is a modified version of the $(nCbS) \times (nCbS)$ array of luma residual samples.

Depending on the value of $split_transform_flag[xCb + xB0][yCb + yB0][trafoDepth]$, the following applies:

- If $split_transform_flag[xCb + xB0][yCb + yB0][trafoDepth]$ is equal to 1, the following ordered steps apply:
 1. The variables $xB1$ and $yB1$ are derived as follows:
 - The variable $xB1$ is set equal to $xB0 + (1 \ll (\log2TrafoSize - 1))$.
 - The variable $yB1$ is set equal to $yB0 + (1 \ll (\log2TrafoSize - 1))$.
 2. The decoding process for luma residual blocks as specified in this clause is invoked with the luma location (xCb, yCb) , the luma location $(xB0, yB0)$, the variable $\log2TrafoSize$ set equal to $\log2TrafoSize - 1$, the variable $trafoDepth$ set equal to $trafoDepth + 1$, the variable $nCbS$ and the $(nCbS) \times (nCbS)$ array $resSamples$ as inputs, and the output is a modified version of the $(nCbS) \times (nCbS)$ array $resSamples$.
 3. The decoding process for luma residual blocks as specified in this clause is invoked with the luma location (xCb, yCb) , the luma location $(xB1, yB0)$, the variable $\log2TrafoSize$ set equal to $\log2TrafoSize - 1$, the variable $trafoDepth$ set equal to $trafoDepth + 1$, the variable $nCbS$ and the $(nCbS) \times (nCbS)$ array $resSamples$ as inputs, and the output is a modified version of the $(nCbS) \times (nCbS)$ array $resSamples$.
 4. The decoding process for luma residual blocks as specified in this clause is invoked with the luma location (xCb, yCb) , the luma location $(xB0, yB1)$, the variable $\log2TrafoSize$ set equal to $\log2TrafoSize - 1$, the variable $trafoDepth$ set equal to $trafoDepth + 1$, the variable $nCbS$ and the $(nCbS) \times (nCbS)$ array $resSamples$ as inputs, and the output is a modified version of the $(nCbS) \times (nCbS)$ array $resSamples$.
 5. The decoding process for luma residual blocks as specified in this clause is invoked with the luma location (xCb, yCb) , the luma location $(xB1, yB1)$, the variable $\log2TrafoSize$ set equal to $\log2TrafoSize - 1$, the variable $trafoDepth$ set equal to $trafoDepth + 1$, the variable $nCbS$ and the $(nCbS) \times (nCbS)$ array $resSamples$ as inputs, and the output is a modified version of the $(nCbS) \times (nCbS)$ array $resSamples$.
- Otherwise ($split_transform_flag[xCb + xB0][yCb + yB0][trafoDepth]$ is equal to 0), the following ordered steps apply:
 1. The variable $nTbS$ is set equal to $1 \ll \log2TrafoSize$.
 2. The scaling and transformation process as specified in clause 8.6.2 is invoked with the luma location $(xCb + xB0, yCb + yB0)$, the variable $trafoDepth$, the variable $cIdx$ set equal to 0 and the transform size $trafoSize$ set equal to $nTbS$ as inputs, and the output is an $(nTbS) \times (nTbS)$ array $transformBlock$.
 3. When $explicit_rdpcm_flag[xCb + xB0][yCb + yB0][0]$ is equal to 1, the directional residual modification process for blocks using a transform bypass as specified in clause 8.6.5 is invoked with the variable $mDir$ set equal to $explicit_rdpcm_dir_flag[xCb + xB0][yCb + yB0][0]$, the variable $nTbS$ and the $(nTbS) \times (nTbS)$ array r set equal to the array $transformBlock$ as inputs, and the output is a modified $(nTbS) \times (nTbS)$ array $transformBlock$.
 4. The $(nCbS) \times (nCbS)$ residual sample array of the current coding block $resSamples$ is modified as follows:

$$resSamples[xB0 + i, yB0 + j] = transformBlock[i, j], \text{ with } i = 0..nTbS - 1, j = 0..nTbS - 1 \text{ (8-278)}$$

8.5.4.3 Decoding process for chroma residual blocks

This process is only invoked when $ChromaArrayType$ is not equal to 0.

Inputs to this process are:

- a luma location (xCb, yCb) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a luma location $(xB0, yB0)$ specifying the top-left luma sample of the current chroma block relative to the top-left sample of the current luma coding block,
- a variable $\log2TrafoSize$ specifying the size of the current chroma block in luma samples,
- a variable $trafoDepth$ specifying the hierarchy depth of the current chroma block relative to the chroma coding block,
- a variable $cIdx$ specifying the chroma component of the current block,
- the variables $nCbSw$ and $nCbSh$ specifying the width and height, respectively, of the current chroma coding block,
- an $(nCbSw) \times (nCbSh)$ array $resSamples$ of chroma residual samples.

Output of this process is a modified version of the $(nCbSw) \times (nCbSh)$ array of chroma residual samples.

The variable `splitChromaFlag` is derived as follows:

- If `split_transform_flag[xCb + xB0][yCb + yB0][trafoDepth]` is equal to 1 and one or more of the following conditions are met, `splitChromaFlag` is set equal to 1:
 - `log2TrafoSize` is greater than 3.
 - `ChromaArrayType` is equal to 3.
- Otherwise (`split_transform_flag[xCb + xB0][yCb + yB0][trafoDepth]` is equal to 0 or both `log2TrafoSize` is equal to 3 and `ChromaArrayType` is not equal to 3), `splitChromaFlag` is set equal to 0.

Depending on the value of `splitChromaFlag`, the following applies:

- If `splitChromaFlag` is equal to 1, the following ordered steps apply:
 1. The variables `xB1` and `yB1` are derived as follows:
 - The variable `xB1` is set equal to $xB0 + (1 \ll (\log2TrafoSize - 1))$.
 - The variable `yB1` is set equal to $yB0 + (1 \ll (\log2TrafoSize - 1))$.
 2. The decoding process for residual chroma blocks as specified in this clause is invoked with the luma location (xCb, yCb) , the luma location $(xB0, yB0)$, the variable `log2TrafoSize` set equal to `log2TrafoSize - 1`, the variable `trafoDepth` set equal to `trafoDepth + 1`, the variable `cIdx`, the variable `nCbSw`, the variable `nCbSh` and the $(nCbSw) \times (nCbSh)$ array `resSamples` as inputs, and the output is a modified version of the $(nCbSw) \times (nCbSh)$ array `resSamples`.
 3. The decoding process for residual chroma blocks as specified in this clause is invoked with the luma location (xCb, yCb) , the luma location $(xB1, yB0)$, the variable `log2TrafoSize` set equal to `log2TrafoSize - 1`, the variable `trafoDepth` set equal to `trafoDepth + 1`, the variable `cIdx`, the variable `nCbSw`, the variable `nCbSh` and the $(nCbSw) \times (nCbSh)$ array `resSamples` as inputs, and the output is a modified version of the $(nCbSw) \times (nCbSh)$ array `resSamples`.
 4. The decoding process for residual chroma blocks as specified in this clause is invoked with the luma location (xCb, yCb) , the luma location $(xB0, yB1)$, the variable `log2TrafoSize` set equal to `log2TrafoSize - 1`, the variable `trafoDepth` set equal to `trafoDepth + 1`, the variable `cIdx`, the variable `nCbSw`, the variable `nCbSh` and the $(nCbSw) \times (nCbSh)$ array `resSamples` as inputs, and the output is a modified version of the $(nCbSw) \times (nCbSh)$ array `resSamples`.
 5. The decoding process for residual chroma blocks as specified in this clause is invoked with the luma location (xCb, yCb) , the luma location $(xB1, yB1)$, the variable `log2TrafoSize` set equal to `log2TrafoSize - 1`, the variable `trafoDepth` set equal to `trafoDepth + 1`, the variable `cIdx`, the variable `nCbSw`, the variable `nCbSh` and the $(nCbSw) \times (nCbSh)$ array `resSamples` as inputs, and the output is a modified version of the $(nCbSw) \times (nCbSh)$ array `resSamples`.
- Otherwise (`splitChromaFlag` is equal to 0), for the variable `blkIdx` proceeding over the values $0..(ChromaArrayType == 2 ? 1 : 0)$, the following ordered steps apply:
 1. The variable `nTbS` is set equal to $(1 \ll \log2TrafoSize) / SubWidthC$.
 2. The variable `yBN` is set equal to $yB0 + blkIdx * nTbS * SubHeightC$.
 3. The scaling and transformation process as specified in clause 8.6.2 is invoked with the luma location $(xCb + xB0, yCb + yBN)$, the variable `trafoDepth`, the variable `cIdx` and the transform size `trafoSize` set equal to `nTbS` as inputs, and the output is an $(nTbS) \times (nTbS)$ array `transformBlock`.
 4. When `explicit_rdpem_flag[xCb + xB0][yCb + yBN][cIdx]` is equal to 1, the directional residual modification process for blocks using a transform bypass as specified in clause 8.6.5 is invoked with the variable `mDir` set equal to `explicit_rdpem_dir_flag[xCb + xB0][yCb + yBN][cIdx]`, the variable `nTbS` and the $(nTbS) \times (nTbS)$ array `r` set equal to the array `transformBlock` as inputs, and the output is a modified $(nTbS) \times (nTbS)$ array `transformBlock`.
 5. When `cross_component_prediction_enabled_flag` is equal to 1 and `ChromaArrayType` is equal to 3, the residual modification process for transform blocks using cross-component prediction as specified in clause 8.6.6 is invoked with the transform block location $(xCb + xB0, yCb + yB0)$, the variable `nTbS`, the variable `cIdx`, the $(nTbS) \times (nTbS)$ array `rT` set equal to the corresponding luma residual sample array `transformBlock` of the current transform block and the $(nTbS) \times (nTbS)$ array `r` set equal to the array `transformBlock` as inputs, and the output is a modified $(nTbS) \times (nTbS)$ array `resSamples`.

6. The $(nCbS) \times (nCbS)$ residual sample array of the current coding block $resSamples$ is modified as follows, for $i = 0..nTbS - 1, j = 0..nTbS - 1$:

$$resSamples[(xCb + xB0) / SubWidthC + i, (yCb + yBN) / SubHeightC + j] = transformBlock[i, j] \quad (8-279)$$

8.6 Scaling, transformation and array construction process prior to deblocking filter process

8.6.1 Derivation process for quantization parameters

Input to this process is a luma location (xCb, yCb) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture.

In this process, the variable Qp_Y , the luma quantization parameter Qp'_Y and the chroma quantization parameters Qp'_{Cb} and Qp'_{Cr} are derived.

The luma location (xQg, yQg) , specifies the top-left luma sample of the current quantization group relative to the top-left luma sample of the current picture. The horizontal and vertical positions xQg and yQg are set equal to $xCb - (xCb \& ((1 \ll \text{Log2MinCuQpDeltaSize}) - 1))$ and $yCb - (yCb \& ((1 \ll \text{Log2MinCuQpDeltaSize}) - 1))$, respectively. The luma size of a quantization group, $\text{Log2MinCuQpDeltaSize}$, determines the luma size of the smallest area inside a CTB that shares the same qP_{Y_PREL} .

The predicted luma quantization parameter qP_{Y_PREL} is derived by the following ordered steps:

1. The variable qP_{Y_PREV} is derived as follows:
 - If one or more of the following conditions are true, qP_{Y_PREV} is set equal to SliceQp_Y :
 - The current quantization group is the first quantization group in a slice.
 - The current quantization group is the first quantization group in a tile.
 - The current quantization group is the first quantization group in a CTB row of a tile and `entropy_coding_sync_enabled_flag` is equal to 1.
 - Otherwise, qP_{Y_PREV} is set equal to the luma quantization parameter Qp_Y of the last coding unit in the previous quantization group in decoding order.
2. The availability derivation process for a block in z-scan order as specified in clause 6.4.1 is invoked with the location $(xCurr, yCurr)$ set equal to (xCb, yCb) and the neighbouring location $(xNbY, yNbY)$ set equal to $(xQg - 1, yQg)$ as inputs, and the output is assigned to `availableA`. The variable qP_{Y_A} is derived as follows:
 - If one or more of the following conditions are true, qP_{Y_A} is set equal to qP_{Y_PREV} :
 - `availableA` is equal to FALSE.
 - the CTB address `ctbAddrA` of the CTB containing the luma coding block covering the luma location $(xQg - 1, yQg)$ is not equal to `CtbAddrInTs`, where `ctbAddrA` is derived as follows:

$$\begin{aligned} xTmp &= (xQg - 1) \gg \text{MinTbLog2SizeY} \\ yTmp &= yQg \gg \text{MinTbLog2SizeY} \\ \text{minTbAddrA} &= \text{MinTbAddrZs}[xTmp][yTmp] \\ \text{ctbAddrA} &= \text{minTbAddrA} \gg (2 * (\text{CtbLog2SizeY} - \text{MinTbLog2SizeY})) \end{aligned} \quad (8-280)$$
 - Otherwise, qP_{Y_A} is set equal to the luma quantization parameter Qp_Y of the coding unit containing the luma coding block covering $(xQg - 1, yQg)$.
3. The availability derivation process for a block in z-scan order as specified in clause 6.4.1 is invoked with the location $(xCurr, yCurr)$ set equal to (xCb, yCb) and the neighbouring location $(xNbY, yNbY)$ set equal to $(xQg, yQg - 1)$ as inputs, and the output is assigned to `availableB`. The variable qP_{Y_B} is derived as follows:
 - If one or more of the following conditions are true, qP_{Y_B} is set equal to qP_{Y_PREV} :
 - `availableB` is equal to FALSE.
 - the CTB address `ctbAddrB` of the CTB containing the luma coding block covering the luma location $(xQg, yQg - 1)$ is not equal to `CtbAddrInTs`, where `ctbAddrB` is derived as follows:

$$\begin{aligned} xTmp &= xQg \gg \text{MinTbLog2SizeY} \\ yTmp &= (yQg - 1) \gg \text{MinTbLog2SizeY} \end{aligned}$$

$$\begin{aligned} \text{minTbAddrB} &= \text{MinTbAddrZs}[\text{xTmp}][\text{yTmp}] \\ \text{ctbAddrB} &= \text{minTbAddrB} \gg (2 * (\text{CtbLog2SizeY} - \text{MinTbLog2SizeY})) \end{aligned} \quad (8-281)$$

- Otherwise, qP_{Y_B} is set equal to the luma quantization parameter Qp_Y of the coding unit containing the luma coding block covering ($xQg, yQg - 1$).

4. The predicted luma quantization parameter qP_{Y_PRED} is derived as follows:

$$qP_{Y_PRED} = (qP_{Y_A} + qP_{Y_B} + 1) \gg 1 \quad (8-282)$$

The variable Qp_Y is derived as follows:

$$Qp_Y = ((qP_{Y_PRED} + \text{CuQpDeltaVal} + 52 + 2 * QpBdOffset_Y) \% (52 + QpBdOffset_Y)) - QpBdOffset_Y \quad (8-283)$$

The luma quantization parameter Qp'_Y is derived as follows:

$$Qp'_Y = Qp_Y + QpBdOffset_Y \quad (8-284)$$

When ChromaArrayType is not equal to 0, the following applies:

- The variables qP_{Cb} and qP_{Cr} are derived as follows:
- If $\text{tu_residual_act_flag}[\text{xTbY}][\text{yTbY}]$ is equal to 0, the following applies:

$$qPi_{Cb} = \text{Clip3}(-QpBdOffset_C, 57, Qp_Y + \text{pps_cb_qp_offset} + \text{slice_cb_qp_offset} + \text{CuQpOffset}_{Cb}) \quad (8-285)$$

$$qPi_{Cr} = \text{Clip3}(-QpBdOffset_C, 57, Qp_Y + \text{pps_cr_qp_offset} + \text{slice_cr_qp_offset} + \text{CuQpOffset}_{Cr}) \quad (8-286)$$

- Otherwise ($\text{tu_residual_act_flag}[\text{xTbY}][\text{yTbY}]$ is equal to 1), the following applies:

$$qPi_{Cb} = \text{Clip3}(-QpBdOffset_C, 57, Qp_Y + \text{PpsActQpOffset}_{Cb} + \text{slice_act_cb_qp_offset} + \text{CuQpOffset}_{Cb}) \quad (8-287)$$

$$qPi_{Cr} = \text{Clip3}(-QpBdOffset_C, 57, Qp_Y + \text{PpsActQpOffset}_{Cr} + \text{slice_act_cr_qp_offset} + \text{CuQpOffset}_{Cr}) \quad (8-288)$$

- If ChromaArrayType is equal to 1, the variables qP_{Cb} and qP_{Cr} are set equal to the value of Qp_C as specified in Table 8-10 based on the index qPi equal to qPi_{Cb} and qPi_{Cr} , respectively.
- Otherwise, the variables qP_{Cb} and qP_{Cr} are set equal to $\text{Min}(qPi, 51)$, based on the index qPi equal to qPi_{Cb} and qPi_{Cr} , respectively.
- The chroma quantization parameters for the Cb and Cr components, Qp'_{Cb} and Qp'_{Cr} , are derived as follows:

$$Qp'_{Cb} = qP_{Cb} + QpBdOffset_C \quad (8-289)$$

$$Qp'_{Cr} = qP_{Cr} + QpBdOffset_C \quad (8-290)$$

Table 8-10 – Specification of Qp_C as a function of qPi for ChromaArrayType equal to 1

qPi	< 30	30	31	32	33	34	35	36	37	38	39	40	41	42	43	> 43
Qp_C	= qPi	29	30	31	32	33	33	34	34	35	35	36	36	37	37	= $qPi - 6$

8.6.2 Scaling and transformation process

Inputs to this process are:

- a luma location ($xTbY, yTbY$) specifying the top-left sample of the current luma transform block relative to the top-left luma sample of the current picture,

- a variable `trafoDepth` specifying the hierarchy depth of the current block relative to the coding block,
- a variable `cIdx` specifying the colour component of the current block,
- a variable `nTbS` specifying the size of the current transform block.

Output of this process is the $(nTbS) \times (nTbS)$ array of residual samples r with elements $r[x][y]$.

The quantization parameter qP is derived as follows:

- If `cIdx` is equal to 0, the following applies:

$$qP = \text{Clip3}(0, 51 + QpBdOffsetY, Qp'Y + (tu_residual_act_flag[xTbY][yTbY] ? PpsActQpOffsetY + slice_act_y_qp_offset : 0)) \quad (8-291)$$

- Otherwise, if `cIdx` is equal to 1, the following applies:

$$qP = Qp'_{cb} \quad (8-292)$$

- Otherwise (`cIdx` is equal to 2), the following applies:

$$qP = Qp'_{cr} \quad (8-293)$$

The variables `bitDepth`, `bdShift` and `tsShift` are derived as follows:

$$\text{bitDepth} = (\text{cIdx} == 0) ? \text{BitDepth}_Y : \text{BitDepth}_C \quad (8-294)$$

$$\text{bdShift} = \text{Max}(20 - \text{bitDepth}, \text{extended_precision_processing_flag} ? 11 : 0) \quad (8-295)$$

$$\text{tsShift} = 5 + \text{Log2}(nTbS) \quad (8-296)$$

The variable `rotateCoeffs` is derived as follows:

- If all of the following conditions are true, `rotateCoeffs` is set equal to 1:
 - `transform_skip_rotation_enabled_flag` is equal to 1.
 - `nTbS` is equal to 4.
 - `CuPredMode[xTbY][yTbY]` is equal to `MODE_INTRA`.
- Otherwise, `rotateCoeffs` is set equal to 0.

The $(nTbS) \times (nTbS)$ array of residual samples r is derived as follows:

- If `cu_transquant_bypass_flag` is equal to 1, the following applies:
 - If `rotateCoeffs` is equal to 1, the residual sample array values $r[x][y]$ with $x = 0..nTbS - 1$, $y = 0..nTbS - 1$ are derived as follows:

$$r[x][y] = \text{TransCoeffLevel}[xTbY][yTbY][cIdx][nTbS - x - 1][nTbS - y - 1] \quad (8-297)$$

- Otherwise, the $(nTbS) \times (nTbS)$ array r is set equal to the $(nTbS) \times (nTbS)$ array of transform coefficients `TransCoeffLevel[xTbY][yTbY][cIdx]`.
- Otherwise, the following ordered steps apply:
 1. The scaling process for transform coefficients as specified in clause 8.6.3 is invoked with the transform block location (`xTbY`, `yTbY`), the size of the transform block `nTbS`, the colour component variable `cIdx` and the quantization parameter qP as inputs, and the output is an $(nTbS) \times (nTbS)$ array of scaled transform coefficients d .
 2. The $(nTbS) \times (nTbS)$ array of residual samples r is derived as follows:
 - If `transform_skip_flag[xTbY][yTbY][cIdx]` is equal to 1, the residual sample array values $r[x][y]$ with $x = 0..nTbS - 1$, $y = 0..nTbS - 1$ are derived as follows:

$$r[x][y] = (\text{rotateCoeffs} ? d[nTbS - x - 1][nTbS - y - 1] : d[x][y]) << \text{tsShift} \quad (8-298)$$

- Otherwise (transform_skip_flag[xTbY][yTbY][cIdx] is equal to 0), the transformation process for scaled transform coefficients as specified in clause 8.6.4 is invoked with the transform block location (xTbY, yTbY), the size of the transform block nTbS, the colour component variable cIdx and the (nTbS)x(nTbS) array of scaled transform coefficients d as inputs, and the output is an (nTbS)x(nTbS) array of residual samples r.

3. The residual sample values $r[x][y]$ with $x = 0..nTbS - 1$, $y = 0..nTbS - 1$ are modified as follows:

$$r[x][y] = (r[x][y] + (1 \ll (bdShift - 1))) \gg bdShift \quad (8-299)$$

8.6.3 Scaling process for transform coefficients

Inputs to this process are:

- a luma location (xTbY, yTbY) specifying the top-left sample of the current luma transform block relative to the top-left luma sample of the current picture,
- a variable nTbS specifying the size of the current transform block,
- a variable cIdx specifying the colour component of the current block,
- a variable qP specifying the quantization parameter.

Output of this process is the (nTbS)x(nTbS) array d of scaled transform coefficients with elements $d[x][y]$.

The variables log2TransformRange, bdShift, coeffMin and coeffMax are derived as follows:

- If cIdx is equal to 0, the following applies:

$$\log2TransformRange = \text{extended_precision_processing_flag} ? \text{Max}(15, \text{BitDepth}_Y + 6) : 15 \quad (8-300)$$

$$bdShift = \text{BitDepth}_Y + \text{Log2}(nTbS) + 10 - \log2TransformRange \quad (8-301)$$

$$\text{coeffMin} = \text{CoeffMin}_Y \quad (8-302)$$

$$\text{coeffMax} = \text{CoeffMax}_Y \quad (8-303)$$

- Otherwise, the following applies:

$$\log2TransformRange = \text{extended_precision_processing_flag} ? \text{Max}(15, \text{BitDepth}_C + 6) : 15 \quad (8-304)$$

$$bdShift = \text{BitDepth}_C + \text{Log2}(nTbS) + 10 - \log2TransformRange \quad (8-305)$$

$$\text{coeffMin} = \text{CoeffMin}_C \quad (8-306)$$

$$\text{coeffMax} = \text{CoeffMax}_C \quad (8-307)$$

The list levelScale[] is specified as levelScale[k] = { 40, 45, 51, 57, 64, 72 } with $k = 0..5$.

For the derivation of the scaled transform coefficients $d[x][y]$ with $x = 0..nTbS - 1$, $y = 0..nTbS - 1$, the following applies:

- The scaling factor $m[x][y]$ is derived as follows:
 - If one or more of the following conditions are true, $m[x][y]$ is set equal to 16:
 - scaling_list_enabled_flag is equal to 0.
 - transform_skip_flag[xTbY][yTbY] is equal to 1 and nTbS is greater than 4.
 - Otherwise, the following applies:

$$m[x][y] = \text{ScalingFactor}[\text{sizeId}][\text{matrixId}][x][y] \quad (8-308)$$

Where sizeId is specified in Table 7-3 for the size of the quantization matrix equal to (nTbS)x(nTbS) and matrixId is specified in Table 7-4 for sizeId, CuPredMode[xTbY][yTbY] and cIdx, respectively.

- The scaled transform coefficient $d[x][y]$ is derived as follows:

$$d[x][y] = \text{Clip3}(\text{coeffMin}, \text{coeffMax}, ((\text{TransCoeffLevel}[xTbY][yTbY][cIdx][x][y] * m[x][y] * \text{levelScale}[qP \% 6] << (qP / 6)) + (1 << (bdShift - 1))) >> bdShift) \quad (8-309)$$

8.6.4 Transformation process for scaled transform coefficients

8.6.4.1 General

Inputs to this process are:

- a luma location (xTbY, yTbY) specifying the top-left sample of the current luma transform block relative to the top-left luma sample of the current picture,
- a variable nTbS specifying the size of the current transform block,
- a variable cIdx specifying the colour component of the current block,
- an (nTbS)x(nTbS) array d of scaled transform coefficients with elements d[x][y].

Output of this process is the (nTbS)x(nTbS) array r of residual samples with elements r[x][y].

The variables coeffMin and coeffMax are derived as follows:

- If cIdx is equal to 0, the following applies:

$$\text{coeffMin} = \text{CoeffMin}_Y \quad (8-310)$$

$$\text{coeffMax} = \text{CoeffMax}_Y \quad (8-311)$$

- Otherwise, the following applies:

$$\text{coeffMin} = \text{CoeffMin}_C \quad (8-312)$$

$$\text{coeffMax} = \text{CoeffMax}_C \quad (8-313)$$

Depending on the values of CuPredMode[xTbY][yTbY], nTbS and cIdx, the variable trType is derived as follows:

- If CuPredMode[xTbY][yTbY] is equal to MODE_INTRA, nTbS is equal to 4 and cIdx is equal to 0, trType is set equal to 1.
- Otherwise, trType is set equal to 0.

The (nTbS)x(nTbS) array r of residual samples is derived by the following ordered steps:

1. Each (vertical) column of scaled transform coefficients d[x][y] with x = 0..nTbS – 1, y = 0..nTbS – 1 is transformed to e[x][y] with x = 0..nTbS – 1, y = 0..nTbS – 1 by invoking the one-dimensional transformation process as specified in clause 8.6.4.2 for each column x = 0..nTbS – 1 with the size of the transform block nTbS, the list d[x][y] with y = 0..nTbS – 1 and the transform type variable trType as inputs, and the output is the list e[x][y] with y = 0..nTbS – 1.

2. The intermediate sample values g[x][y] with x = 0..nTbS – 1, y = 0..nTbS – 1 are derived as follows:

$$g[x][y] = \text{Clip3}(\text{coeffMin}, \text{coeffMax}, (e[x][y] + 64) >> 7) \quad (8-314)$$

3. Each (horizontal) row of the resulting array g[x][y] with x = 0..nTbS – 1, y = 0..nTbS – 1 is transformed to r[x][y] with x = 0..nTbS – 1, y = 0..nTbS – 1 by invoking the one-dimensional transformation process as specified in clause 8.6.4.2 for each row y = 0..nTbS – 1 with the size of the transform block nTbS, the list g[x][y] with x = 0..nTbS – 1 and the transform type variable trType as inputs, and the output is the list r[x][y] with x = 0..nTbS – 1.

8.6.4.2 Transformation process

Inputs to this process are:

- a variable nTbS specifying the sample size of scaled transform coefficients,
- a list of scaled transform coefficients x with elements x[j], with j = 0..nTbS – 1.
- a transform type variable trType

Output of this process is the list of transformed samples y with elements $y[i]$, with $i = 0..nTbS - 1$.

Depending on the value of $trType$, the following applies:

- If $trType$ is equal to 1, the following transform matrix multiplication applies:

$$y[i] = \sum_{j=0}^{nTbS-1} transMatrix[i][j] * x[j] \text{ with } i = 0..nTbS - 1 \quad (8-315)$$

where the transform coefficient array $transMatrix$ is specified as follows:

$$transMatrix = \quad (8-316)$$

```
{
{29  55  74  84}
{74  74   0 -74}
{84 -29 -74  55}
{55 -84  74 -29}
}
```

- Otherwise ($trType$ is equal to 0), the following transform matrix multiplication applies:

$$y[i] = \sum_{j=0}^{nTbS-1} transMatrix[i][j * 2^{5-\log_2(nTbS)}] * x[j] \text{ with } i = 0..nTbS - 1, \quad (8-317)$$

where the transform coefficient array $transMatrix$ is specified as follows:

$$transMatrix[m][n] = transMatrixCol0to15[m][n] \text{ with } m = 0..15, n = 0..31 \quad (8-318)$$

$$transMatrixCol0to15 = \quad (8-319)$$

```

8.6.5 Residual modification process for blocks using a transform bypass

Inputs to this process are:

- a variable mDir specifying the residual modification direction,
- a variable nTbS specifying the transform block size,
- an (nTbS)x(nTbS) array of residual samples r with elements r[x][y].

Output of this process is the modified (nTbS)x(nTbS) array of residual samples.

Depending upon the value of mDir, the (nTbS)x(nTbS) array of samples r is modified as follows:

- If mDir is equal to 0 (horizontal direction), the array values r[x][y] are modified as follows, for x proceeding over the values 1..nTbS – 1 and y = 0..nTbS – 1:

$$r[x][y] += r[x-1][y] \quad (8-322)$$

- Otherwise (vertical direction), the array values r[x][y] are modified as follows, for y proceeding over the values 1..nTbS – 1 and for x = 0..nTbS – 1:

$$r[x][y] += r[x][y-1] \quad (8-323)$$

8.6.6 Residual modification process for transform blocks using cross-component prediction

This process is only invoked when ChromaArrayType is equal to 3.

Inputs to this process are:

- a luma location (xTbY, yTbY) specifying the top-left sample of the current luma transform block relative to the top-left luma sample of the current picture,
- a variable nTbS specifying the transform block size,

- a variable *cIdx* specifying the colour component of the current block,
- an $(nTbS) \times (nTbS)$ array of luma residual samples r_Y with elements $r_Y[x][y]$,
- an $(nTbS) \times (nTbS)$ array of residual samples r with elements $r[x][y]$.

Output of this process is the modified $(nTbS) \times (nTbS)$ array r of residual samples.

The $(nTbS) \times (nTbS)$ array of residual samples r with $x = 0..nTbS - 1$, $y = 0..nTbS - 1$ is modified as follows:

$$r[x][y] += (ResScaleVal[cIdx][xTbY][yTbY] * ((r_Y[x][y] << BitDepth_C) >> BitDepth_Y)) >> 3 \quad (8-324)$$

It is a requirement of bitstream conformance that the luma residual samples $r_Y[x][y]$ shall be in the range of *CoeffMinY* to *CoeffMaxY*, inclusive, and the input residual samples $r[x][y]$ shall be in the range of *CoeffMinC* to *CoeffMaxC*, inclusive.

8.6.7 Picture construction process prior to in-loop filter process

Inputs to this process are:

- a location $(xCurr, yCurr)$ specifying the top-left sample of the current block relative to the top-left sample of the current picture component,
- the variables *nCurrSw* and *nCurrSh* specifying the width and height, respectively, of the current block,
- a variable *cIdx* specifying the colour component of the current block,
- an $(nCurrSw) \times (nCurrSh)$ array *predSamples* specifying the predicted samples of the current block,
- an $(nCurrSw) \times (nCurrSh)$ array *resSamples* specifying the residual samples of the current block.

Depending on the value of the colour component *cIdx*, the following assignments are made:

- If *cIdx* is equal to 0, *recSamples* corresponds to the reconstructed picture sample array S_L and the function *clipCidx1* corresponds to *Clip1Y*.
- Otherwise, if *cIdx* is equal to 1, *recSamples* corresponds to the reconstructed chroma sample array S_{Cb} and the function *clipCidx1* corresponds to *Clip1C*.
- Otherwise (*cIdx* is equal to 2), *recSamples* corresponds to the reconstructed chroma sample array S_{Cr} and the function *clipCidx1* corresponds to *Clip1C*.

The $(nCurrSw) \times (nCurrSh)$ block of the reconstructed sample array *recSamples* at location $(xCurr, yCurr)$ is derived as follows:

$$recSamples[xCurr + i][yCurr + j] = clipCidx1(predSamples[i][j] + resSamples[i][j]) \quad (8-325)$$

with $i = 0..nCurrSw - 1$, $j = 0..nCurrSh - 1$

8.6.8 Residual modification process for blocks using adaptive colour transform

This process is only invoked when *ChromaArrayType* is equal to 3.

8.6.8.1 General

Inputs to this process are:

- a sample location $(xTb0, yTb0)$ specifying the top-left sample of the current block relative to the top left sample of the current picture,
- a variable *log2TrafoSize* specifying the size of the current block,
- a variable *trafoDepth* specifying the hierarchy depth of the current block relative to the coding unit,
- an array *resSampleArrayL* specifying the luma residual samples of the current block,
- an array *resSampleArrayCb* specifying the Cb residual samples of the current block,
- an array *resSampleArrayCr* specifying the Cr residual samples of the current block.

Outputs of this process are the modified arrays `resSampleY`, `resSampleCb` and `resSampleCr` of residual samples of the current block.

Depending on the value of `split_transform_flag[xTb0][yTb0][trafoDepth]`, the following applies:

- If `split_transform_flag[xTb0][yTb0][trafoDepth]` is equal to 1, the following ordered steps apply:
 1. The variables `xTb1` and `yTb1` are derived as follows:
 - The variable `xTb1` is set equal to $xTb0 + (1 \ll (\log_2TrafoSize - 1))$.
 - The variable `yTb1` is set equal to $yTb0 + (1 \ll (\log_2TrafoSize - 1))$.
 2. The residual modification process for blocks using adaptive colour transform as specified in this clause is invoked with the location (`xTb0`, `yTb0`), the variable `log2TrafoSize` set equal to `log2TrafoSize - 1`, the variable `trafoDepth` set equal to `trafoDepth + 1`, the residual sample arrays `resSampeArrayL`, `resSampleArrayCb` and `resSampleArrayCr` as inputs and the output are modified versions of `resSampeArrayL`, `resSampleArrayCb` and `resSampleArrayCr`.
 3. The residual modification process for blocks using adaptive colour transform as specified in this clause is invoked with the location (`xTb1`, `yTb0`), the variable `log2TrafoSize` set equal to `log2TrafoSize - 1`, the variable `trafoDepth` set equal to `trafoDepth + 1`, the residual sample arrays `resSampeArrayL`, `resSampleArrayCb` and `resSampleArrayCr` as inputs and the output are modified versions of `resSampeArrayL`, `resSampleArrayCb` and `resSampleArrayCr`.
 4. The residual modification process for blocks using adaptive colour transform as specified in this clause is invoked with the location (`xTb0`, `yTb1`), the variable `log2TrafoSize` set equal to `log2TrafoSize - 1`, the variable `trafoDepth` set equal to `trafoDepth + 1`, the residual sample arrays `resSampeArrayL`, `resSampleArrayCb` and `resSampleArrayCr` as inputs and the output are modified versions of `resSampeArrayL`, `resSampleArrayCb` and `resSampleArrayCr`.
 5. The residual modification process for blocks using adaptive colour transform as specified in this clause is invoked with the location (`xTb1`, `yTb1`), the variable `log2TrafoSize` set equal to `log2TrafoSize - 1`, the variable `trafoDepth` set equal to `trafoDepth + 1`, the residual sample arrays `resSampeArrayL`, `resSampleArrayCb` and `resSampleArrayCr` as inputs and the output are modified versions of `resSampeArrayL`, `resSampleArrayCb` and `resSampleArrayCr`.
- Otherwise (`split_transform_flag[xTb0][yTb0][trafoDepth]` is equal to 0), the following ordered steps apply:
 1. The variable `nTbS` specifying the current transform block is set equal to $(1 \ll \log_2TrafoSize)$.
 2. The variable `nCbS` specifying the size of the current coding block is derived as $nCbS = 1 \ll (\log_2TrafoSize + trafoDepth)$.
 3. The sample location (`xTbInCb`, `yTbInCb`) specifying the top-left sample of the current transform block relative to the top-left sample of the current coding block are derived as $xTbInCb = xTb0 \& (nCbS - 1)$ and $yTbInCb = yTb0 \& (nCbS - 1)$.

When `tu_residual_act_flag[xTb0][yTb0]` is equal to 1, the adaptive colour transformation process as specified in clause 8.6.8.2 is invoked with the sample location (`xTb0`, `yTb0`) set to (`xTbInCb`, `yTbInCb`), the variable `blkSize` set equal to `nTbS`, the array `rY` set equal to `resSampleArrayL`, the array `rCb` set equal to `resSampleArrayCb`, and the array `rCr` set equal to `resSampleArrayCr` as inputs, and the outputs are modified versions of the three residual sample arrays.

8.6.8.2 Adaptive colour transformation process

Inputs to this process are:

- a sample location (`xTb0`, `yTb0`) specifying the top-left sample of the current transform block relative to the top left sample of the current coding block,
- a variable `blkSize` specifying the block size of the transform block to be modified,
- an array of luma residual samples `rY` of the current coding block,
- an array of chroma residual samples `rCb` of the current coding block,
- an array of chroma residual samples `rCr` of the current coding block.

Outputs of this process are:

- a modified array `rY` of luma residual samples,

- a modified array rCb of chroma residual samples,
- a modified array rCr of chroma residual samples.

The arrays of residual samples rY, rCb and rCr with $x = x_{Tb0}..x_{Tb0} + blkSize - 1$, $y = y_{Tb0}..y_{Tb0} + blkSize - 1$ are modified as follows:

$$rY[x][y] = Clip3(CoeffMinY, CoeffMaxY, rY[x][y]) \quad (8-326)$$

$$rCb[x][y] = Clip3(CoeffMinC, CoeffMaxC, rCb[x][y]) \quad (8-327)$$

$$rCr[x][y] = Clip3(CoeffMinC, CoeffMaxC, rCr[x][y]) \quad (8-328)$$

- When cu_transquant_bypass_flag is equal to 0, the following ordered steps apply:

1. The variables deltaBDY and deltaBDC are derived as follows:

$$deltaBDY = Max(BitDepth_Y, BitDepth_C) - BitDepth_Y \quad (8-329)$$

$$deltaBDC = Max(BitDepth_Y, BitDepth_C) - BitDepth_C \quad (8-330)$$

$$offsetBDY = deltaBDY ? 1 << (deltaBDY - 1) : 0 \quad (8-331)$$

$$offsetBDC = deltaBDC ? 1 << (deltaBDC - 1) : 0 \quad (8-332)$$

2. Residual samples rY[x][y], rCb[x][y] and rCr[x][y] are modified as follows:

$$rY[x][y] = rY[x][y] << deltaBDY \quad (8-333)$$

$$rCb[x][y] = rCb[x][y] << (deltaBDC + 1) \quad (8-334)$$

$$rCr[x][y] = rCr[x][y] << (deltaBDC + 1) \quad (8-335)$$

- Residual samples rY[x][y], rCb[x][y] and rCr[x][y] are modified as follows:

$$tmp = rY[x][y] - (rCb[x][y] >> 1) \quad (8-336)$$

$$rY[x][y] = tmp + rCb[x][y] \quad (8-337)$$

$$rCb[x][y] = tmp - (rCr[x][y] >> 1) \quad (8-338)$$

$$rCr[x][y] += rCb[x][y] \quad (8-339)$$

- When cu_transquant_bypass_flag is equal to 0, the following applies:

$$rY[x][y] = (rY[x][y] + offsetBDY) >> deltaBDY \quad (8-340)$$

$$rCb[x][y] = (rCb[x][y] + offsetBDC) >> deltaBDC \quad (8-341)$$

$$rCr[x][y] = (rCr[x][y] + offsetBDC) >> deltaBDC \quad (8-342)$$

8.7 In-loop filter process

8.7.1 General

This clause specifies the application of two in-loop filters. When the in-loop filter process is specified as optional in Annex A, the application of either or both of these filters is optional.

The two in-loop filters, namely deblocking filter and sample adaptive offset filter, are applied as specified by the following ordered steps:

1. For the deblocking filter, the following applies:

- The deblocking filter process as specified in clause 8.7.2 is invoked with the reconstructed picture sample array S_L and, when ChromaArrayType is not equal to 0, the arrays S_{Cb} and S_{Cr} as inputs, and the modified reconstructed picture sample array S'_L and, when ChromaArrayType is not equal to 0, the arrays S'_{Cb} and S'_{Cr} after deblocking as outputs.
 - The array S'_L and, when ChromaArrayType is not equal to 0, the arrays S'_{Cb} and S'_{Cr} are assigned to the array S_L and, when ChromaArrayType is not equal to 0, the arrays S_{Cb} and S_{Cr} (which represent the decoded picture), respectively.
2. When sample_adaptive_offset_enabled_flag is equal to 1, the following applies:
- The sample adaptive offset process as specified in clause 8.7.3 is invoked with the reconstructed picture sample array S_L and, when ChromaArrayType is not equal to 0, the arrays S_{Cb} and S_{Cr} as inputs, and the modified reconstructed picture sample array S'_L and, when ChromaArrayType is not equal to 0, the arrays S'_{Cb} and S'_{Cr} after sample adaptive offset as outputs.
 - The array S'_L and, when ChromaArrayType is not equal to 0, the arrays S'_{Cb} and S'_{Cr} are assigned to the array S_L and, when ChromaArrayType is not equal to 0, the arrays S_{Cb} and S_{Cr} (which represent the decoded picture), respectively.

8.7.2 Deblocking filter process

8.7.2.1 General

Inputs to this process are the reconstructed picture prior to deblocking, i.e., the array $recPicture_L$ and, when ChromaArrayType is not equal to 0, the arrays $recPicture_{Cb}$ and $recPicture_{Cr}$.

Outputs of this process are the modified reconstructed picture after deblocking, i.e., the array $recPicture_L$ and, when ChromaArrayType is not equal to 0, the arrays $recPicture_{Cb}$ and $recPicture_{Cr}$.

The vertical edges in a picture are filtered first. Then the horizontal edges in a picture are filtered with samples modified by the vertical edge filtering process as input. The vertical and horizontal edges in the CTBs of each CTU are processed separately on a coding unit basis. The vertical edges of the coding blocks in a coding unit are filtered starting with the edge on the left-hand side of the coding blocks proceeding through the edges towards the right-hand side of the coding blocks in their geometrical order. The horizontal edges of the coding blocks in a coding unit are filtered starting with the edge on the top of the coding blocks proceeding through the edges towards the bottom of the coding blocks in their geometrical order.

NOTE – Although the filtering process is specified on a picture basis in this Specification, the filtering process can be implemented on a coding unit basis with an equivalent result, provided the decoder properly accounts for the processing dependency order so as to produce the same output values.

The deblocking filter process is applied to all prediction block edges and transform block edges of a picture, except the following types of edges:

- Edges that are at the boundary of the picture,
- Edges that coincide with tile boundaries when loop_filter_across_tiles_enabled_flag is equal to 0,
- Edges that coincide with upper or left boundaries of slices with slice_loop_filter_across_slices_enabled_flag equal to 0 or slice_deblocking_filter_disabled_flag equal to 1,
- Edges within slices with slice_deblocking_filter_disabled_flag equal to 1,
- Edges that do not correspond to 8x8 sample grid boundaries of the considered component,
- Edges within chroma components for which both sides of the edge use inter prediction,
- Edges of chroma transform blocks that are not edges of the associated transform unit.

The edge type, vertical or horizontal, is represented by the variable edgeType as specified in Table 8-11.

Table 8-11 – Name of association to edgeType

edgeType	Name of edgeType
0 (vertical edge)	EDGE_VER
1 (horizontal edge)	EDGE_HOR

When slice_deblocking_filter_disabled_flag of the current slice is equal to 0, for each coding unit with luma coding block size log2CbSize and location of top-left sample of the luma coding block (x_{Cb} , y_{Cb}), the vertical edges are filtered by the following ordered steps:

1. The luma coding block size $nCbS$ is set equal to $1 \ll \log_2 CbSize$.
2. The variable `filterLeftCbEdgeFlag` is derived as follows:
 - If one or more of the following conditions are true, `filterLeftCbEdgeFlag` is set equal to 0:
 - The left boundary of the current luma coding block is the left boundary of the picture.
 - The left boundary of the current luma coding block is the left boundary of the tile and `loop_filter_across_tiles_enabled_flag` is equal to 0.
 - The left boundary of the current luma coding block is the left boundary of the slice and `slice_loop_filter_across_slices_enabled_flag` is equal to 0.
 - Otherwise, `filterLeftCbEdgeFlag` is set equal to 1.
3. All elements of the two-dimensional $(nCbS) \times (nCbS)$ array `verEdgeFlags` are initialized to be equal to zero.
4. The derivation process of transform block boundary specified in clause 8.7.2.2 is invoked with the luma location (xCb, yCb) , the luma location $(xB0, yB0)$ set equal to $(0, 0)$, the transform block size $\log_2 TrafoSize$ set equal to $\log_2 CbSize$, the variable `trafoDepth` set equal to 0, the variable `filterLeftCbEdgeFlag`, the array `verEdgeFlags` and the variable `edgeType` set equal to `EDGE_VER` as inputs, and the modified array `verEdgeFlags` as output.
5. The derivation process of prediction block boundary specified in clause 8.7.2.3 is invoked with the luma coding block size $\log_2 CbSize$, the prediction partition mode `PartMode`, the array `verEdgeFlags` and the variable `edgeType` set equal to `EDGE_VER` as inputs, and the modified array `verEdgeFlags` as output.
6. The derivation process of the boundary filtering strength specified in clause 8.7.2.4 is invoked with the reconstructed luma picture sample array prior to deblocking `recPictureL`, the luma location (xCb, yCb) , the luma coding block size $\log_2 CbSize$, the variable `edgeType` set equal to `EDGE_VER` and the array `verEdgeFlags` as inputs, and an $(nCbS) \times (nCbS)$ array `verBs` as output.
7. The vertical edge filtering process for a coding unit as specified in clause 8.7.2.5.1 is invoked with the reconstructed picture prior to deblocking, i.e., the array `recPictureL` and, when `ChromaArrayType` is not equal to 0, the arrays `recPictureCb` and `recPictureCr`, the luma location (xCb, yCb) , the luma coding block size $\log_2 CbSize$ and the array `verBs` as inputs, and the modified reconstructed picture, i.e., the array `recPictureL` and, when `ChromaArrayType` is not equal to 0, the arrays `recPictureCb` and `recPictureCr`, as output.

When `slice_deblocking_filter_disabled_flag` of the current slice is equal to 0, for each coding unit with luma coding block size $\log_2 CbSize$ and location of top-left sample of the luma coding block (xCb, yCb) , the horizontal edges are filtered by the following ordered steps:

1. The luma coding block size $nCbS$ is set equal to $1 \ll \log_2 CbSize$.
2. The variable `filterTopCbEdgeFlag` is derived as follows:
 - If one or more of the following conditions are true, the variable `filterTopCbEdgeFlag` is set equal to 0:
 - The top boundary of the current luma coding block is the top boundary of the picture.
 - The top boundary of the current luma coding block is the top boundary of the tile and `loop_filter_across_tiles_enabled_flag` is equal to 0.
 - The top boundary of the current luma coding block is the top boundary of the slice and `slice_loop_filter_across_slices_enabled_flag` is equal to 0.
 - Otherwise, the variable `filterTopCbEdgeFlag` is set equal to 1.
3. All elements of the two-dimensional $(nCbS) \times (nCbS)$ array `horEdgeFlags` are initialized to zero.
4. The derivation process of transform block boundary specified in clause 8.7.2.2 is invoked with the luma location (xCb, yCb) , the luma location $(xB0, yB0)$ set equal to $(0, 0)$, the transform block size $\log_2 TrafoSize$ set equal to $\log_2 CbSize$, the variable `trafoDepth` set equal to 0, the variable `filterTopCbEdgeFlag`, the array `horEdgeFlags` and the variable `edgeType` set equal to `EDGE_HOR` as inputs, and the modified array `horEdgeFlags` as output.
5. The derivation process of prediction block boundary specified in clause 8.7.2.3 is invoked with the luma coding block size $\log_2 CbSize$, the prediction partition mode `PartMode`, the array `horEdgeFlags` and the variable `edgeType` set equal to `EDGE_HOR` as inputs, and the modified array `horEdgeFlags` as output.
6. The derivation process of the boundary filtering strength specified in clause 8.7.2.4 is invoked with the reconstructed luma picture sample array prior to deblocking `recPictureL`, the luma location (xCb, yCb) , the luma coding block size $\log_2 CbSize$, the variable `edgeType` set equal to `EDGE_HOR` and the array `horEdgeFlags` as inputs, and an $(nCbS) \times (nCbS)$ array `horBs` as output.

7. The horizontal edge filtering process for a coding unit as specified in clause 8.7.2.5.2 is invoked with the modified reconstructed picture, i.e., the array recPicture_L and, when ChromaArrayType is not equal to 0, the arrays recPicture_{Cb} and recPicture_{Cr} , the luma location (x_{Cb}, y_{Cb}) , the luma coding block size $\log_2\text{CbSize}$, and the array horBs as inputs and the modified reconstructed picture, i.e., the array recPicture_L and, when ChromaArrayType is not equal to 0, the arrays recPicture_{Cb} and recPicture_{Cr} , as output.

8.7.2.2 Derivation process of transform block boundary

Inputs to this process are:

- a luma location (x_{Cb}, y_{Cb}) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a luma location (x_{B0}, y_{B0}) specifying the top-left sample of the current luma block relative to the top-left sample of the current luma coding block,
- a variable $\log_2\text{TrafoSize}$ specifying the size of the current block,
- a variable trafoDepth ,
- a variable filterEdgeFlag ,
- a two-dimensional $(n_{CbS}) \times (n_{CbS})$ array edgeFlags ,
- a variable edgeType specifying whether a vertical (EDGE_VER) or a horizontal (EDGE_HOR) edge is filtered.

Output of this process is the modified two-dimensional $(n_{CbS}) \times (n_{CbS})$ array edgeFlags .

Depending on the value of $\text{split_transform_flag}[x_{Cb} + x_{B0}][y_{Cb} + y_{B0}][\text{trafoDepth}]$, the following applies:

- If $\text{split_transform_flag}[x_{Cb} + x_{B0}][y_{Cb} + y_{B0}][\text{trafoDepth}]$ is equal to 1, the following ordered steps apply:
 1. The variables x_{B1} and y_{B1} are derived as follows:
 - The variable x_{B1} is set equal to $x_{B0} + (1 \ll (\log_2\text{TrafoSize} - 1))$.
 - The variable y_{B1} is set equal to $y_{B0} + (1 \ll (\log_2\text{TrafoSize} - 1))$.
 2. The derivation process of transform block boundary as specified in this clause is invoked with the luma location (x_{Cb}, y_{Cb}) , the luma location (x_{B0}, y_{B0}) , the variable $\log_2\text{TrafoSize}$ set equal to $\log_2\text{TrafoSize} - 1$, the variable trafoDepth set equal to $\text{trafoDepth} + 1$, the variable filterEdgeFlag , the array edgeFlags and the variable edgeType as inputs, and the output is the modified version of array edgeFlags .
 3. The derivation process of transform block boundary as specified in this clause is invoked with the luma location (x_{Cb}, y_{Cb}) , the luma location (x_{B1}, y_{B0}) , the variable $\log_2\text{TrafoSize}$ set equal to $\log_2\text{TrafoSize} - 1$, the variable trafoDepth set equal to $\text{trafoDepth} + 1$, the variable filterEdgeFlag , the array edgeFlags and the variable edgeType as inputs, and the output is the modified version of array edgeFlags .
 4. The derivation process of transform block boundary as specified in this clause is invoked with the luma location (x_{Cb}, y_{Cb}) , the luma location (x_{B0}, y_{B1}) , the variable $\log_2\text{TrafoSize}$ set equal to $\log_2\text{TrafoSize} - 1$, the variable trafoDepth set equal to $\text{trafoDepth} + 1$, the variable filterEdgeFlag , the array edgeFlags and the variable edgeType as inputs, and the output is the modified version of array edgeFlags .
 5. The derivation process of transform block boundary as specified in this clause is invoked with the luma location (x_{Cb}, y_{Cb}) , the luma location (x_{B1}, y_{B1}) , the variable $\log_2\text{TrafoSize}$ set equal to $\log_2\text{TrafoSize} - 1$, the variable trafoDepth set equal to $\text{trafoDepth} + 1$, the variable filterEdgeFlag , the array edgeFlags and the variable edgeType as inputs, and the output is the modified version of array edgeFlags .
- Otherwise ($\text{split_transform_flag}[x_{Cb} + x_{B0}][y_{Cb} + y_{B0}][\text{trafoDepth}]$ is equal to 0), the following applies:
 - If edgeType is equal to EDGE_VER , the value of $\text{edgeFlags}[x_{B0}][y_{B0} + k]$ for $k = 0..(1 \ll \log_2\text{TrafoSize}) - 1$ is derived as follows:
 - If x_{B0} is equal to 0, $\text{edgeFlags}[x_{B0}][y_{B0} + k]$ is set equal to filterEdgeFlag .
 - Otherwise, $\text{edgeFlags}[x_{B0}][y_{B0} + k]$ is set equal to 1.
 - Otherwise (edgeType is equal to EDGE_HOR), the value of $\text{edgeFlags}[x_{B0} + k][y_{B0}]$ for $k = 0..(1 \ll \log_2\text{TrafoSize}) - 1$ is derived as follows:
 - If y_{B0} is equal to 0, $\text{edgeFlags}[x_{B0} + k][y_{B0}]$ is set equal to filterEdgeFlag .
 - Otherwise, $\text{edgeFlags}[x_{B0} + k][y_{B0}]$ is set equal to 1.

8.7.2.3 Derivation process of prediction block boundary

Inputs to this process are:

- a variable $\log_2\text{CbSize}$ specifying the luma coding block size,
- a prediction partition mode PartMode ,
- a two-dimensional $(n\text{CbS}) \times (n\text{CbS})$ array edgeFlags ,
- a variable edgeType specifying whether a vertical (EDGE_VER) or a horizontal (EDGE_HOR) edge is filtered.

Output of this process is the modified two-dimensional $(n\text{CbS}) \times (n\text{CbS})$ array edgeFlags .

Depending on the values of edgeType and PartMode , the following applies for $k = 0..(1 \ll \log_2\text{CbSize}) - 1$:

- If edgeType is equal to EDGE_VER , the following applies:
 - When PartMode is equal to PART_Nx2N or PART_NxN , $\text{edgeFlags}[1 \ll (\log_2\text{CbSize} - 1)][k]$ is set equal to 1.
 - When PartMode is equal to PART_nLx2N , $\text{edgeFlags}[1 \ll (\log_2\text{CbSize} - 2)][k]$ is set equal to 1.
 - When PartMode is equal to PART_nRx2N , $\text{edgeFlags}[3 * (1 \ll (\log_2\text{CbSize} - 2))][k]$ is set equal to 1.
- Otherwise (edgeType is equal to EDGE_HOR), the following applies:
 - When PartMode is equal to PART_2NxN or PART_NxN , $\text{edgeFlags}[k][1 \ll (\log_2\text{CbSize} - 1)]$ is set equal to 1.
 - When PartMode is equal to PART_2NxN_U , $\text{edgeFlags}[k][1 \ll (\log_2\text{CbSize} - 2)]$ is set equal to 1.
 - When PartMode is equal to PART_2NxN_D , $\text{edgeFlags}[k][3 * (1 \ll (\log_2\text{CbSize} - 2))]$ is set equal to 1.

8.7.2.4 Derivation process of boundary filtering strength

Inputs to this process are:

- a luma picture sample array recPicture_L ,
- a luma location $(x\text{Cb}, y\text{Cb})$ specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a variable $\log_2\text{CbSize}$ specifying the size of the current luma coding block,
- a variable edgeType specifying whether a vertical (EDGE_VER) or a horizontal (EDGE_HOR) edge is filtered,
- a two-dimensional $(n\text{CbS}) \times (n\text{CbS})$ array edgeFlags .

Output of this process is a two-dimensional $(n\text{CbS}) \times (n\text{CbS})$ array $b\text{S}$ specifying the boundary filtering strength.

The variables $x\text{D}_i$, $y\text{D}_j$, $x\text{N}$ and $y\text{N}$ are derived as follows:

- If edgeType is equal to EDGE_VER , $x\text{D}_i$ is set equal to $(i \ll 3)$, $y\text{D}_j$ is set equal to $(j \ll 2)$, $x\text{N}$ is set equal to $(1 \ll (\log_2\text{CbSize} - 3)) - 1$ and $y\text{N}$ is set equal to $(1 \ll (\log_2\text{CbSize} - 2)) - 1$.
- Otherwise (edgeType is equal to EDGE_HOR), $x\text{D}_i$ is set equal to $(i \ll 2)$, $y\text{D}_j$ is set equal to $(j \ll 3)$, $x\text{N}$ is set equal to $(1 \ll (\log_2\text{CbSize} - 2)) - 1$ and $y\text{N}$ is set equal to $(1 \ll (\log_2\text{CbSize} - 3)) - 1$.

For $x\text{D}_i$ with $i = 0..x\text{N}$ and $y\text{D}_j$ with $j = 0..y\text{N}$, the following applies:

- If $\text{edgeFlags}[x\text{D}_i][y\text{D}_j]$ is equal to 0, the variable $b\text{S}[x\text{D}_i][y\text{D}_j]$ is set equal to 0.
- Otherwise ($\text{edgeFlags}[x\text{D}_i][y\text{D}_j]$ is equal to 1), the following applies:
 - The sample values p_0 and q_0 are derived as follows:
 - If edgeType is equal to EDGE_VER , p_0 is set equal to $\text{recPicture}_L[x\text{Cb} + x\text{D}_i - 1][y\text{Cb} + y\text{D}_j]$ and q_0 is set equal to $\text{recPicture}_L[x\text{Cb} + x\text{D}_i][y\text{Cb} + y\text{D}_j]$.
 - Otherwise (edgeType is equal to EDGE_HOR), p_0 is set equal to $\text{recPicture}_L[x\text{Cb} + x\text{D}_i][y\text{Cb} + y\text{D}_j - 1]$ and q_0 is set equal to $\text{recPicture}_L[x\text{Cb} + x\text{D}_i][y\text{Cb} + y\text{D}_j]$.
 - The variable $b\text{S}[x\text{D}_i][y\text{D}_j]$ is derived as follows:
 - If the sample p_0 or q_0 is in the luma coding block of a coding unit coded with intra prediction mode, $b\text{S}[x\text{D}_i][y\text{D}_j]$ is set equal to 2.

- Otherwise, if the block edge is also a transform block edge and the sample p_0 or q_0 is in a luma transform block which contains one or more non-zero transform coefficient levels, $bS[xD_i][yD_j]$ is set equal to 1.
- Otherwise, if one or more of the following conditions are true, $bS[xD_i][yD_j]$ is set equal to 1:
 - For the prediction of the luma prediction block containing the sample p_0 different reference pictures or a different number of motion vectors are used than for the prediction of the luma prediction block containing the sample q_0 .

NOTE 1 – The determination of whether the reference pictures used for the two luma prediction blocks are the same or different is based only on which pictures are referenced, without regard to whether a prediction is formed using an index into reference picture list 0 or an index into reference picture list 1, and also without regard to whether the index position within a reference picture list is different.

NOTE 2 – The number of motion vectors that are used for the prediction of a luma prediction block with top-left luma sample covering (xPb, yPb) , is equal to $PredFlagL0[xPb][yPb] + PredFlagL1[xPb][yPb]$.
 - One motion vector is used to predict the luma prediction block containing the sample p_0 and one motion vector is used to predict the luma prediction block containing the sample q_0 , and the absolute difference between the horizontal or vertical component of the motion vectors used is greater than or equal to 4 in units of quarter luma samples.
 - Two motion vectors and two different reference pictures are used to predict the luma prediction block containing the sample p_0 , two motion vectors for the same two reference pictures are used to predict the luma prediction block containing the sample q_0 and the absolute difference between the horizontal or vertical component of the two motion vectors used in the prediction of the two luma prediction blocks for the same reference picture is greater than or equal to 4 in units of quarter luma samples.
 - Two motion vectors for the same reference picture are used to predict the luma prediction block containing the sample p_0 , two motion vectors for the same reference picture are used to predict the luma prediction block containing the sample q_0 and both of the following conditions are true:
 - The absolute difference between the horizontal or vertical component of list 0 motion vectors used in the prediction of the two luma prediction blocks is greater than or equal to 4 in quarter luma samples, or the absolute difference between the horizontal or vertical component of the list 1 motion vectors used in the prediction of the two luma prediction blocks is greater than or equal to 4 in units of quarter luma samples.
 - The absolute difference between the horizontal or vertical component of list 0 motion vector used in the prediction of the luma prediction block containing the sample p_0 and the list 1 motion vector used in the prediction of the luma prediction block containing the sample q_0 is greater than or equal to 4 in units of quarter luma samples, or the absolute difference between the horizontal or vertical component of the list 1 motion vector used in the prediction of the luma prediction block containing the sample p_0 and list 0 motion vector used in the prediction of the luma prediction block containing the sample q_0 is greater than or equal to 4 in units of quarter luma samples.
- Otherwise, the variable $bS[xD_i][yD_j]$ is set equal to 0.

8.7.2.5 Edge filtering process

8.7.2.5.1 Vertical edge filtering process

Inputs to this process are:

- the picture sample array $recPicture_L$ and, when $ChromaArrayType$ is not equal to 0, the arrays $recPicture_{Cb}$ and $recPicture_{Cr}$,
- a luma location (xCb, yCb) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a variable $log2CbSize$ specifying the size of the current luma coding block,
- an array bS specifying the boundary filtering strength.

Outputs of this process are the modified picture sample array $recPicture_L$ and, when $ChromaArrayType$ is not equal to 0, the arrays $recPicture_{Cb}$ and $recPicture_{Cr}$.

The filtering process for edges in the luma coding block of the current coding unit consists of the following ordered steps:

1. The variable nD is set equal to $1 \ll (\log_2 CbSize - 3)$.
2. For xD_k equal to $k \ll 3$ with $k = 0..nD - 1$ and yD_m equal to $m \ll 2$ with $m = 0..nD * 2 - 1$, the following applies:
 - When $bS[xD_k][yD_m]$ is greater than 0, the following ordered steps apply:
 - a. The decision process for luma block edges as specified in clause 8.7.2.5.3 is invoked with the luma picture sample array $recPicture_L$, the location of the luma coding block (xCb, yCb) , the luma location of the block (xD_k, yD_m) , a variable $edgeType$ set equal to $EDGE_VER$ and the boundary filtering strength $bS[xD_k][yD_m]$ as inputs, and the decisions dE , dEp and dEq , and the variables β and t_c as outputs.
 - b. The filtering process for luma block edges as specified in clause 8.7.2.5.4 is invoked with the luma picture sample array $recPicture_L$, the location of the luma coding block (xCb, yCb) , the luma location of the block (xD_k, yD_m) , a variable $edgeType$ set equal to $EDGE_VER$, the decisions dE , dEp and dEq , and the variables β and t_c as inputs, and the modified luma picture sample array $recPicture_L$ as output.

When $ChromaArrayType$ is not equal to 0, the following applies.

The filtering process for edges in the chroma coding blocks of current coding unit consists of the following ordered steps:

1. The variable nD is set equal to $1 \ll (\log_2 CbSize - 3)$.
2. The variable $edgeSpacing$ is set equal to $8 / SubWidthC$.
3. The variable $edgeSections$ is set equal to $nD * (2 / SubHeightC)$.
4. For xD_k equal to $k * edgeSpacing$ with $k = 0..nD - 1$ and yD_m equal to $m \ll 2$ with $m = 0..edgeSections - 1$, the following applies:
 - When $bS[xD_k * SubWidthC][yD_m * SubHeightC]$ is equal to 2 and $((xCb / SubWidthC + xD_k) \gg 3) \ll 3$ is equal to $xCb / SubWidthC + xD_k$, the following ordered steps apply:
 - a. The filtering process for chroma block edges as specified in clause 8.7.2.5.5 is invoked with the chroma picture sample array $recPicture_{Cb}$, the location of the chroma coding block $(xCb / SubWidthC, yCb / SubHeightC)$, the chroma location of the block (xD_k, yD_m) , a variable $edgeType$ set equal to $EDGE_VER$ and a variable $cQpPicOffset$ set equal to $pps_cb_qp_offset$ as inputs, and the modified chroma picture sample array $recPicture_{Cb}$ as output.
 - b. The filtering process for chroma block edges as specified in clause 8.7.2.5.5 is invoked with the chroma picture sample array $recPicture_{Cr}$, the location of the chroma coding block $(xCb / SubWidthC, yCb / SubHeightC)$, the chroma location of the block (xD_k, yD_m) , a variable $edgeType$ set equal to $EDGE_VER$ and a variable $cQpPicOffset$ set equal to $pps_cr_qp_offset$ as inputs, and the modified chroma picture sample array $recPicture_{Cr}$ as output.

8.7.2.5.2 Horizontal edge filtering process

Inputs to this process are:

- the picture sample array $recPicture_L$ and, when $ChromaArrayType$ is not equal to 0, the arrays $recPicture_{Cb}$ and $recPicture_{Cr}$,
- a luma location (xCb, yCb) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a variable $\log_2 CbSize$ specifying the size of the current luma coding block,
- an array bS specifying the boundary filtering strength.

Outputs of this process are the modified picture sample array $recPicture_L$ and, when $ChromaArrayType$ is not equal to 0, the arrays $recPicture_{Cb}$ and $recPicture_{Cr}$.

The filtering process for edges in the luma coding block of the current coding unit consists of the following ordered steps:

1. The variable nD is set equal to $1 \ll (\log_2 CbSize - 3)$.
2. For yD_m equal to $m \ll 3$ with $m = 0..nD - 1$ and xD_k equal to $k \ll 2$ with $k = 0..nD * 2 - 1$, the following applies:
 - When $bS[xD_k][yD_m]$ is greater than 0, the following ordered steps apply:

- a. The decision process for luma block edges as specified in clause 8.7.2.5.3 is invoked with the luma picture sample array recPicture_L , the location of the luma coding block (x_{Cb}, y_{Cb}), the luma location of the block (x_{D_k}, y_{D_m}), a variable edgeType set equal to EDGE_HOR and the boundary filtering strength $\text{bS}[x_{D_k}][y_{D_m}]$ as inputs, and the decisions dE , dEp and dEq , and the variables β and t_C as outputs.
- b. The filtering process for luma block edges as specified in clause 8.7.2.5.4 is invoked with the luma picture sample array recPicture_L , the location of the luma coding block (x_{Cb}, y_{Cb}), the luma location of the block (x_{D_k}, y_{D_m}), a variable edgeType set equal to EDGE_HOR , the decisions dEp , dEp and dEq , and the variables β and t_C as inputs, and the modified luma picture sample array recPicture_L as output.

When ChromaArrayType is not equal to 0, the following applies.

The filtering process for edges in the chroma coding blocks of current coding unit consists of the following ordered steps:

1. The variable nD is set equal to $1 \ll (\log_2 \text{CbSize} - 3)$.
2. The variable edgeSpacing is set equal to $8 / \text{SubHeightC}$.
3. The variable edgeSections is set equal to $nD * (2 / \text{SubWidthC})$.
4. For y_{D_m} equal to $m * \text{edgeSpacing}$ with $m = 0..nD - 1$ and x_{D_k} equal to $k \ll 2$ with $k = 0..\text{edgeSections} - 1$, the following applies:
 - When $\text{bS}[x_{D_k} * \text{SubWidthC}][y_{D_m} * \text{SubHeightC}]$ is equal to 2 and $((y_{Cb} / \text{SubHeightC} + y_{D_m}) \gg 3) \ll 3$ is equal to $y_{Cb} / \text{SubHeightC} + y_{D_m}$, the following ordered steps apply:
 - a. The filtering process for chroma block edges as specified in clause 8.7.2.5.5 is invoked with the chroma picture sample array recPicture_{Cb} , the location of the chroma coding block ($x_{Cb} / \text{SubWidthC}, y_{Cb} / \text{SubHeightC}$), the chroma location of the block (x_{D_k}, y_{D_m}), a variable edgeType set equal to EDGE_HOR and a variable cQpPicOffset set equal to pps_cb_qp_offset as inputs, and the modified chroma picture sample array recPicture_{Cb} as output.
 - b. The filtering process for chroma block edges as specified in clause 8.7.2.5.5 is invoked with the chroma picture sample array recPicture_{Cr} , the location of the chroma coding block ($x_{Cb} / \text{SubWidthC}, y_{Cb} / \text{SubHeightC}$), the chroma location of the block (x_{D_k}, y_{D_m}), a variable edgeType set equal to EDGE_HOR and a variable cQpPicOffset set equal to pps_cr_qp_offset as inputs, and the modified chroma picture sample array recPicture_{Cr} as output.

8.7.2.5.3 Decision process for luma block edges

Inputs to this process are:

- a luma picture sample array recPicture_L ,
- a luma location (x_{Cb}, y_{Cb}) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a luma location (x_{Bl}, y_{Bl}) specifying the top-left sample of the current luma block relative to the top-left sample of the current luma coding block,
- a variable edgeType specifying whether a vertical (EDGE_VER) or a horizontal (EDGE_HOR) edge is filtered,
- a variable bS specifying the boundary filtering strength.

Outputs of this process are:

- the variables dE , dEp and dEq containing decisions,
- the variables β and t_C .

If edgeType is equal to EDGE_VER , the sample values $p_{i,k}$ and $q_{i,k}$ with $i = 0..3$ and $k = 0$ and 3 are derived as follows:

$$q_{i,k} = \text{recPicture}_L[x_{Cb} + x_{Bl} + i][y_{Cb} + y_{Bl} + k] \quad (8-343)$$

$$p_{i,k} = \text{recPicture}_L[x_{Cb} + x_{Bl} - i - 1][y_{Cb} + y_{Bl} + k] \quad (8-344)$$

Otherwise (edgeType is equal to EDGE_HOR), the sample values $p_{i,k}$ and $q_{i,k}$ with $i = 0..3$ and $k = 0$ and 3 are derived as follows:

$$q_{i,k} = \text{recPicture}_L[\text{xCb} + \text{xBl} + k][\text{yCb} + \text{yBl} + i] \quad (8-345)$$

$$p_{i,k} = \text{recPicture}_L[\text{xCb} + \text{xBl} + k][\text{yCb} + \text{yBl} - i - 1] \quad (8-346)$$

The variables Qp_Q and Qp_P are set equal to the Qp_Y values of the coding units which include the coding blocks containing the sample $q_{0,0}$ and $p_{0,0}$, respectively.

The variable qP_L is derived as follows:

$$qP_L = ((Qp_Q + Qp_P + 1) \gg 1) \quad (8-347)$$

The value of the variable β' is determined as specified in Table 8-12 based on the luma quantization parameter Q derived as follows:

$$Q = \text{Clip3}(0, 51, qP_L + (\text{slice_beta_offset_div2} \ll 1)) \quad (8-348)$$

where $\text{slice_beta_offset_div2}$ is the value of the syntax element $\text{slice_beta_offset_div2}$ for the slice that contains sample $q_{0,0}$.

The variable β is derived as follows:

$$\beta = \beta' * (1 \ll (\text{BitDepth}_Y - 8)) \quad (8-349)$$

The value of the variable t_C' is determined as specified in Table 8-12 based on the luma quantization parameter Q derived as follows:

$$Q = \text{Clip3}(0, 53, qP_L + 2 * (bS - 1) + (\text{slice_tc_offset_div2} \ll 1)) \quad (8-350)$$

where $\text{slice_tc_offset_div2}$ is the value of the syntax element $\text{slice_tc_offset_div2}$ for the slice that contains sample $q_{0,0}$.

The variable t_C is derived as follows:

$$t_C = t_C' * (1 \ll (\text{BitDepth}_Y - 8)) \quad (8-351)$$

Depending on the value of edgeType, the following applies:

– If edgeType is equal to EDGE_VER, the following ordered steps apply:

1. The variables $dpq0$, $dpq3$, dp , dq and d are derived as follows:

$$dp0 = \text{Abs}(p_{2,0} - 2 * p_{1,0} + p_{0,0}) \quad (8-352)$$

$$dp3 = \text{Abs}(p_{2,3} - 2 * p_{1,3} + p_{0,3}) \quad (8-353)$$

$$dq0 = \text{Abs}(q_{2,0} - 2 * q_{1,0} + q_{0,0}) \quad (8-354)$$

$$dq3 = \text{Abs}(q_{2,3} - 2 * q_{1,3} + q_{0,3}) \quad (8-355)$$

$$dpq0 = dp0 + dq0 \quad (8-356)$$

$$dpq3 = dp3 + dq3 \quad (8-357)$$

$$dp = dp0 + dp3 \quad (8-358)$$

$$dq = dq0 + dq3 \quad (8-359)$$

$$d = dpq0 + dpq3 \quad (8-360)$$

2. The variables dE , dEp and dEq are set equal to 0.

3. When d is less than β , the following ordered steps apply:

- a. The variable dpq is set equal to $2 * dpq0$.
 - b. For the sample location ($x_{Cb} + x_{Bl}$, $y_{Cb} + y_{Bl}$), the decision process for a luma sample as specified in clause 8.7.2.5.6 is invoked with sample values $p_{0,0}$, $p_{3,0}$, $q_{0,0}$, and $q_{3,0}$, the variables dpq , β and t_C as inputs, and the output is assigned to the decision $dSam0$.
 - c. The variable dpq is set equal to $2 * dpq3$.
 - d. For the sample location ($x_{Cb} + x_{Bl}$, $y_{Cb} + y_{Bl} + 3$), the decision process for a luma sample as specified in clause 8.7.2.5.6 is invoked with sample values $p_{0,3}$, $p_{3,3}$, $q_{0,3}$, and $q_{3,3}$, the variables dpq , β and t_C as inputs, and the output is assigned to the decision $dSam3$.
 - e. The variable dE is set equal to 1.
 - f. When $dSam0$ is equal to 1 and $dSam3$ is equal to 1, the variable dE is set equal to 2.
 - g. When dp is less than $(\beta + (\beta \gg 1)) \gg 3$, the variable dEp is set equal to 1.
 - h. When dq is less than $(\beta + (\beta \gg 1)) \gg 3$, the variable dEq is set equal to 1.
- Otherwise ($edgeType$ is equal to $EDGE_HOR$), the following ordered steps apply:
1. The variables $dpq0$, $dpq3$, dp , dq and d are derived as follows:

$$dp0 = Abs(p_{2,0} - 2 * p_{1,0} + p_{0,0}) \quad (8-361)$$

$$dp3 = Abs(p_{2,3} - 2 * p_{1,3} + p_{0,3}) \quad (8-362)$$

$$dq0 = Abs(q_{2,0} - 2 * q_{1,0} + q_{0,0}) \quad (8-363)$$

$$dq3 = Abs(q_{2,3} - 2 * q_{1,3} + q_{0,3}) \quad (8-364)$$

$$dpq0 = dp0 + dq0 \quad (8-365)$$

$$dpq3 = dp3 + dq3 \quad (8-366)$$

$$dp = dp0 + dp3 \quad (8-367)$$

$$dq = dq0 + dq3 \quad (8-368)$$

$$d = dpq0 + dpq3 \quad (8-369)$$
 2. The variables dE , dEp and dEq are set equal to 0.
 3. When d is less than β , the following ordered steps apply:
 - a. The variable dpq is set equal to $2 * dpq0$.
 - b. For the sample location ($x_{Cb} + x_{Bl}$, $y_{Cb} + y_{Bl}$), the decision process for a luma sample as specified in clause 8.7.2.5.6 is invoked with sample values $p_{0,0}$, $p_{3,0}$, $q_{0,0}$ and $q_{3,0}$, the variables dpq , β and t_C as inputs, and the output is assigned to the decision $dSam0$.
 - c. The variable dpq is set equal to $2 * dpq3$.
 - d. For the sample location ($x_{Cb} + x_{Bl} + 3$, $y_{Cb} + y_{Bl}$), the decision process for a luma sample as specified in clause 8.7.2.5.6 is invoked with sample values $p_{0,3}$, $p_{3,3}$, $q_{0,3}$ and $q_{3,3}$, the variables dpq , β and t_C as inputs, and the output is assigned to the decision $dSam3$.
 - e. The variable dE is set equal to 1.
 - f. When $dSam0$ is equal to 1 and $dSam3$ is equal to 1, the variable dE is set equal to 2.
 - g. When dp is less than $(\beta + (\beta \gg 1)) \gg 3$, the variable dEp is set equal to 1.
 - h. When dq is less than $(\beta + (\beta \gg 1)) \gg 3$, the variable dEq is set equal to 1.

Table 8-12 – Derivation of threshold variables β' and t_c' from input Q

Q	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
β'	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	6	7	8

8.7.2.5.4 Filtering process for luma block edges

Inputs to this process are:

- a luma picture sample array $recPicture_L$,
- a luma location (x_{Cb} , y_{Cb}) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a luma location (x_{Bl} , y_{Bl}) specifying the top-left sample of the current luma block relative to the top-left sample of the current luma coding block,
- a variable $edgeType$ specifying whether a vertical (EDGE_VER) or a horizontal (EDGE_HOR) edge is filtered,
- the variables dE , dEp and dEq containing decisions,
- the variables β and t_c .

Output of this process is the modified luma picture sample array $recPicture_L$.

Depending on the value of $edgeType$, the following applies:

- If $edgeType$ is equal to EDGE_VER, the following ordered steps apply:

1. The sample values $p_{i,k}$ and $q_{i,k}$ with $i = 0..3$ and $k = 0..3$ are derived as follows:

$$q_{i,k} = recPicture_L[x_{Cb} + x_{Bl} + i][y_{Cb} + y_{Bl} + k] \quad (8-370)$$

$$p_{i,k} = recPicture_L[x_{Cb} + x_{Bl} - i - 1][y_{Cb} + y_{Bl} + k] \quad (8-371)$$

2. When dE is not equal to 0, for each sample location ($x_{Cb} + x_{Bl}$, $y_{Cb} + y_{Bl} + k$), $k = 0..3$, the following ordered steps apply:

- a. The filtering process for a luma sample as specified in clause 8.7.2.5.7 is invoked with the sample values $p_{i,k}$, $q_{i,k}$ with $i = 0..3$, the locations (x_{Pi} , y_{Pi}) set equal to ($x_{Cb} + x_{Bl} - i - 1$, $y_{Cb} + y_{Bl} + k$) and (x_{Qi} , y_{Qi}) set equal to ($x_{Cb} + x_{Bl} + i$, $y_{Cb} + y_{Bl} + k$) with $i = 0..2$, the decision dE , the variables dEp and dEq and the variable t_c as inputs, and the number of filtered samples nDp and nDq from each side of the block boundary and the filtered sample values p_i' and q_j' as outputs.

- b. When nDp is greater than 0, the filtered sample values p_i' with $i = 0..nDp - 1$ replace the corresponding samples inside the sample array $recPicture_L$ as follows:

$$recPicture_L[x_{Cb} + x_{Bl} - i - 1][y_{Cb} + y_{Bl} + k] = p_i' \quad (8-372)$$

- c. When nDq is greater than 0, the filtered sample values q_j' with $j = 0..nDq - 1$ replace the corresponding samples inside the sample array $recPicture_L$ as follows:

$$recPicture_L[x_{Cb} + x_{Bl} + j][y_{Cb} + y_{Bl} + k] = q_j' \quad (8-373)$$

- Otherwise ($edgeType$ is equal to EDGE_HOR), the following ordered steps apply:

1. The sample values $p_{i,k}$ and $q_{i,k}$ with $i = 0..3$ and $k = 0..3$ are derived as follows:

$$q_{i,k} = \text{recPicture}_L[\text{xCb} + \text{xBl} + k][\text{yCb} + \text{yBl} + i] \quad (8-374)$$

$$p_{i,k} = \text{recPicture}_L[\text{xCb} + \text{xBl} + k][\text{yCb} + \text{yBl} - i - 1] \quad (8-375)$$

2. When dE is not equal to 0, for each sample location $(\text{xCb} + \text{xBl} + k, \text{yCb} + \text{yBl})$, $k = 0..3$, the following ordered steps apply:
 - a. The filtering process for a luma sample as specified in clause 8.7.2.5.7 is invoked with the sample values $p_{i,k}$, $q_{i,k}$ with $i = 0..3$, the locations $(\text{xP}_i, \text{yP}_i)$ set equal to $(\text{xCb} + \text{xBl} + k, \text{yCb} + \text{yBl} - i - 1)$ and $(\text{xQ}_i, \text{yQ}_i)$ set equal to $(\text{xCb} + \text{xBl} + k, \text{yCb} + \text{yBl} + i)$ with $i = 0..2$, the decision dE , the variables dEp and dEq , and the variable t_c as inputs, and the number of filtered samples nDp and nDq from each side of the block boundary and the filtered sample values p'_i and q'_j as outputs.
 - b. When nDp is greater than 0, the filtered sample values p'_i with $i = 0..nDp - 1$ replace the corresponding samples inside the sample array recPicture_L as follows:

$$\text{recPicture}_L[\text{xCb} + \text{xBl} + k][\text{yCb} + \text{yBl} - i - 1] = p'_i \quad (8-376)$$

- c. When nDq is greater than 0, the filtered sample values q'_j with $j = 0..nDq - 1$ replace the corresponding samples inside the sample array recPicture_L as follows:

$$\text{recPicture}_L[\text{xCb} + \text{xBl} + k][\text{yCb} + \text{yBl} + j] = q'_j \quad (8-377)$$

8.7.2.5.5 Filtering process for chroma block edges

This process is only invoked when ChromaArrayType is not equal to 0.

Inputs to this process are:

- a chroma picture sample array s' ,
- a chroma location (xCb, yCb) specifying the top-left sample of the current chroma coding block relative to the top-left chroma sample of the current picture,
- a chroma location (xBl, yBl) specifying the top-left sample of the current chroma block relative to the top-left sample of the current chroma coding block,
- a variable edgeType specifying whether a vertical (EDGE_VER) or a horizontal (EDGE_HOR) edge is filtered,
- a variable cQpPicOffset specifying the picture-level chroma quantization parameter offset.

Output of this process is the modified chroma picture sample array s' .

If edgeType is equal to EDGE_VER , the values p_i and q_i with $i = 0..1$ and $k = 0..3$ are derived as follows:

$$q_{i,k} = s'[\text{xCb} + \text{xBl} + i][\text{yCb} + \text{yBl} + k] \quad (8-378)$$

$$p_{i,k} = s'[\text{xCb} + \text{xBl} - i - 1][\text{yCb} + \text{yBl} + k] \quad (8-379)$$

Otherwise (edgeType is equal to EDGE_HOR), the sample values p_i and q_i with $i = 0..1$ and $k = 0..3$ are derived as follows:

$$q_{i,k} = s'[\text{xCb} + \text{xBl} + k][\text{yCb} + \text{yBl} + i] \quad (8-380)$$

$$p_{i,k} = s'[\text{xCb} + \text{xBl} + k][\text{yCb} + \text{yBl} - i - 1] \quad (8-381)$$

The variables Qp_Q and Qp_P are set equal to the Qp_Y values of the coding units which include the coding blocks containing the sample $q_{0,0}$ and $p_{0,0}$, respectively.

The index qPi is derived as follows:

$$qPi = ((Qp_Q + Qp_P + 1) \gg 1) + \text{cQpPicOffset} \quad (8-382)$$

The variable Qp_C is derived as follows:

- If ChromaArrayType is equal to 1, the variable Qp_C is determined based on qPi as specified in Table 8-10.
- Otherwise (ChromaArrayType is greater than 1), the variable Qp_C is set equal to $\text{Min}(qPi, 51)$.

NOTE – The variable `cQpPicOffset` provides an adjustment for the value of `pps_cb_qp_offset` or `pps_cr_qp_offset`, according to whether the filtered chroma component is the Cb or Cr component. However, to avoid the need to vary the amount of the adjustment within the picture, the filtering process does not include an adjustment for the value of `slice_cb_qp_offset` or `slice_cr_qp_offset`, nor (when `chroma_qp_offset_list_enabled_flag` is equal to 1) for the value of `CuQpOffsetCb` or `CuQpOffsetCr`.

The value of the variable t_c' is determined as specified in Table 8-12 based on the chroma quantization parameter Q derived as follows:

$$Q = \text{Clip3}(0, 53, Q_{pC} + 2 + (\text{slice_tc_offset_div2} \ll 1)) \quad (8-383)$$

where `slice_tc_offset_div2` is the value of the syntax element `slice_tc_offset_div2` for the slice that contains sample $q_{0,0}$.

The variable t_c is derived as follows:

$$t_c = t_c' * (1 \ll (\text{BitDepth}_C - 8)) \quad (8-384)$$

Depending on the value of `edgeType`, the following applies:

- If `edgeType` is equal to `EDGE_VER`, for each sample location $(x_{Cb} + x_{Bl}, y_{Cb} + y_{Bl} + k)$, $k = 0..3$, the following ordered steps apply:

1. The filtering process for a chroma sample as specified in clause 8.7.2.5.8 is invoked with the sample values $p_{i,k}$, $q_{i,k}$, with $i = 0..1$, the locations $(x_{Cb} + x_{Bl} - 1, y_{Cb} + y_{Bl} + k)$ and $(x_{Cb} + x_{Bl}, y_{Cb} + y_{Bl} + k)$ and the variable t_c as inputs, and the filtered sample values p_0' and q_0' as outputs.
2. The filtered sample values p_0' and q_0' replace the corresponding samples inside the sample array s' as follows:

$$s'[x_{Cb} + x_{Bl}][y_{Cb} + y_{Bl} + k] = q_0' \quad (8-385)$$

$$s'[x_{Cb} + x_{Bl} - 1][y_{Cb} + y_{Bl} + k] = p_0' \quad (8-386)$$

- Otherwise (`edgeType` is equal to `EDGE_HOR`), for each sample location $(x_{Cb} + x_{Bl} + k, y_{Cb} + y_{Bl})$, $k = 0..3$, the following ordered steps apply:

1. The filtering process for a chroma sample as specified in clause 8.7.2.5.8 is invoked with the sample values $p_{i,k}$, $q_{i,k}$, with $i = 0..1$, the locations $(x_{Cb} + x_{Bl} + k, y_{Cb} + y_{Bl} - 1)$ and $(x_{Cb} + x_{Bl} + k, y_{Cb} + y_{Bl})$, and the variable t_c as inputs, and the filtered sample values p_0' and q_0' as outputs.
2. The filtered sample values p_0' and q_0' replace the corresponding samples inside the sample array s' as follows:

$$s'[x_{Cb} + x_{Bl} + k][y_{Cb} + y_{Bl}] = q_0' \quad (8-387)$$

$$s'[x_{Cb} + x_{Bl} + k][y_{Cb} + y_{Bl} - 1] = p_0' \quad (8-388)$$

8.7.2.5.6 Decision process for a luma sample

Inputs to this process are:

- the sample values p_0 , p_3 , q_0 and q_3 ,
- the variables dpq , β and t_c .

Output of this process is the variable $dSam$ containing a decision.

The variable $dSam$ is specified as follows:

- If dpq is less than $(\beta \gg 2)$, $\text{Abs}(p_3 - p_0) + \text{Abs}(q_0 - q_3)$ is less than $(\beta \gg 3)$ and $\text{Abs}(p_0 - q_0)$ is less than $(5 * t_c + 1) \gg 1$, $dSam$ is set equal to 1.
- Otherwise, $dSam$ is set equal to 0.

8.7.2.5.7 Filtering process for a luma sample

Inputs to this process are:

- the luma sample values p_i and q_i with $i = 0..3$,
- the luma locations of p_i and q_i , (x_{Pi}, y_{Pi}) and (x_{Qi}, y_{Qi}) with $i = 0..2$,
- a variable dE ,

- the variables dEp and dEq containing decisions to filter samples p1 and q1, respectively,
- a variable tC.

Outputs of this process are:

- the number of filtered samples nDp and nDq,
- the filtered sample values p_i' and q_j' with i = 0..nDp – 1, j = 0..nDq – 1.

Depending on the value of dE, the following applies:

- If the variable dE is equal to 2, nDp and nDq are both set equal to 3 and the following strong filtering applies:

$$p_0' = \text{Clip3}(p_0 - 2 * t_C, p_0 + 2 * t_C, (p_2 + 2 * p_1 + 2 * p_0 + 2 * q_0 + q_1 + 4) \gg 3) \quad (8-389)$$

$$p_1' = \text{Clip3}(p_1 - 2 * t_C, p_1 + 2 * t_C, (p_2 + p_1 + p_0 + q_0 + 2) \gg 2) \quad (8-390)$$

$$p_2' = \text{Clip3}(p_2 - 2 * t_C, p_2 + 2 * t_C, (2 * p_3 + 3 * p_2 + p_1 + p_0 + q_0 + 4) \gg 3) \quad (8-391)$$

$$q_0' = \text{Clip3}(q_0 - 2 * t_C, q_0 + 2 * t_C, (p_1 + 2 * p_0 + 2 * q_0 + 2 * q_1 + q_2 + 4) \gg 3) \quad (8-392)$$

$$q_1' = \text{Clip3}(q_1 - 2 * t_C, q_1 + 2 * t_C, (p_0 + q_0 + q_1 + q_2 + 2) \gg 2) \quad (8-393)$$

$$q_2' = \text{Clip3}(q_2 - 2 * t_C, q_2 + 2 * t_C, (p_0 + q_0 + q_1 + 3 * q_2 + 2 * q_3 + 4) \gg 3) \quad (8-394)$$

- Otherwise, nDp and nDq are set both equal to 0 and the following weak filtering applies:

- The following applies:

$$\Delta = (9 * (q_0 - p_0) - 3 * (q_1 - p_1) + 8) \gg 4 \quad (8-395)$$

- When Abs(Δ) is less than tC * 10, the following ordered steps apply:

1. The filtered sample values p₀' and q₀' are specified as follows:

$$\Delta = \text{Clip3}(-t_C, t_C, \Delta) \quad (8-396)$$

$$p_0' = \text{Clip1}_Y(p_0 + \Delta) \quad (8-397)$$

$$q_0' = \text{Clip1}_Y(q_0 - \Delta) \quad (8-398)$$

2. When dEp is equal to 1, the filtered sample value p₁' is specified as follows:

$$\Delta p = \text{Clip3}(-(t_C \gg 1), t_C \gg 1, (((p_2 + p_0 + 1) \gg 1) - p_1 + \Delta) \gg 1) \quad (8-399)$$

$$p_1' = \text{Clip1}_Y(p_1 + \Delta p) \quad (8-400)$$

3. When dEq is equal to 1, the filtered sample value q₁' is specified as follows:

$$\Delta q = \text{Clip3}(-(t_C \gg 1), t_C \gg 1, (((q_2 + q_0 + 1) \gg 1) - q_1 - \Delta) \gg 1) \quad (8-401)$$

$$q_1' = \text{Clip1}_Y(q_1 + \Delta q) \quad (8-402)$$

4. nDp is set equal to dEp + 1 and nDq is set equal to dEq + 1.

When nDp is greater than 0 and one or more of the following conditions are true, nDp is set equal to 0:

- pcm_loop_filter_disabled_flag is equal to 1 and pcm_flag[xP₀][yP₀] is equal to 1.
- cu_transquant_bypass_flag of the coding unit that includes the coding block containing the sample p₀ is equal to 1.
- palette_mode_flag of the coding unit that includes the coding block containing the sample p₀ is equal to 1.

When nDq is greater than 0 and one or more of the following conditions are true, nDq is set equal to 0:

- pcm_loop_filter_disabled_flag is equal to 1 and pcm_flag[xQ₀][yQ₀] is equal to 1.
- cu_transquant_bypass_flag of the coding unit that includes the coding block containing the sample q₀ is equal to 1.
- palette_mode_flag of the coding unit that includes the coding block containing the sample q₀ is equal to 1.

8.7.2.5.8 Filtering process for a chroma sample

This process is only invoked when ChromaArrayType is not equal to 0.

Inputs to this process are:

- the chroma sample values p_i and q_i with i = 0..1,
- the chroma locations of p₀ and q₀, (xP₀, yP₀) and (xQ₀, yQ₀),
- a variable t_C.

Outputs of this process are the filtered sample values p₀' and q₀'.

The filtered sample values p₀' and q₀' are derived as follows:

$$\Delta = \text{Clip3}(-t_C, t_C, ((((q_0 - p_0) \ll 2) + p_1 - q_1 + 4) \gg 3)) \quad (8-403)$$

$$p_0' = \text{Clip1}_C(p_0 + \Delta) \quad (8-404)$$

$$q_0' = \text{Clip1}_C(q_0 - \Delta) \quad (8-405)$$

When one or more of the following conditions are true, the filtered sample value, p₀' is substituted by the corresponding input sample value p₀:

- pcm_loop_filter_disabled_flag is equal to 1 and pcm_flag[xP₀ * SubWidthC][yP₀ * SubHeightC] is equal to 1.
- cu_transquant_bypass_flag of the coding unit that includes the coding block containing the sample p₀ is equal to 1.
- palette_mode_flag of the coding unit that includes the coding block containing the sample p₀ is equal to 1.

When one or more of the following conditions are true, the filtered sample value, q₀' is substituted by the corresponding input sample value q₀:

- pcm_loop_filter_disabled_flag is equal to 1 and pcm_flag[xQ₀ * SubWidthC][yQ₀ * SubHeightC] is equal to 1.
- cu_transquant_bypass_flag of the coding unit that includes the coding block containing the sample q₀ is equal to 1.
- palette_mode_flag of the coding unit that includes the coding block containing the sample q₀ is equal to 1.

8.7.3 Sample adaptive offset process

8.7.3.1 General

Inputs to this process are the reconstructed picture sample array prior to sample adaptive offset recPicture_L and, when ChromaArrayType is not equal to 0, the arrays recPicture_{Cb} and recPicture_{Cr}.

Outputs of this process are the modified reconstructed picture sample array after sample adaptive offset saoPicture_L and, when ChromaArrayType is not equal to 0, the arrays saoPicture_{Cb} and saoPicture_{Cr}.

This process is performed on a CTB basis after the completion of the deblocking filter process for the decoded picture.

The sample values in the modified reconstructed picture sample array saoPicture_L and, when ChromaArrayType is not equal to 0, the arrays saoPicture_{Cb} and saoPicture_{Cr} are initially set equal to the sample values in the reconstructed picture sample array recPicture_L and, when ChromaArrayType is not equal to 0, the arrays recPicture_{Cb} and recPicture_{Cr}, respectively.

For every CTU with CTB location (rx, ry), where rx = 0..PicWidthInCtbsY – 1 and ry = 0..PicHeightInCtbsY – 1, the following applies:

- When slice_sao_luma_flag of the current slice is equal to 1, the CTB modification process as specified in clause 8.7.3.2 is invoked with recPicture set equal to recPicture_L, cIdx set equal to 0, (rx, ry), and both nCtbSw and nCtbSh set equal to CtbSizeY as inputs, and the modified luma picture sample array saoPicture_L as output.
- When ChromaArrayType is not equal to 0 and slice_sao_chroma_flag of the current slice is equal to 1, the CTB modification process as specified in clause 8.7.3.2 is invoked with recPicture set equal to recPicture_{Cb}, cIdx set equal

to 1, (rx, ry), nCtbSw set equal to $(1 \ll \text{CtbLog2SizeY}) / \text{SubWidthC}$ and nCtbSh set equal to $(1 \ll \text{CtbLog2SizeY}) / \text{SubHeightC}$ as inputs, and the modified chroma picture sample array saoPicture_{Cb} as output.

- When ChromaArrayType is not equal to 0 and slice_sao_chroma_flag of the current slice is equal to 1, the CTB modification process as specified in clause 8.7.3.2 is invoked with recPicture set equal to recPicture_{Cr}, cIdx set equal to 2, (rx, ry), nCtbSw set equal to $(1 \ll \text{CtbLog2SizeY}) / \text{SubWidthC}$ and nCtbSh set equal to $(1 \ll \text{CtbLog2SizeY}) / \text{SubHeightC}$ as inputs, and the modified chroma picture sample array saoPicture_{Cr} as output.

8.7.3.2 CTB modification process

Inputs to this process are:

- the picture sample array recPicture for the colour component cIdx,
- a variable cIdx specifying the colour component index,
- a pair of variables (rx, ry) specifying the CTB location,
- the CTB width nCtbSw and height nCtbSh.

Output of this process is a modified picture sample array saoPicture for the colour component cIdx.

The variable bitDepth is derived as follows:

- If cIdx is equal to 0, bitDepth is set equal to BitDepth_Y.
- Otherwise, bitDepth is set equal to BitDepth_C.

The location (xCtb, yCtb), specifying the top-left sample of the current CTB for the colour component cIdx relative to the top-left sample of the current picture component cIdx, is derived as follows:

$$(xCtb, yCtb) = (rx * nCtbSw, ry * nCtbSh) \quad (8-406)$$

The sample locations inside the current CTB are derived as follows:

$$(xS_i, yS_j) = (xCtb + i, yCtb + j) \quad (8-407)$$

$$(xY_i, yY_j) = (cIdx == 0) ? (xS_i, yS_j) : (xS_i * \text{SubWidthC}, yS_j * \text{SubHeightC}) \quad (8-408)$$

For all sample locations (xS_i, yS_j) and (xY_i, yY_j) with $i = 0..nCtbSw - 1$ and $j = 0..nCtbSh - 1$, depending on the values of pcm_loop_filter_disabled_flag, pcm_flag[xY_i][yY_j] and cu_transquant_bypass_flag of the coding unit which includes the coding block covering recPicture[xS_i][yS_j], the following applies:

- If one or more of the following conditions are true, saoPicture[xS_i][yS_j] is not modified:
 - pcm_loop_filter_disabled_flag and pcm_flag[xY_i][yY_j] are both equal to 1.
 - cu_transquant_bypass_flag is equal to 1.
 - SaoTypeIdx[cIdx][rx][ry] is equal to 0.
- Otherwise, if SaoTypeIdx[cIdx][rx][ry] is equal to 2, the following ordered steps apply:
 1. The values of hPos[k] and vPos[k] for $k = 0..1$ are specified in Table 8-13 based on SaoEoClass[cIdx][rx][ry].
 2. The variable edgeIdx is derived as follows:
 - The modified sample locations (xS_{ik}', yS_{jk}') and (xY_{ik}', yY_{jk}') are derived as follows:

$$(xS_{ik}', yS_{jk}') = (xS_i + hPos[k], yS_j + vPos[k]) \quad (8-409)$$

$$(xY_{ik}', yY_{jk}') = (cIdx == 0) ? (xS_{ik}', yS_{jk}') : (xS_{ik}' * \text{SubWidthC}, yS_{jk}' * \text{SubHeightC}) \quad (8-410)$$

- If one or more of the following conditions for all sample locations (xS_{ik}', yS_{jk}') and (xY_{ik}', yY_{jk}') with $k = 0..1$ are true, edgeIdx is set equal to 0:
 - The sample at location (xS_{ik}', yS_{jk}') is outside the picture boundaries.
 - The sample at location (xS_{ik}', yS_{jk}') belongs to a different slice and one of the following two conditions is true:

- $\text{MinTbAddrZs}[xY_{ik}' \gg \text{MinTbLog2SizeY}][yY_{jk}' \gg \text{MinTbLog2SizeY}]$ is less than $\text{MinTbAddrZs}[xY_i \gg \text{MinTbLog2SizeY}][yY_j \gg \text{MinTbLog2SizeY}]$ and $\text{slice_loop_filter_across_slices_enabled_flag}$ in the slice which the sample $\text{recPicture}[xS_i][yS_j]$ belongs to is equal to 0.
- $\text{MinTbAddrZs}[xY_i \gg \text{MinTbLog2SizeY}][yY_j \gg \text{MinTbLog2SizeY}]$ is less than $\text{MinTbAddrZs}[xY_{ik}' \gg \text{MinTbLog2SizeY}][yY_{jk}' \gg \text{MinTbLog2SizeY}]$ and $\text{slice_loop_filter_across_slices_enabled_flag}$ in the slice which the sample $\text{recPicture}[xS_{ik}'][yS_{jk}']$ belongs to is equal to 0.
- $\text{loop_filter_across_tiles_enabled_flag}$ is equal to 0 and the sample at location (xS_{ik}', yS_{jk}') belongs to a different tile.
- Otherwise, edgeIdx is derived as follows:
- The following applies:

$$\begin{aligned} \text{edgeIdx} = & \\ & 2 + \text{Sign}(\text{recPicture}[xS_i][yS_j] - \text{recPicture}[xS_i + \text{hPos}[0]][yS_j + \text{vPos}[0]]) + \\ & \text{Sign}(\text{recPicture}[xS_i][yS_j] - \text{recPicture}[xS_i + \text{hPos}[1]][yS_j + \text{vPos}[1]]) \end{aligned} \quad (8-411)$$

- When edgeIdx is equal to 0, 1, or 2, edgeIdx is modified as follows:

$$\text{edgeIdx} = (\text{edgeIdx} == 2) ? 0 : (\text{edgeIdx} + 1) \quad (8-412)$$

3. The modified picture sample array $\text{saoPicture}[xS_i][yS_j]$ is derived as follows:

$$\begin{aligned} \text{saoPicture}[xS_i][yS_j] = & \text{Clip3}(0, (1 \ll \text{bitDepth}) - 1, \text{recPicture}[xS_i][yS_j] + \\ & \text{SaoOffsetVal}[\text{cIdx}][\text{rx}][\text{ry}][\text{edgeIdx}]) \end{aligned} \quad (8-413)$$

- Otherwise ($\text{SaoTypeIdx}[\text{cIdx}][\text{rx}][\text{ry}]$ is equal to 1), the following ordered steps apply:

 1. The variable bandShift is set equal to $\text{bitDepth} - 5$.
 2. The variable saoLeftClass is set equal to $\text{sao_band_position}[\text{cIdx}][\text{rx}][\text{ry}]$.
 3. The list bandTable is defined with 32 elements and all elements are initially set equal to 0. Then, four of its elements (indicating the starting position of bands for explicit offsets) are modified as follows:

$$\begin{aligned} \text{for}(\text{k} = 0; \text{k} < 4; \text{k}++) \\ \text{bandTable}[(\text{k} + \text{saoLeftClass}) \& 31] = \text{k} + 1 \end{aligned} \quad (8-414)$$

4. The variable bandIdx is set equal to $\text{bandTable}[\text{recPicture}[xS_i][yS_j] \gg \text{bandShift}]$.
5. The modified picture sample array $\text{saoPicture}[xS_i][yS_j]$ is derived as follows:

$$\begin{aligned} \text{saoPicture}[xS_i][yS_j] = & \text{Clip3}(0, (1 \ll \text{bitDepth}) - 1, \text{recPicture}[xS_i][yS_j] + \\ & \text{SaoOffsetVal}[\text{cIdx}][\text{rx}][\text{ry}][\text{bandIdx}]) \end{aligned} \quad (8-415)$$

Table 8-13 – Specification of hPos and vPos according to the sample adaptive offset class

$\text{SaoEoClass}[\text{cIdx}][\text{rx}][\text{ry}]$	0	1	2	3
$\text{hPos}[0]$	−1	0	−1	1
$\text{hPos}[1]$	1	0	1	−1
$\text{vPos}[0]$	0	−1	−1	−1
$\text{vPos}[1]$	0	1	1	1

9 Parsing process

9.1 General

Inputs to this process are bits from the RBSP.

Outputs of this process are syntax element values.

This process is invoked when the descriptor of a syntax element in the syntax tables is equal to ue(v), se(v) (see clause 9.2), or ae(v) (see clause 9.3).

9.2 Parsing process for 0-th order Exp-Golomb codes

9.2.1 General

This process is invoked when the descriptor of a syntax element in the syntax tables is equal to ue(v) or se(v).

Inputs to this process are bits from the RBSP.

Outputs of this process are syntax element values.

Syntax elements coded as ue(v) or se(v) are Exp-Golomb-coded. The parsing process for these syntax elements begins with reading the bits starting at the current location in the bitstream up to and including the first non-zero bit, and counting the number of leading bits that are equal to 0. This process is specified as follows:

```

leadingZeroBits = -1
for( b = 0; !b; leadingZeroBits++ )
    b = read_bits( 1 )

```

(9-1)

The variable codeNum is then assigned as follows:

$$\text{codeNum} = 2^{\text{leadingZeroBits}} - 1 + \text{read_bits}(\text{leadingZeroBits}) \quad (9-2)$$

where the value returned from read_bits(leadingZeroBits) is interpreted as a binary representation of an unsigned integer with most significant bit written first.

Table 9-1 illustrates the structure of the Exp-Golomb code by separating the bit string into "prefix" and "suffix" bits. The "prefix" bits are those bits that are parsed as specified above for the computation of leadingZeroBits, and are shown as either 0 or 1 in the bit string column of Table 9-1. The "suffix" bits are those bits that are parsed in the computation of codeNum and are shown as x_i in Table 9-1, with i in the range of 0 to leadingZeroBits - 1, inclusive. Each x_i is equal to either 0 or 1.

Table 9-1 – Bit strings with "prefix" and "suffix" bits and assignment to codeNum ranges (informative)

Bit string form	Range of codeNum
1	0
0 1 x_0	1..2
0 0 1 $x_1 x_0$	3..6
0 0 0 1 $x_2 x_1 x_0$	7..14
0 0 0 0 1 $x_3 x_2 x_1 x_0$	15..30
0 0 0 0 0 1 $x_4 x_3 x_2 x_1 x_0$	31..62
...	...

Table 9-2 illustrates explicitly the assignment of bit strings to codeNum values.

Table 9-2 – Exp-Golomb bit strings and codeNum in explicit form and used as ue(v) (informative)

Bit string	codeNum
1	0
0 1 0	1
0 1 1	2
0 0 1 0 0	3
0 0 1 0 1	4
0 0 1 1 0	5
0 0 1 1 1	6
0 0 0 1 0 0 0	7
0 0 0 1 0 0 1	8
0 0 0 1 0 1 0	9
...	...

Depending on the descriptor, the value of a syntax element is derived as follows:

- If the syntax element is coded as ue(v), the value of the syntax element is equal to codeNum.
- Otherwise (the syntax element is coded as se(v)), the value of the syntax element is derived by invoking the mapping process for signed Exp-Golomb codes as specified in clause 9.2.2 with codeNum as input.

9.2.2 Mapping process for signed Exp-Golomb codes

Input to this process is codeNum as specified in clause 9.2.

Output of this process is a value of a syntax element coded as se(v).

The syntax element is assigned to the codeNum by ordering the syntax element by its absolute value in increasing order and representing the positive value for a given absolute value with the lower codeNum. Table 9-3 provides the assignment rule.

Table 9-3 – Assignment of syntax element to codeNum for signed Exp-Golomb coded syntax elements se(v)

codeNum	syntax element value
0	0
1	1
2	–1
3	2
4	–2
5	3
6	–3
k	$(-1)^{k+1} \text{Ceil}(k \div 2)$

9.3 CABAC parsing process for slice segment data

9.3.1 General

This process is invoked when parsing syntax elements with descriptor `ae(v)` in clauses 7.3.8.1 through 7.3.8.12.

Inputs to this process are a request for a value of a syntax element and values of prior parsed syntax elements.

Output of this process is the value of the syntax element.

The initialization process as specified in clause 9.3.2 is invoked when starting the parsing of one or more of the following:

1. The slice segment data syntax specified in clause 7.3.8.1,
2. The CTU syntax specified in clause 7.3.8.2 and the CTU is the first CTU in a tile,
3. The CTU syntax specified in clause 7.3.8.2, `entropy_coding_sync_enabled_flag` is equal to 1 and the associated luma CTB is the first luma CTB in a CTU row of a tile.

The parsing of syntax elements proceeds as follows:

When `cabac_bypass_alignment_enabled_flag` is equal to 1, the request for a value of a syntax element is for either the syntax elements `coeff_abs_level_remaining[]` or `coeff_sign_flag[]` and `escapeDataPresent` is equal to 1, the alignment process prior to aligned bypass decoding as specified in clause 9.3.4.3.6 is invoked.

For each requested value of a syntax element a binarization is derived as specified in clause 9.3.3.

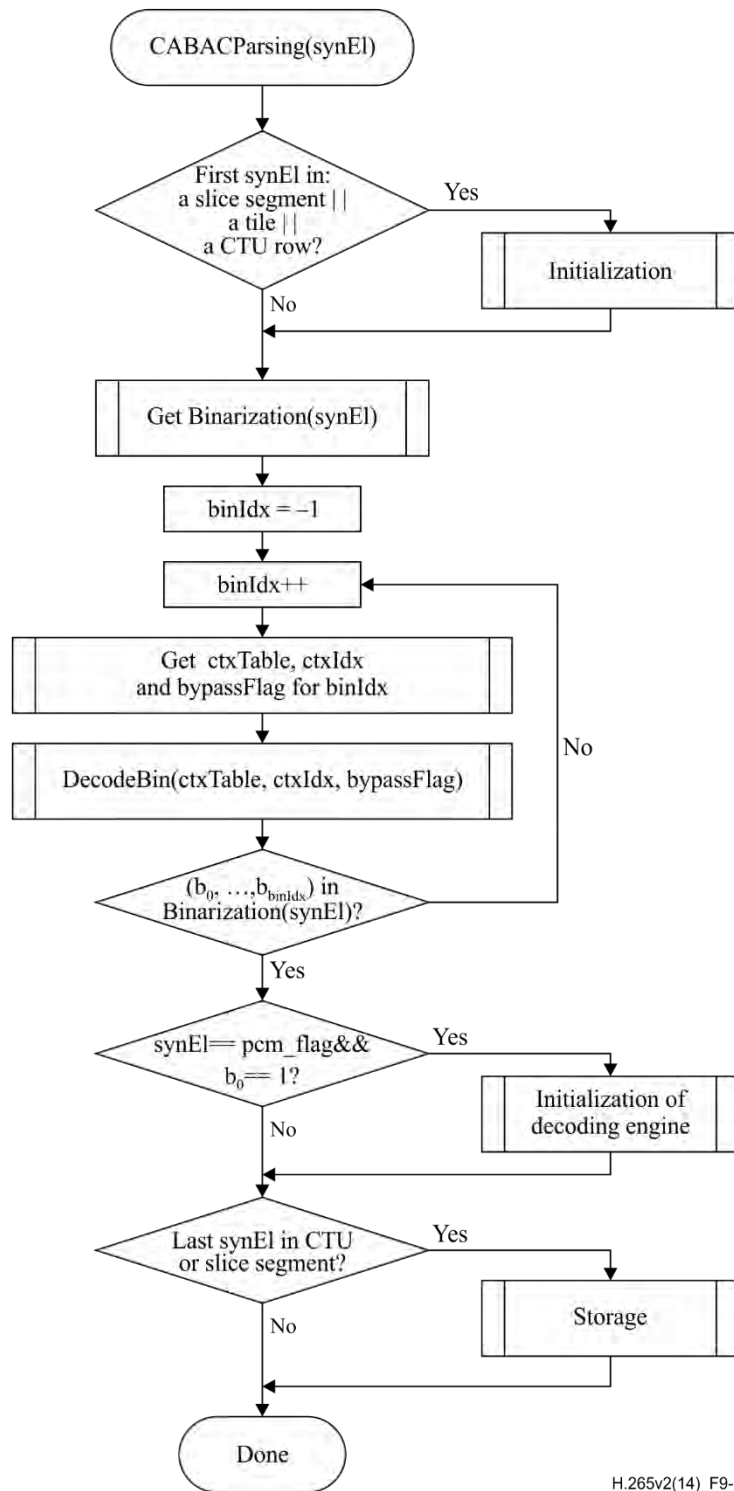

The binarization for the syntax element and the sequence of parsed bins determines the decoding process flow as described in clause 9.3.4.

In case the request for a value of a syntax element is processed for the syntax element `pcm_flag` and the decoded value of `pcm_flag` is equal to 1, the decoding engine is initialized after the decoding of any `pcm_alignment_zero_bit` and all `pcm_sample_luma` and `pcm_sample_chroma` data as specified in clause 9.3.2.6.

The storage process for context variables is applied as follows:

- When ending the parsing of the CTU syntax in clause 7.3.8.2, `entropy_coding_sync_enabled_flag` is equal to 1 and either `CtbAddrInRs % PicWidthInCtbsY` is equal to 1 or both `CtbAddrInRs` is greater than 1 and `TileId[CtbAddrInTs]` is not equal to `TileId[CtbAddrRsToTs[CtbAddrInRs – 2]]`, the storage process for context variables, Rice parameter initialization states, and palette predictor variables as specified in clause 9.3.2.4 is invoked with `TableStateIdxWpp`, `TableMpsValWpp`, `TableStatCoeffWpp` when `persistent_rice_adaptation_enabled_flag` is equal to 1, and `PredictorPaletteSizeWpp` and `PredictorPaletteEntriesWpp` when `palette_mode_enabled_flag` is equal to 1 as outputs.
- When ending the parsing of the general slice segment data syntax in clause 7.3.8.1, `dependent_slice_segments_enabled_flag` is equal to 1 and `end_of_slice_segment_flag` is equal to 1, the storage process for context variables, Rice parameter initialization states, and palette predictor variables as specified in clause 9.3.2.4 is invoked with `TableStateIdxDs`, `TableMpsValDs`, `TableStatCoeffDs` when `persistent_rice_adaptation_enabled_flag` is equal to 1, and `PredictorPaletteSizeDs` and `PredictorPaletteEntriesDs` when `palette_mode_enabled_flag` is equal to 1 as outputs.

The whole CABAC parsing process for a syntax element `synEl` is illustrated in Figure 9-1.

H.265v2(14)_F9-1

Figure 9-1 – Illustration of CABAC parsing process for a syntax element synEl (informative)

9.3.2 Initialization process

9.3.2.1 General

Outputs of this process are initialized CABAC internal variables, the initialized Rice parameter initialization states StatCoeff, and the initialized palette predictor variables.

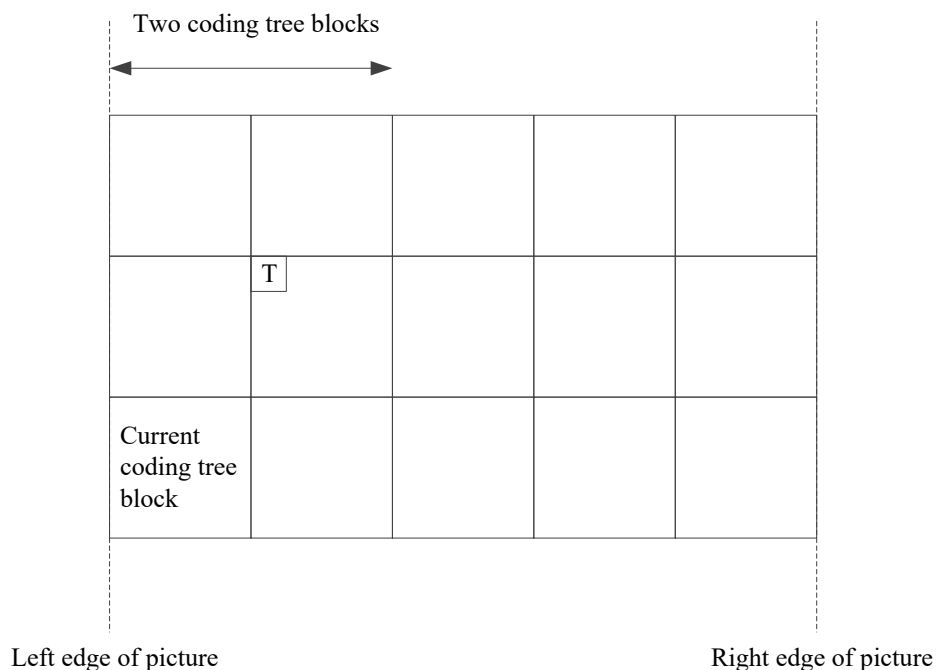

Figure 9-2 – Spatial neighbour T that is used to invoke the CTB availability derivation process relative to the current CTB (informative)

The context variables of the arithmetic decoding engine, Rice parameter initialization states, and palette predictor variables are initialized as follows:

- If the CTU is the first CTU in a tile, the following applies:
 - The initialization process for context variables is invoked as specified in clause 9.3.2.2.
 - The variables StatCoeff[k] are set equal to 0, for k in the range 0 to 3, inclusive.
 - The initialization process for palette predictor variables is invoked as specified in clause 9.3.2.3.
- Otherwise, if entropy_coding_sync_enabled_flag is equal to 1 and either CtbAddrInRs % PicWidthInCtbsY is equal to 0 or TileId[CtbAddrInTs] is not equal to TileId[CtbAddrRsToTs[CtbAddrInRs – 1]], the following applies:
 - The location (xNbT, yNbT) of the top-left luma sample of the spatial neighbouring block T (Figure 9-2) is derived using the location (x0, y0) of the top-left luma sample of the current CTB as follows:

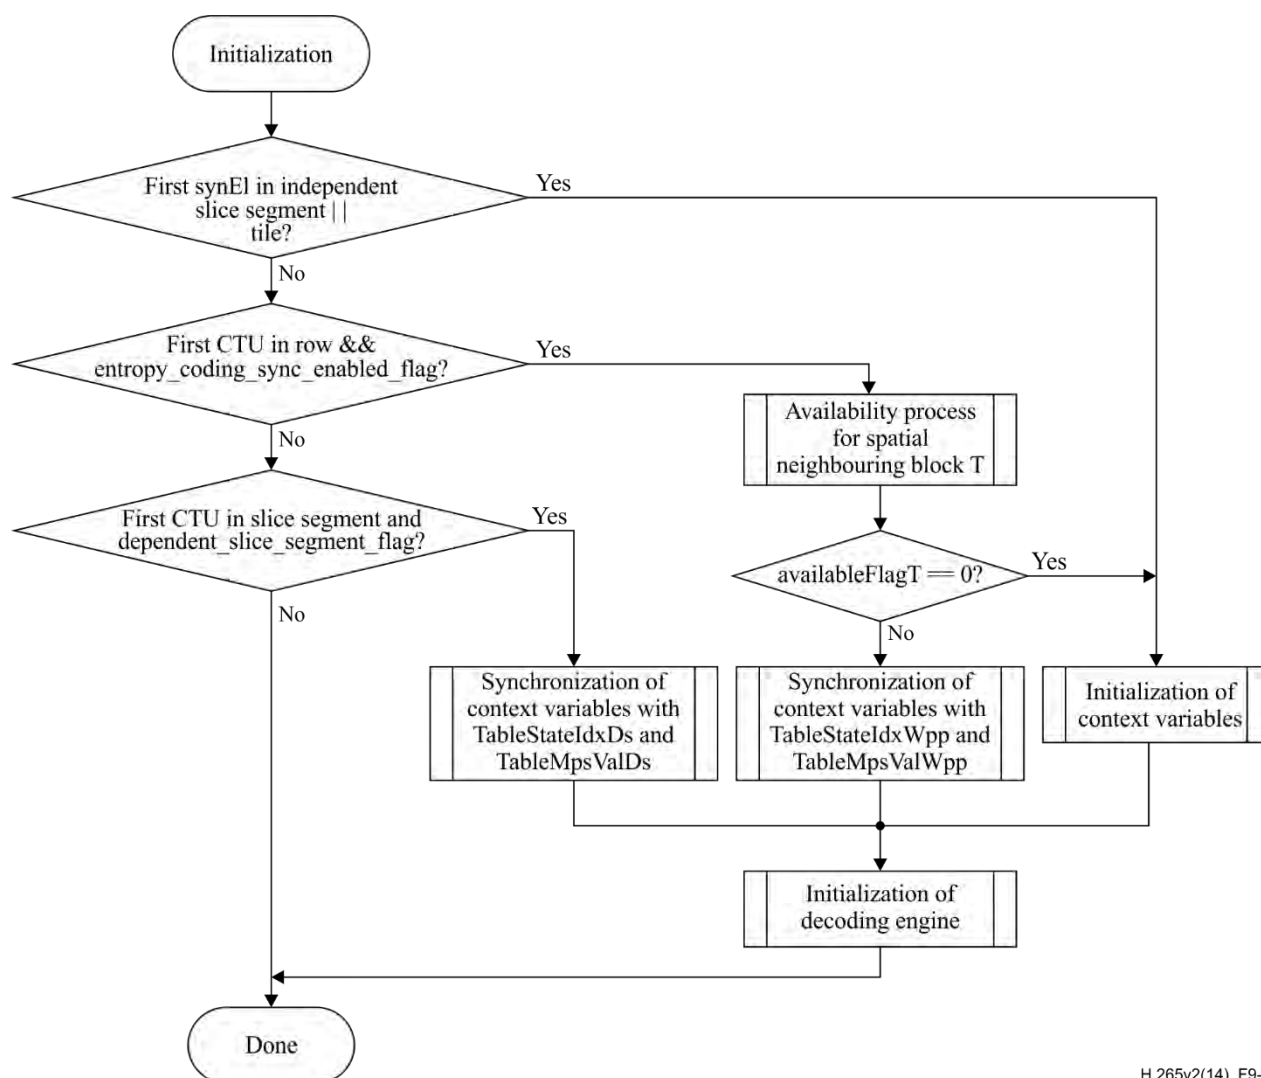

$$(xNbT, yNbT) = (x0 + CtbSizeY, y0 - CtbSizeY) \quad (9-3)$$

- The availability derivation process for a block in z-scan order as specified in clause 6.4.1 is invoked with the location (xCurr, yCurr) set equal to (x0, y0) and the neighbouring location (xNbY, yNbY) set equal to (xNbT, yNbT) as inputs, and the output is assigned to availableFlagT.
- The synchronization process for context variables, Rice parameter initialization states, and palette predictor variables is invoked as follows:
 - If availableFlagT is equal to 1, the synchronization process for context variables, Rice parameter initialization states, and palette predictor variables as specified in clause 9.3.2.5 is invoked with TableStateIdxWpp, TableMpsValWpp, TableStatCoeffWpp, PredictorPaletteSizeWpp, and TablePredictorPaletteEntriesWpp as inputs.
 - Otherwise, the following applies:
 - The initialization process for context variables is invoked as specified in clause 9.3.2.2.

- The variables StatCoeff[k] are set equal to 0, for k in the range 0 to 3, inclusive.
- The initialization process for palette predictor variables is invoked as specified in clause 9.3.2.3.
- Otherwise, if CtbAddrInRs is equal to slice_segment_address and dependent_slice_segment_flag is equal to 1, the synchronization process for context variables and Rice parameter initialization states as specified in clause 9.3.2.5 is invoked with TableStateIdxDs, TableMpsValDs, TableStatCoeffDs, PredictorPaletteSizeDs, and TablePredictorPaletteEntriesDs as inputs.
- Otherwise, the following applies:
 - The initialization process for context variables is invoked as specified in clause 9.3.2.2.
 - The variables StatCoeff[k] are set equal to 0, for k in the range 0 to 3, inclusive.
 - The initialization process for palette predictor variables is invoked as specified in clause 9.3.2.3.

The initialization process for the arithmetic decoding engine is invoked as specified in clause 9.3.2.6.

The whole initialization process for a syntax element synEl is illustrated in the flowchart of Figure 9-3.

H.265v2(14)_F9-3

Figure 9-3 – Illustration of CABAC initialization process (informative)

9.3.2.2 Initialization process for context variables

Outputs of this process are the initialized CABAC context variables indexed by ctxTable and ctxIdx.

Table 9-5 to Table 9-37 contain the values of the 8 bit variable initValue used in the initialization of context variables that are assigned to all syntax elements in clauses 7.3.8.1 through 7.3.8.12, except end_of_slice_segment_flag, end_of_subset_one_bit and pcm_flag.

For each context variable, the two variables pStateIdx and valMps are initialized.

NOTE 1 – The variable pStateIdx corresponds to a probability state index and the variable valMps corresponds to the value of the most probable symbol as further described in clause 9.3.4.3.

From the 8 bit table entry initValue, the two 4 bit variables slopeIdx and offsetIdx are derived as follows:

$$\begin{aligned} \text{slopeIdx} &= \text{initValue} \gg 4 \\ \text{offsetIdx} &= \text{initValue} \& 15 \end{aligned} \quad (9-4)$$

The variables m and n, used in the initialization of context variables, are derived from slopeIdx and offsetIdx as follows:

$$\begin{aligned} m &= \text{slopeIdx} * 5 - 45 \\ n &= (\text{offsetIdx} \ll 3) - 16 \end{aligned} \quad (9-5)$$

The two values assigned to pStateIdx and valMps for the initialization are derived from SliceQp_V, which is derived in Equation 7-54. Given the variables m and n, the initialization is specified as follows:

$$\begin{aligned} \text{preCtxState} &= \text{Clip3}(1, 126, ((m * \text{Clip3}(0, 51, \text{SliceQp}_V)) \gg 4) + n) \\ \text{valMps} &= (\text{preCtxState} \leq 63) ? 0 : 1 \\ \text{pStateIdx} &= \text{valMps} ? (\text{preCtxState} - 64) : (63 - \text{preCtxState}) \end{aligned} \quad (9-6)$$

In Table 9-4, the ctxIdx for which initialization is needed for each of the three initialization types, specified by the variable initType, are listed. Also listed is the table number that includes the values of initValue needed for the initialization. For P and B slice types, the derivation of initType depends on the value of the cabac_init_flag syntax element. The variable initType is derived as follows:

$$\begin{aligned} &\text{if}(\text{slice_type} == \text{I}) \\ &\quad \text{initType} = 0 \\ &\text{else if}(\text{slice_type} == \text{P}) \\ &\quad \text{initType} = \text{cabac_init_flag} ? 2 : 1 \\ &\text{else} \\ &\quad \text{initType} = \text{cabac_init_flag} ? 1 : 2 \end{aligned} \quad (9-7)$$

Table 9-4 – Association of ctxIdx and syntax elements for each initializationType in the initialization process

Syntax structure	Syntax element	ctxTable	initType		
			0	1	2

NOTE 2 – ctxTable equal to 0 and ctxIdx equal to 0 are associated with end_of_slice_segment_flag, end_of_subset_one_bit and pcm_flag. The decoding process specified in clause 9.3.4.3.5 applies to ctxTable equal to 0 and ctxIdx equal to 0. This decoding process, however, may also be implemented by using the decoding process specified in clause 9.3.4.3.2. In this case, the initial values associated with ctxTable equal to 0 and ctxIdx equal to 0 are specified to be pStateIdx = 63 and valMps = 0, where pStateIdx = 63 represents a non-adapting probability state.

9.3.2.3 Initialization process for palette predictor entries

Outputs of this process are the initialized palette predictor variables PredictorPaletteSize and PredictorPaletteEntries.

The variable numComps is derived as follows:

$$\text{numComps} = (\text{ChromaArrayType} == 0) ? 1 : 3 \quad (9-8)$$

- If pps_palette_predictor_initializers_present_flag is equal to 1, the following applies:

- PredictorPaletteSize is set equal to pps_num_palette_predictor_initializers.
- The array PredictorPaletteEntries is derived as follows:

$$\begin{aligned} &\text{for(comp = 0; comp < numComps; comp++)} \\ &\quad \text{for(i = 0; i < PredictorPaletteSize; i++)} \\ &\quad \quad \text{PredictorPaletteEntries[comp][i] = pps_palette_predictor_initializer[comp][i]} \end{aligned} \quad (9-9)$$

- Otherwise (pps_palette_predictor_initializers_present_flag is equal to 0), if sps_palette_predictor_initializers_present_flag is equal to 1, the following applies:
- PredictorPaletteSize is set equal to sps_num_palette_predictor_initializers_minus1 plus 1.
- The array PredictorPaletteEntries is derived as follows:

$$\begin{aligned} &\text{for(comp = 0; comp < numComps; comp++)} \\ &\quad \text{for(i = 0; i < PredictorPaletteSize; i++)} \\ &\quad \quad \text{PredictorPaletteEntries[comp][i] = sps_palette_predictor_initializer[comp][i]} \end{aligned} \quad (9-10)$$

Otherwise (pps_palette_predictor_initializers_present_flag is equal to 0 and sps_palette_predictor_initializers_present_flag is equal to 0), PredictorPaletteSize is set equal to 0.

9.3.2.4 Storage process for context variables, Rice parameter initialization states, and palette predictor variables

Inputs to this process are:

- The CABAC context variables indexed by ctxTable and ctxIdx.
- The Rice parameter initialization states indexed by k.
- The palette predictor variables, PredictorPaletteSize and PredictorPaletteEntries.

Outputs of this process are:

- The variables tableStateSync and tableMPSSync containing the values of the variables pStateIdx and valMps used in the initialization process of context variables and Rice parameter initialization states that are assigned to all syntax elements in clauses 7.3.8.1 through 7.3.8.12, except end_of_slice_segment_flag, end_of_subset_one_bit and pcm_flag.

- The variables tableStatCoeffSync containing the values of the variables StatCoeff[k] used in the initialization process of context variables and Rice parameter initialization states.
- The variables PredictorPaletteSizeSync and tablePredictorPaletteEntriesSync containing the values used in the initialization process of palette predictor variables.

For each context variable, the corresponding entries pStateIdx and valMps of tables tableStateSync and tableMPSSync are initialized to the corresponding pStateIdx and valMps.

For each Rice parameter initialization state k, each entry of the table tableStatCoeffSync is initialized to the corresponding value of StatCoeff[k].

For palette predictor variables, PredictorPaletteSizeSync is initialized to PredictorPaletteSize. For tablePredictorPaletteEntriesSync, each entry is initialized to the corresponding value of PredictorPaletteEntries.

The storage process for context variables is illustrated in the flowchart of Figure 9-4.

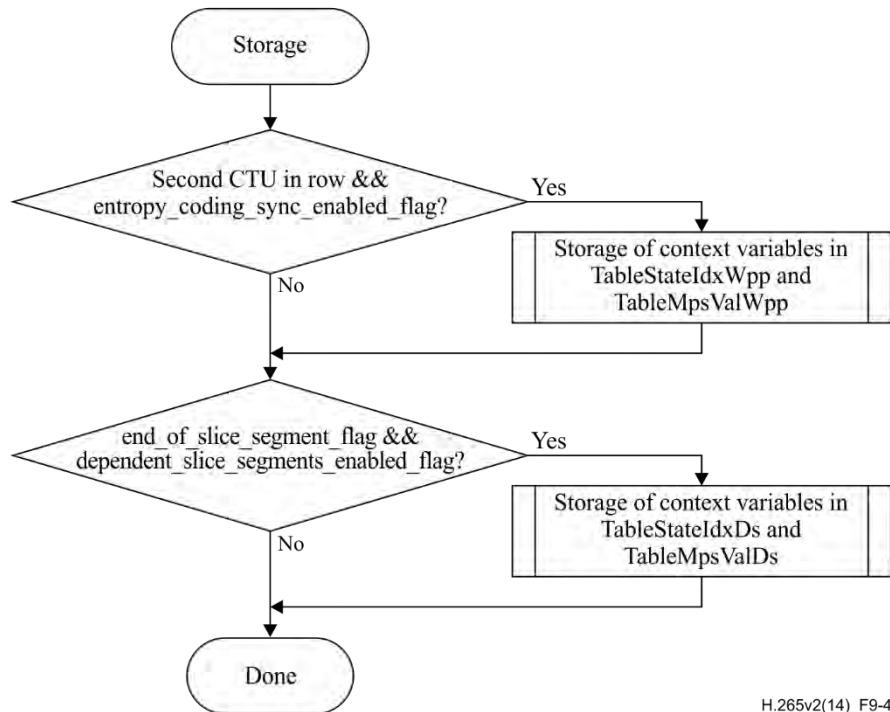

Figure 9-4 – Illustration of CABAC storage process (informative)

9.3.2.5 Synchronization process for context variables, Rice parameter initialization states, and palette predictor variables

Inputs to this process are:

- The variables tableStateSync and tableMPSSync containing the values of the variables pStateIdx and valMps used in the storage process of context variables that are assigned to all syntax elements in clauses 7.3.8.1 through 7.3.8.12, except end_of_slice_segment_flag, end_of_subset_one_bit and pcm_flag.
- The variable tableStatCoeffSync containing the values of the variables StatCoeff[k] used in the storage process of context variables and Rice parameter initialization states.
- The variables PredictorPaletteSizeSync and tablePredictorPaletteEntriesSync containing the values used in the storage process of palette predictor variables.

Outputs of this process are:

- The initialized CABAC context variables indexed by ctxTable and ctxIdx.
- The initialized Rice parameter initialization states StatCoeff indexed by k.
- The palette predictor variables, PredictorPaletteSize and PredictorPaletteEntries.

For each context variable, the corresponding context variables pStateIdx and valMps are initialized to the corresponding entries pStateIdx and valMps of tables tableStateSync and tableMPSSync.

For each Rice parameter initialization state, each variable StatCoeff[k] is initialized to the corresponding entry of tableStatCoeffSync.

For palette predictor variables, PredictorPaletteSize is initialized to PredictorPaletteSizeSync. For PredictorPaletteEntries, each entry is initialized to the corresponding value of tablePredictorPaletteEntriesSync.

9.3.2.6 Initialization process for the arithmetic decoding engine

Outputs of this process are the initialized decoding engine registers ivlCurrRange and ivlOffset both in 16 bit register precision.

The status of the arithmetic decoding engine is represented by the variables ivlCurrRange and ivlOffset. In the initialization procedure of the arithmetic decoding process, ivlCurrRange is set equal to 510 and ivlOffset is set equal to the value returned from read_bits(9) interpreted as a 9 bit binary representation of an unsigned integer with the most significant bit written first.

The bitstream shall not contain data that result in a value of ivlOffset being equal to 510 or 511.

NOTE – The description of the arithmetic decoding engine in this Specification utilizes 16 bit register precision. However, a minimum register precision of 9 bits is required for storing the values of the variables ivlCurrRange and ivlOffset after invocation of the arithmetic decoding process (DecodeBin) as specified in clause 9.3.4.3. The arithmetic decoding process for a binary decision (DecodeDecision) as specified in clause 9.3.4.3.2 and the decoding process for a binary decision before termination (DecodeTerminate) as specified in clause 9.3.4.3.5 require a minimum register precision of 9 bits for the variables ivlCurrRange and ivlOffset. The bypass decoding process for binary decisions (DecodeBypass) as specified in clause 9.3.4.3.4 requires a minimum register precision of 10 bits for the variable ivlOffset and a minimum register precision of 9 bits for the variable ivlCurrRange.

9.3.3 Binarization process

9.3.3.1 General

Input to this process is a request for a syntax element.

Output of this process is the binarization of the syntax element.

Table 9-43 specifies the type of binarization process associated with each syntax element and corresponding inputs.

The specification of the truncated Rice (TR) binarization process, the k-th order Exp-Golomb (EGk) binarization process, limited k-th order Exp-Golomb (EGk) binarization process, the fixed-length (FL) binarization process, and the truncated binary binarization process are given in clauses 9.3.3.2 through 9.3.3.6, respectively. Other binarizations are specified in clauses 9.3.3.7 through 9.3.3.14.

Table 9-43 – Syntax elements and associated binarizations

Syntax structure	Syntax element	Binarization	
		Process	Input parameters
slice_segment_data()	end_of_slice_segment_flag	FL	cMax = 1

	palette_run_suffix	TB	cMax = (PrefixOffset << 1) > PaletteMaxRunMinus1 ? (PaletteMaxRunMinus1 – PrefixOffset) : (PrefixOffset – 1)
delta_qp()	cu_qp_delta_abs	9.3.3.10	-
	cu_qp_delta_sign_flag	FL	cMax = 1
chroma_qp_offset()	cu_chroma_qp_offset_flag	FL	cMax = 1
	cu_chroma_qp_offset_idx	TR	cMax = chroma_qp_offset_list_len_minus1, cRiceParam = 0

9.3.3.2 Truncated Rice binarization process

Input to this process is a request for a truncated Rice (TR) binarization, cMax and cRiceParam.

Output of this process is the TR binarization associating each value symbolVal with a corresponding bin string.

A TR bin string is a concatenation of a prefix bin string and, when present, a suffix bin string.

For the derivation of the prefix bin string, the following applies:

- The prefix value of symbolVal, prefixVal, is derived as follows:

$$\text{prefixVal} = \text{symbolVal} \gg \text{cRiceParam} \quad (9-11)$$

- The prefix of the TR bin string is specified as follows:
 - If prefixVal is less than cMax >> cRiceParam, the prefix bin string is a bit string of length prefixVal + 1 indexed by binIdx. The bins for binIdx less than prefixVal are equal to 1. The bin with binIdx equal to prefixVal is equal to 0. Table 9-44 illustrates the bin strings of this unary binarization for prefixVal.
 - Otherwise, the bin string is a bit string of length cMax >> cRiceParam with all bins being equal to 1.

Table 9-44 – Bin string of the unary binarization (informative)

prefixVal	Bin string					
0	0					
1	1	0				
2	1	1	0			
3	1	1	1	0		
4	1	1	1	1	0	
5	1	1	1	1	1	0
...						
binIdx	0	1	2	3	4	5

When cMax is greater than symbolVal and cRiceParam is greater than 0, the suffix of the TR bin string is present and it is derived as follows:

- The suffix value suffixVal is derived as follows:

$$\text{suffixVal} = \text{symbolVal} - ((\text{prefixVal}) \ll \text{cRiceParam}) \quad (9-12)$$

- The suffix of the TR bin string is specified by invoking the fixed-length (FL) binarization process as specified in clause 9.3.3.5 for suffixVal with a cMax value equal to $(1 \ll \text{cRiceParam}) - 1$.

NOTE – For the input parameter cRiceParam = 0, the TR binarization is exactly a truncated unary binarization and it is always invoked with a cMax value equal to the largest possible value of the syntax element being decoded.

9.3.3.3 k-th order Exp-Golomb binarization process

Inputs to this process is a request for a k-th order Exp-Golomb (EGk) binarization.

Output of this process is the EGk binarization associating each value symbolVal with a corresponding bin string.

The bin string of the EGk binarization process for each value symbolVal is specified as follows, where each call of the function put(X), with X being equal to 0 or 1, adds the binary value X at the end of the bin string:

```

absV = Abs( symbolVal )
stopLoop = 0
do

```

```

    if( absV >= ( 1 << k ) ) {
        put( 1 )
        absV = absV - ( 1 << k )
        k++
    } else {
        put( 0 )
        while( k-- )
            put( ( absV >> k ) & 1 )
        stopLoop = 1
    }
while( !stopLoop )

```

(9-13)

NOTE – The specification for the k-th order Exp-Golomb (EGk) code uses 1's and 0's in reverse meaning for the unary part of the Exp-Golomb code of 0-th order as specified in clause 9.2.

9.3.3.4 Limited EGk binarization process

This process is only invoked when `extended_precision_processing_flag` is equal to 1.

Inputs to this process is a request for a limited EGk binarization, the Rice parameter `riceParam` and the colour component `cIdx`.

Output of this process is the limited EGk binarization associating each value `symbolVal` with a corresponding bin string.

The variables `log2TransformRange` and `maxPrefixExtensionLength` are derived as follows:

$$\text{log2TransformRange} = \text{cIdx} == 0 ? \text{Max}(15, \text{BitDepth}_Y + 6) : \text{Max}(15, \text{BitDepth}_C + 6) \quad (9-14)$$

$$\text{maxPrefixExtensionLength} = 28 - \text{log2TransformRange} \quad (9-15)$$

The bin string of the limited EGk binarization process for each value `symbolVal` is specified as follows, where each call of the function `put(X)`, with `X` being equal to 0 or 1, adds the binary value `X` at the end of the bin string:

```

codeValue = symbolVal >> riceParam
PrefixExtensionLength = 0
while( ( PrefixExtensionLength < maxPrefixExtensionLength ) &&
      ( codeValue > ( ( 2 << PrefixExtensionLength ) - 2 ) ) ) {
    PrefixExtensionLength++
    put( 1 )
}
if( PrefixExtensionLength == maxPrefixExtensionLength )
    escapeLength = log2TransformRange
else {
    escapeLength = PrefixExtensionLength + riceParam
    put( 0 )
}
symbolVal = symbolVal - ( ( ( 1 << PrefixExtensionLength ) - 1 ) << riceParam )
while( ( escapeLength-- ) > 0 )
    put( ( symbolVal >> escapeLength ) & 1 )

```

(9-16)

9.3.3.5 Fixed-length binarization process

Inputs to this process are a request for a fixed-length (FL) binarization and `cMax`.

Output of this process is the FL binarization associating each value `symbolVal` with a corresponding bin string.

FL binarization is constructed by using the `fixedLength`-bit unsigned integer bin string of the symbol value `symbolVal`, where `fixedLength = Ceil(Log2(cMax + 1))`. The indexing of bins for the FL binarization is such that the `binIdx = 0` relates to the most significant bit with increasing values of `binIdx` towards the least significant bit.

9.3.3.6 Truncated Binary (TB) binarization process

Input to this process is a request for a TB binarization for a syntax element with value `synVal` and `cMax`. Output of this process is the TB binarization of the syntax element. The bin string of the TB binarization process of a syntax element `synVal` is specified as follows:

$$\begin{aligned} n &= cMax + 1 \\ k &= \text{Floor}(\text{Log}_2(n)) \\ u &= (1 \ll (k + 1)) - n \end{aligned} \quad (9-17)$$

- If `synVal` is less than `u`, the TB bin string is derived by invoking the FL binarization process specified in clause 9.3.3.5 for `synVal` with a `cMax` value equal to $(1 \ll k) - 1$.
- Otherwise (`synVal` is greater than or equal to `u`), the TB bin string is derived by invoking the FL binarization process specified in clause 9.3.3.5 for $(\text{synVal} + u)$ with a `cMax` value equal to $(1 \ll (k + 1)) - 1$.

9.3.3.7 Binarization process for `part_mode`

Inputs to this process are a request for a binarization for the syntax element `part_mode`, a luma location (x_{Cb}, y_{Cb}) , specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture and a variable `log2CbSize` specifying the current luma coding block size.

Output of this process is the binarization of the syntax element.

The binarization for the syntax element `part_mode` is specified in Table 9-45 depending on the values of `CuPredMode[xCb][yCb]` and `log2CbSize`.

Table 9-45 – Binarization for `part_mode`

CuPredMode[xCb][yCb]	part_mode	PartMode	Bin string			
			log2CbSize > MinCbLog2SizeY		log2CbSize == MinCbLog2SizeY	
			!amp_enabled_flag	amp_enabled_flag	log2CbSize == 3	log2CbSize > 3
MODE_INTRA	0	PART_2Nx2N	-	-	1	1
	1	PART_NxN	-	-	0	0
MODE_INTER	0	PART_2Nx2N	1	1	1	1
	1	PART_2NxN	01	011	01	01
	2	PART_Nx2N	00	001	00	001
	3	PART_NxN	-	-	-	000
	4	PART_2NxN	-	0100	-	-
	5	PART_2NxND	-	0101	-	-
	6	PART_nLx2N	-	0000	-	-
	7	PART_nRx2N	-	0001	-	-

9.3.3.8 Binarization process for `intra_chroma_pred_mode`

Input to this process is a request for a binarization for the syntax element `intra_chroma_pred_mode`.

Output of this process is the binarization of the syntax element.

The binarization for the syntax element `intra_chroma_pred_mode` is specified in Table 9-46.

Table 9-46 – Binarization for intra_chroma_pred_mode

Value of intra_chroma_pred_mode	Bin string
4	0
0	100
1	101
2	110
3	111

9.3.3.9 Binarization process for inter_pred_idc

Inputs to this process are a request for a binarization for the syntax element `inter_pred_idc`, the current luma prediction block width `nPbW` and the current luma prediction block height `nPbH`.

Output of this process is the binarization of the syntax element.

The binarization for the syntax element `inter_pred_idc` is specified in Table 9-47.

Table 9-47 – Binarization for inter_pred_idc

Value of inter_pred_idc	Name of inter_pred_idc	Bin string	
		(nPbW + nPbH) != 12	(nPbW + nPbH) == 12
0	PRED_L0	00	0
1	PRED_L1	01	1
2	PRED_BI	1	-

9.3.3.10 Binarization process for cu_qp_delta_abs

Input to this process is a request for a binarization for the syntax element `cu_qp_delta_abs`.

Output of this process is the binarization of the syntax element.

The binarization of the syntax element `cu_qp_delta_abs` is a concatenation of a prefix bin string and (when present) a suffix bin string.

For the derivation of the prefix bin string, the following applies:

- The prefix value of `cu_qp_delta_abs`, `prefixVal`, is derived as follows:

$$\text{prefixVal} = \text{Min}(\text{cu_qp_delta_abs}, 5) \quad (9-18)$$

- The prefix bin string is specified by invoking the TR binarization process as specified in clause 9.3.3.2 for `prefixVal` with `cMax = 5` and `cRiceParam = 0`.

When `prefixVal` is greater than 4, the suffix bin string is present and it is derived as follows:

- The suffix value of `cu_qp_delta_abs`, `suffixVal`, is derived as follows:

$$\text{suffixVal} = \text{cu_qp_delta_abs} - 5 \quad (9-19)$$

- The suffix bin string is specified by invoking the k-th order EGk binarization process as specified in clause 9.3.3.3 for `suffixVal` with the Exp-Golomb order `k` set equal to 0.

9.3.3.11 Binarization process for coeff_abs_level_remaining[]

Input to this process is a request for a binarization for the syntax element `coeff_abs_level_remaining[n]`, the current sub-block scan index `i`, `baseLevel`, the colour component `cIdx` and the luma location (`x0`, `y0`) specifying the top-left sample of the current luma transform block relative to the top-left luma sample of the picture.

Output of this process is the binarization of the syntax element.

Depending on the value of `persistent_rice_adaptation_enabled_flag`, the following applies:

- If `persistent_rice_adaptation_enabled_flag` is equal to 0, the variable `initRiceValue` is set equal to 0.
- Otherwise (`persistent_rice_adaptation_enabled_flag` is equal to 1), the following applies:
 - The variable `sbType` is derived as follows:

- If `transform_skip_flag[x0][y0][cIdx]` is equal to 0 and `cu_transquant_bypass_flag` is equal to 0, the following applies:

$$sbType = 2 * (cIdx == 0 ? 1 : 0) \quad (9-20)$$

- Otherwise, the following applies:

$$sbType = 2 * (cIdx == 0 ? 1 : 0) + 1 \quad (9-21)$$

- The variable `initRiceValue` is derived as follows:

$$initRiceValue = StatCoeff[sbType] / 4 \quad (9-22)$$

- If this process is invoked for the first time for the current sub-block scan index `i`, `StatCoeff[sbType]` is modified as follows:

$$\begin{aligned} & \text{if(coeff_abs_level_remaining[n] } \geq (3 \ll (StatCoeff[sbType] / 4))) \\ & \quad StatCoeff[sbType]++ \\ & \text{else if(} 2 * \text{coeff_abs_level_remaining[n]} < (1 \ll (StatCoeff[sbType] / 4)) \ \&\& \\ & \quad StatCoeff[sbType] > 0) \\ & \quad StatCoeff[sbType]-- \end{aligned} \quad (9-23)$$

The variables `cLastAbsLevel` and `cLastRiceParam` are derived as follows:

- If this process is invoked for the first time for the current sub-block scan index `i`, `cLastAbsLevel` is set equal to 0 and `cLastRiceParam` is set equal to `initRiceValue`.
- Otherwise (this process is not invoked for the first time for the current sub-block scan index `i`), `cLastAbsLevel` and `cLastRiceParam` are set equal to the values of `cAbsLevel` and `cRiceParam`, respectively, that have been derived during the last invocation of the binarization process for the syntax element `coeff_abs_level_remaining[n]` as specified in this clause.

The variable `cAbsLevel` is set equal to `baseLevel + coeff_abs_level_remaining[n]`.

The variable `cRiceParam` is derived from `cLastAbsLevel` and `cLastRiceParam` as follows:

- If `persistent_rice_adaptation_enabled_flag` is equal to 0, the following applies:

$$\begin{aligned} cRiceParam = \\ \text{Min(cLastRiceParam + (cLastAbsLevel } > (3 * (1 \ll cLastRiceParam)) ? 1 : 0), 4) \end{aligned} \quad (9-24)$$

- Otherwise (`persistent_rice_adaptation_enabled_flag` is equal to 1), the following applies:

$$cRiceParam = cLastRiceParam + (cLastAbsLevel > (3 * (1 \ll cLastRiceParam)) ? 1 : 0) \quad (9-25)$$

The variable `cMax` is derived from `cRiceParam` as:

$$cMax = 4 \ll cRiceParam \quad (9-26)$$

The binarization of the syntax element `coeff_abs_level_remaining[n]` is a concatenation of a prefix bin string and (when present) a suffix bin string.

For the derivation of the prefix bin string, the following applies:

- The prefix value of `coeff_abs_level_remaining[n]`, `prefixVal`, is derived as follows:

$$prefixVal = \text{Min(cMax, coeff_abs_level_remaining[n])} \quad (9-27)$$

- The prefix bin string is specified by invoking the TR binarization process as specified in clause 9.3.3.2 for prefixVal with the variables cMax and cRiceParam as inputs.

When the prefix bin string is equal to the bit string of length 4 with all bits equal to 1, the suffix bin string is present and it is derived as follows:

- The suffix value of coeff_abs_level_remaining[n], suffixVal, is derived as follows:

$$\text{suffixVal} = \text{coeff_abs_level_remaining}[n] - \text{cMax} \quad (9-28)$$

- If extended_precision_processing_flag is equal to 0, the suffix bin string is specified by invoking the k-th order EGk binarization process as specified in clause 9.3.3.3 for the binarization of suffixVal with the Exp-Golomb order k set equal to cRiceParam + 1.
- Otherwise (extended_precision_processing_flag is equal to 1), the suffix bin string is specified by invoking the limited k-th order EGk binarization process as specified in clause 9.3.3.4 for the binarization of suffixVal with the variable riceParam set equal to cRiceParam + 1 and the colour component cIdx.

9.3.3.12 Binarization process for palette_escape_val

Input to this process is a request for a binarization for the syntax element palette_escape_val, cu_transquant_bypass_flag and colour component index cIdx.

Output of this process is the binarization of palette_escape_val.

The variable bitDepth is derived as follows:

$$\text{bitDepth} = (\text{cIdx} == 0) ? \text{BitDepth}_Y : \text{BitDepth}_C \quad (9-29)$$

The binarization of palette_escape_val is derived as follows:

- If cu_transquant_bypass_flag is equal to 1, the binarization of palette_escape_val is derived by invoking the FL binarization process specified in clause 9.3.3.5 with the input parameter set to $(1 \ll \text{bitdepth}) - 1$.

Otherwise (cu_transquant_bypass_flag is equal to 0), the binarization of palette_escape_val is derived by invoking the k-th order Exp-Golomb binarization process specified in clause 9.3.3.3 with k set equal to 3.

9.3.3.13 Binarization process for palette_idx_idc

Input to this process is a request for a binarization for the syntax element palette_idx_idc and the variable MaxPaletteIndex.

Output of this process is the binarization of the syntax element.

The variable cMax is derived as follows:

- If this process is invoked for the first time for the current block, cMax is set equal to MaxPaletteIndex.
- Otherwise (this process is not invoked for the first time for the current block), cMax is set equal to MaxPaletteIndex minus 1.

The binarization for the palette_idx_idc is derived by invoking the TB binarization process specified in clause 9.3.3.6 with cMax.

9.3.3.14 Binarization process for num_palette_indices_minus1

Input to this process is a request for a binarization for the syntax element num_palette_indices_minus1, and MaxPaletteIndex.

Output of this process is the binarization of the syntax element.

The variable cRiceParam is derived as follows:

$$\text{cRiceParam} = 3 + ((\text{MaxPaletteIndex} + 1) \gg 3) \quad (9-30)$$

The variable cMax is derived from cRiceParam as:

$$\text{cMax} = 4 \ll \text{cRiceParam} \quad (9-31)$$

The binarization of the syntax element num_palette_indices_minus1 is a concatenation of a prefix bin string and (when present) a suffix bin string.

For the derivation of the prefix bin string, the following applies:

- The prefix value of `num_palette_indices_minus1`, `prefixVal`, is derived as follows:

$$\text{prefixVal} = \text{Min}(\text{cMax}, \text{num_palette_indices_minus1}) \quad (9-32)$$

- The prefix bin string is specified by invoking the TR binarization process as specified in clause 9.3.3.2 for `prefixVal` with the variables `cMax` and `cRiceParam` as inputs.

When the prefix bin string is equal to the bit string of length 4 with all bits equal to 1, the suffix bin string is present and it is derived as follows:

- The suffix value of `num_palette_indices_minus1`, `suffixVal`, is derived as follows:

$$\text{suffixVal} = \text{num_palette_indices_minus1} - \text{cMax} \quad (9-33)$$

The suffix bin string is specified by invoking the k-th order EGk binarization process as specified in clause 9.3.3.3 for the binarization of `suffixVal` with the Exp-Golomb order `k` set equal to `cRiceParam + 1`.

9.3.4 Decoding process flow

9.3.4.1 General

Inputs to this process are all bin strings of the binarization of the requested syntax element as specified in clause 9.3.3.

Output of this process is the value of the syntax element.

This process specifies how each bin of a bin string is parsed for each syntax element. After parsing each bin, the resulting bin string is compared to all bin strings of the binarization of the syntax element and the following applies:

- If the bin string is equal to one of the bin strings, the corresponding value of the syntax element is the output.
- Otherwise (the bin string is not equal to one of the bin strings), the next bit is parsed.

While parsing each bin, the variable `binIdx` is incremented by 1 starting with `binIdx` being set equal to 0 for the first bin.

The parsing of each bin is performed by invoking the derivation process for `ctxTable`, `ctxIdx`, and `bypassFlag` as specified in clause 9.3.4.2 with `binIdx` as input and `ctxTable`, `ctxIdx` and `bypassFlag` as outputs.

NOTE – As a consequence of invoking the process specified in clause 9.3.4.2, the arithmetic decoding process as specified in clause 9.3.4.3 is invoked with `ctxTable`, `ctxIdx` and `bypassFlag` as inputs and the value of the bin as output.

9.3.4.2 Derivation process for `ctxTable`, `ctxIdx` and `bypassFlag`

9.3.4.2.1 General

Input to this process is the position of the current bin within the bin string, `binIdx`.

Outputs of this process are `ctxTable`, `ctxIdx` and `bypassFlag`.

The values of `ctxTable`, `ctxIdx` and `bypassFlag` are derived as follows based on the entries for `binIdx` of the corresponding syntax element in Table 9-48:

- If the entry in Table 9-48 is not equal to "bypass", "terminate" or "na", the values of `binIdx` are decoded by invoking the `DecodeDecision` process as specified in clause 9.3.4.3.2 and the following applies:
 - `ctxTable` is specified in Table 9-4.
 - The variable `ctxInc` is specified by the corresponding entry in Table 9-48 and when more than one value is listed in Table 9-48 for a `binIdx`, the assignment process for `ctxInc` for that `binIdx` is further specified in the clauses given in parenthesis.
 - The variable `ctxIdxOffset` is specified by the lowest value of `ctxIdx` in Table 9-4 depending on the current value of `initType`.
 - `ctxIdx` is set equal to the sum of `ctxInc` and `ctxIdxOffset`.
 - `bypassFlag` is set equal to 0.
- Otherwise, if the entry in Table 9-48 is equal to "bypass", the values of `binIdx` are decoded by invoking the `DecodeBypass` process as specified in clause 9.3.4.3.4 and the following applies:
 - `ctxTable` is set equal to 0.

- ctxIdx is set equal to 0.
- bypassFlag is set equal to 1.
- Otherwise, if the entry in Table 9-48 is equal to "terminate", the values of binIdx are decoded by invoking the DecodeTerminate process as specified in clause 9.3.4.3.5 and the following applies:
 - ctxTable is set equal to 0.
 - ctxIdx is set equal to 0.
 - bypassFlag is set equal to 0.
- Otherwise (the entry in Table 9-48 is equal to "na"), the values of binIdx do not occur for the corresponding syntax element.

9.3.4.2.2 Derivation process of ctxInc using left and above syntax elements

Input to this process is the luma location (x0, y0) specifying the top-left luma sample of the current luma block relative to the top-left sample of the current picture.

Output of this process is ctxInc.

The location (xNbL, yNbL) is set equal to (x0 – 1, y0) and the variable availableL, specifying the availability of the block located directly to the left of the current block, is derived by invoking the availability derivation process for a block in z-scan order as specified in clause 6.4.1 with the location (xCurr, yCurr) set equal to (x0, y0) and the neighbouring location (xNbY, yNbY) set equal to (xNbL, yNbL) as inputs, and the output is assigned to availableL.

The location (xNbA, yNbA) is set equal to (x0, y0 – 1) and the variable availableA specifying the availability of the coding block located directly above the current block, is derived by invoking the availability derivation process for a block in z-scan order as specified in clause 6.4.1 with the location (xCurr, yCurr) set equal to (x0, y0) and the neighbouring location (xNbY, yNbY) set equal to (xNbA, yNbA) as inputs, and the output is assigned to availableA.

The assignment of ctxInc for the syntax elements split_cu_flag[x0][y0] and cu_skip_flag[x0][y0] is specified in Table 9-49.

Table 9-49 – Specification of ctxInc using left and above syntax elements

Syntax element	condL	condA	ctxInc
split_cu_flag[x0][y0]	CtDepth[xNbL][yNbL] > cqtDepth	CtDepth[xNbA][yNbA] > cqtDepth	(condL && availableL) + (condA && availableA)
cu_skip_flag[x0][y0]	cu_skip_flag[xNbL][yNbL]	cu_skip_flag[xNbA][yNbA]	(condL && availableL) + (condA && availableA)

9.3.4.2.3 Derivation process of ctxInc for the syntax elements last_sig_coeff_x_prefix and last_sig_coeff_y_prefix

Inputs to this process are the variable binIdx, the colour component index cIdx and the transform block size log2TrafoSize.

Output of this process is the variable ctxInc.

The variables ctxOffset and ctxShift are derived as follows:

- If cIdx is equal to 0, ctxOffset is set equal to $3 * (\log_2 \text{TrafoSize} - 2) + ((\log_2 \text{TrafoSize} - 1) \gg 2)$ and ctxShift is set equal to $(\log_2 \text{TrafoSize} + 1) \gg 2$.
- Otherwise (cIdx is greater than 0), ctxOffset is set equal to 15 and ctxShift is set equal to $\log_2 \text{TrafoSize} - 2$.

The variable ctxInc is derived as follows:

$$\text{ctxInc} = (\text{binIdx} \gg \text{ctxShift}) + \text{ctxOffset} \quad (9-34)$$

9.3.4.2.4 Derivation process of ctxInc for the syntax element coded_sub_block_flag

Inputs to this process are the colour component index cIdx, the current sub-block scan location (xS, yS), the previously decoded bins of the syntax element coded_sub_block_flag and the transform block size log2TrafoSize.

Output of this process is the variable `ctxInc`.

The variable `csbfCtx` is derived using the current location (`xS`, `yS`), two previously decoded bins of the syntax element `coded_sub_block_flag` in scan order and the transform block size `log2TrafoSize`, as follows:

- `csbfCtx` is initialized with 0 as follows:

$$\text{csbfCtx} = 0 \quad (9-35)$$

- When `xS` is less than $(1 \ll (\log_2\text{TrafoSize} - 2)) - 1$, `csbfCtx` is modified as follows:

$$\text{csbfCtx} += \text{coded_sub_block_flag}[xS + 1][yS] \quad (9-36)$$

- When `yS` is less than $(1 \ll (\log_2\text{TrafoSize} - 2)) - 1$, `csbfCtx` is modified as follows:

$$\text{csbfCtx} += \text{coded_sub_block_flag}[xS][yS + 1] \quad (9-37)$$

The context index increment `ctxInc` is derived using the colour component index `cIdx` and `csbfCtx` as follows:

- If `cIdx` is equal to 0, `ctxInc` is derived as follows:

$$\text{ctxInc} = \text{Min}(\text{csbfCtx}, 1) \quad (9-38)$$

- Otherwise (`cIdx` is greater than 0), `ctxInc` is derived as follows:

$$\text{ctxInc} = 2 + \text{Min}(\text{csbfCtx}, 1) \quad (9-39)$$

9.3.4.2.5 Derivation process of `ctxInc` for the syntax element `sig_coeff_flag`

Inputs to this process are the colour component index `cIdx`, the luma location (`x0`, `y0`) specifying the top-left sample of the current transform block relative to the top-left sample of the current picture, the current coefficient scan location (`xC`, `yC`), the scan order index `scanIdx` and the transform block size `log2TrafoSize`.

Output of this process is the variable `ctxInc`.

The variable `sigCtx` depends on the current location (`xC`, `yC`), the colour component index `cIdx`, the value of `transform_skip_flag`, the value of `cu_transquant_bypass_flag`, the transform block size and previously decoded bins of the syntax element `coded_sub_block_flag`. For the derivation of `sigCtx`, the following applies:

- If `transform_skip_context_enabled_flag` is equal to 1 and either or both `transform_skip_flag[x0][y0][cIdx]` is equal to 1 or `cu_transquant_bypass_flag` is equal to 1, `sigCtx` is derived as follows:

$$\text{sigCtx} = (\text{cIdx} == 0) ? 42 : 16 \quad (9-40)$$

- Otherwise, if `log2TrafoSize` is equal to 2, `sigCtx` is derived using `ctxIdxMap[]` specified in Table 9-50 as follows:

$$\text{sigCtx} = \text{ctxIdxMap}[(yC \ll 2) + xC] \quad (9-41)$$

- Otherwise, if `xC + yC` is equal to 0, `sigCtx` is derived as follows:

$$\text{sigCtx} = 0 \quad (9-42)$$

- Otherwise, `sigCtx` is derived using previous values of `coded_sub_block_flag` as follows:

- The sub-block location (`xS`, `yS`) is set equal to (`xC >> 2`, `yC >> 2`).

- The variable `prevCsbF` is set equal to 0.

- When `xS` is less than $(1 \ll (\log_2\text{TrafoSize} - 2)) - 1$, the following applies:

$$\text{prevCsbF} += \text{coded_sub_block_flag}[xS + 1][yS] \quad (9-43)$$

- When `yS` is less than $(1 \ll (\log_2\text{TrafoSize} - 2)) - 1$, the following applies:

$$\text{prevCsbF} += (\text{coded_sub_block_flag}[xS][yS + 1] \ll 1) \quad (9-44)$$

- The inner sub-block location (`xP`, `yP`) is set equal to (`xC & 3`, `yC & 3`).

- The variable sigCtx is derived as follows:

- If prevCsbF is equal to 0, the following applies:

$$\text{sigCtx} = (\text{xP} + \text{yP} == 0) ? 2 : (\text{xP} + \text{yP} < 3) ? 1 : 0 \quad (9-45)$$

- Otherwise, if prevCsbF is equal to 1, the following applies:

$$\text{sigCtx} = (\text{yP} == 0) ? 2 : (\text{yP} == 1) ? 1 : 0 \quad (9-46)$$

- Otherwise, if prevCsbF is equal to 2, the following applies:

$$\text{sigCtx} = (\text{xP} == 0) ? 2 : (\text{xP} == 1) ? 1 : 0 \quad (9-47)$$

- Otherwise (prevCsbF is equal to 3), the following applies:

$$\text{sigCtx} = 2 \quad (9-48)$$

- The variable sigCtx is modified as follows:

- If cIdx is equal to 0, the following applies:

- When (xS + yS) is greater than 0, the following applies:

$$\text{sigCtx} += 3 \quad (9-49)$$

- The variable sigCtx is modified as follows:

- If log2TrafoSize is equal to 3, the following applies:

$$\text{sigCtx} += (\text{scanIdx} == 0) ? 9 : 15 \quad (9-50)$$

- Otherwise, the following applies:

$$\text{sigCtx} += 21 \quad (9-51)$$

- Otherwise (cIdx is greater than 0), the following applies:

- If log2TrafoSize is equal to 3, the following applies:

$$\text{sigCtx} += 9 \quad (9-52)$$

- Otherwise, the following applies:

$$\text{sigCtx} += 12 \quad (9-53)$$

The context index increment ctxInc is derived using the colour component index cIdx and sigCtx as follows:

- If cIdx is equal to 0, ctxInc is derived as follows:

$$\text{ctxInc} = \text{sigCtx} \quad (9-54)$$

- Otherwise (cIdx is greater than 0), ctxInc is derived as follows:

$$\text{ctxInc} = 27 + \text{sigCtx} \quad (9-55)$$

Table 9-50 – Specification of ctxIdxMap[i]

i	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14
ctxIdxMap[i]	0	1	4	5	2	3	4	5	6	6	8	8	7	7	8

9.3.4.2.6 Derivation process of ctxInc for the syntax element coeff_abs_level_greater1_flag

Inputs to this process are the colour component index cIdx, the current sub-block scan index i and the current coefficient scan index n within the current sub-block.

Output of this process is the variable ctxInc.

The variable ctxSet specifies the current context set and for its derivation the following applies:

- If this process is invoked for the first time for the current sub-block scan index i, the following applies:
 - The variable ctxSet is initialized as follows:
 - If the current sub-block scan index i is equal to 0 or cIdx is greater than 0, the following applies:
$$\text{ctxSet} = 0 \quad (9-56)$$
 - Otherwise (i is greater than 0 and cIdx is equal to 0), the following applies:
$$\text{ctxSet} = 2 \quad (9-57)$$
 - The variable lastGreater1Ctx is derived as follows:
 - If the current sub-block with scan index i is the first one to be processed in this clause for the current transform block, the variable lastGreater1Ctx is set equal to 1.
 - Otherwise, the following applies:
 - The variable lastGreater1Ctx is set equal to the value of greater1Ctx that has been derived during the last invocation of the process specified in this clause for a previous sub-block.
 - When lastGreater1Ctx is greater than 0, the variable lastGreater1Flag is set equal to the value of the syntax element coeff_abs_level_greater1_flag that has been used during the last invocation of the process specified in this clause for a previous sub-block and lastGreater1Ctx is modified as follows:
 - If lastGreater1Flag is equal to 1, lastGreater1Ctx is set equal to 0.
 - Otherwise (lastGreater1Flag is equal to 0), lastGreater1Ctx is incremented by 1.
 - When lastGreater1Ctx is equal to 0, ctxSet is incremented by one as follows:
$$\text{ctxSet} = \text{ctxSet} + 1 \quad (9-58)$$
 - The variable greater1Ctx is set equal to 1.
- Otherwise (this process is not invoked for the first time for the current sub-block scan index i), the following applies:
 - The variable ctxSet is set equal to the variable ctxSet that has been derived during the last invocation of the process specified in this clause.
 - The variable greater1Ctx is set equal to the variable greater1Ctx that has been derived during the last invocation of the process specified in this clause.
 - When greater1Ctx is greater than 0, the variable lastGreater1Flag is set equal to the syntax element coeff_abs_level_greater1_flag that has been used during the last invocation of the process specified in this clause and greater1Ctx is modified as follows:
 - If lastGreater1Flag is equal to 1, greater1Ctx is set equal to 0.
 - Otherwise (lastGreater1Flag is equal to 0), greater1Ctx is incremented by 1.

The context index increment ctxInc is derived using the current context set ctxSet and the current context greater1Ctx as follows:

$$\text{ctxInc} = (\text{ctxSet} * 4) + \text{Min}(3, \text{greater1Ctx}) \quad (9-59)$$

When cIdx is greater than 0, ctxInc is modified as follows:

$$\text{ctxInc} = \text{ctxInc} + 16 \quad (9-60)$$

9.3.4.2.7 Derivation process of ctxInc for the syntax element coeff_abs_level_greater2_flag

Inputs to this process are the colour component index cIdx, the current sub-block scan index i and the current coefficient scan index n within the current sub-block.

Output of this process is the variable ctxInc.

The variable ctxSet specifies the current context set and is set equal to the value of the variable ctxSet that has been derived in clause 9.3.4.2.6 for the same subset i.

The context index increment ctxInc is set equal to the variable ctxSet as follows:

$$\text{ctxInc} = \text{ctxSet} \quad (9-61)$$

When cIdx is greater than 0, ctxInc is modified as follows:

$$\text{ctxInc} = \text{ctxInc} + 4 \quad (9-62)$$

9.3.4.2.8 Derivation process of ctxInc for the syntax element palette_run_prefix

Inputs to this process are the bin index binIdx and the syntax elements copy_above_palette_indices_flag and palette_idx_idc.

Output of this process is the variable ctxInc.

The variable ctxInc is derived as follows:

- If copy_above_palette_indices_flag is equal to 0 and binIdx is equal to 0, ctxInc is derived as follows:

$$\text{ctxInc} = (\text{palette_idx_idc} < 1) ? 0 : ((\text{palette_idx_idc} < 3) ? 1 : 2) \quad (9-63)$$

- Otherwise, ctxInc is provided by Table 9-51.

Table 9-51 – Specification of ctxIdxMap[copy_above_palette_indices_flag][binIdx]

binIdx	0	1	2	3	4	> 4
copy_above_palette_indices_flag == 1	5	6	6	7	7	bypass
copy_above_palette_indices_flag == 0	0, 1, 2	3	3	4	4	bypass

9.3.4.3 Arithmetic decoding process

9.3.4.3.1 General

Inputs to this process are ctxTable, ctxIdx and bypassFlag, as derived in clause 9.3.4.2, and the state variables ivlCurrRange and ivlOffset of the arithmetic decoding engine.

Output of this process is the value of the bin.

Figure 9-5 illustrates the whole arithmetic decoding process for a single bin. For decoding the value of a bin, the context index table ctxTable and the ctxIdx are passed to the arithmetic decoding process DecodeBin(ctxTable, ctxIdx), which is specified as follows:

- If bypassFlag is equal to 1, DecodeBypass() as specified in clause 9.3.4.3.4 is invoked.
- Otherwise, if bypassFlag is equal to 0, ctxTable is equal to 0 and ctxIdx is equal to 0, DecodeTerminate() as specified in clause 9.3.4.3.5 is invoked.
- Otherwise (bypassFlag is equal to 0 and ctxTable is not equal to 0), DecodeDecision() as specified in clause 9.3.4.3.2 is invoked.

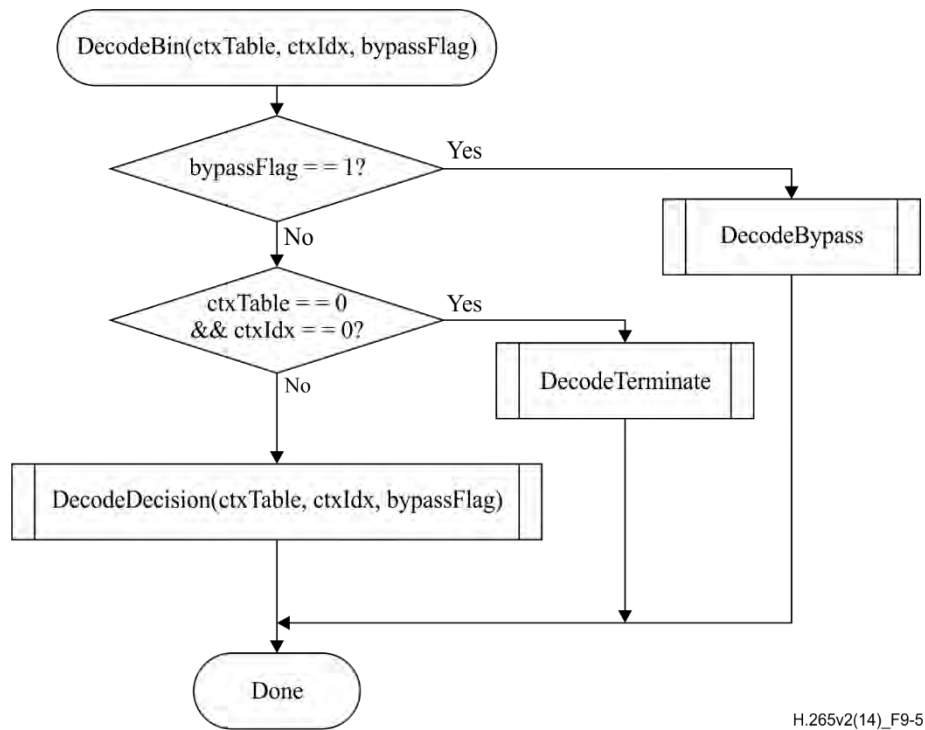

Figure 9-5 – Overview of the arithmetic decoding process for a single bin (informative)

NOTE – Arithmetic coding is based on the principle of recursive interval subdivision. Given a probability estimation $p(0)$ and $p(1) = 1 - p(0)$ of a binary decision $(0, 1)$, an initially given code sub-interval with the range $ivlCurrRange$ will be subdivided into two sub-intervals having range $p(0) * ivlCurrRange$ and $ivlCurrRange - p(0) * ivlCurrRange$, respectively. Depending on the decision, which has been observed, the corresponding sub-interval will be chosen as the new code interval, and a binary code string pointing into that interval will represent the sequence of observed binary decisions. It is useful to distinguish between the most probable symbol (MPS) and the least probable symbol (LPS), so that binary decisions have to be identified as either MPS or LPS, rather than 0 or 1. Given this terminology, each context is specified by the probability $plps$ of the LPS and the value of MPS ($valMps$), which is either 0 or 1. The arithmetic core engine in this Specification has three distinct properties:

- The probability estimation is performed by means of a finite-state machine with a table-based transition process between 64 different representative probability states $\{plps(pStateIdx) \mid 0 \leq pStateIdx < 64\}$ for the LPS probability $plps$. The numbering of the states is arranged in such a way that the probability state with index $pStateIdx = 0$ corresponds to an LPS probability value of 0.5, with decreasing LPS probability towards higher state indices.
- The range $ivlCurrRange$ representing the state of the coding engine is quantized to a small set $\{Q_1, \dots, Q_4\}$ of pre-set quantization values prior to the calculation of the new interval range. Storing a table containing all 64×4 pre-computed product values of $Q_i * plps(pStateIdx)$ allows a multiplication-free approximation of the product $ivlCurrRange * plps(pStateIdx)$.
- For syntax elements or parts thereof for which an approximately uniform probability distribution is assumed to be given a separate simplified encoding and decoding bypass process is used.

9.3.4.3.2 Arithmetic decoding process for a binary decision

9.3.4.3.2.1 General

Inputs to this process are the variables $ctxTable$, $ctxIdx$, $ivlCurrRange$ and $ivlOffset$.

Outputs of this process are the decoded value $binVal$ and the updated variables $ivlCurrRange$ and $ivlOffset$.

Figure 9-6 shows the flowchart for decoding a single decision ($DecodeDecision$):

1. The value of the variable $ivlLpsRange$ is derived as follows:

- Given the current value of $ivlCurrRange$, the variable $qRangeIdx$ is derived as follows:

$$qRangeIdx = (ivlCurrRange \gg 6) \& 3 \quad (9-64)$$

- Given $qRangeIdx$ and $pStateIdx$ associated with $ctxTable$ and $ctxIdx$, the value of the variable $rangeTabLps$ as specified in Table 9-52 is assigned to $ivlLpsRange$:

$$ivlLpsRange = rangeTabLps[pStateIdx][qRangeIdx] \quad (9-65)$$

2. The variable `ivlCurrRange` is set equal to `ivlCurrRange – ivlLpsRange` and the following applies:
 - If `ivlOffset` is greater than or equal to `ivlCurrRange`, the variable `binVal` is set equal to `1 – valMps`, `ivlOffset` is decremented by `ivlCurrRange` and `ivlCurrRange` is set equal to `ivlLpsRange`.
 - Otherwise, the variable `binVal` is set equal to `valMps`.

Given the value of `binVal`, the state transition is performed as specified in clause 9.3.4.3.2.2. Depending on the current value of `ivlCurrRange`, renormalization is performed as specified in clause 9.3.4.3.3.

9.3.4.3.2.2 State transition process

Inputs to this process are the current `pStateIdx`, the decoded value `binVal` and `valMps` values of the context variable associated with `ctxTable` and `ctxIdx`.

Outputs of this process are the updated `pStateIdx` and `valMps` of the context variable associated with `ctxIdx`.

Depending on the decoded value `binVal`, the update of the two variables `pStateIdx` and `valMps` associated with `ctxIdx` is derived as follows:

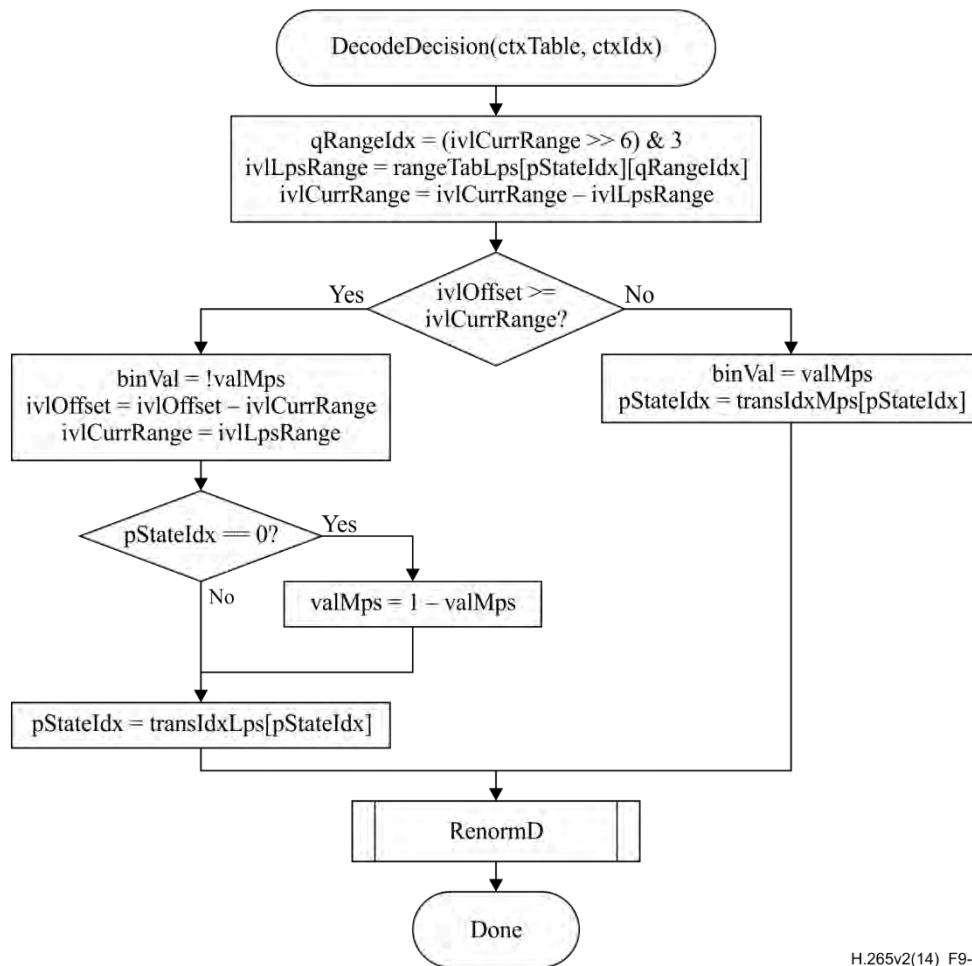

```

if( binVal == valMps )
    pStateIdx = transIdxMps( pStateIdx )
else {
    if( pStateIdx == 0 )
        valMps = 1 – valMps
    pStateIdx = transIdxLps( pStateIdx )
}

```

(9-66)

Table 9-53 specifies the transition rules `transIdxMps()` and `transIdxLps()` after decoding the value of `valMps` and `1 – valMps`, respectively.

9.3.4.3.3 Renormalization process in the arithmetic decoding engine

Inputs to this process are bits from slice segment data and the variables ivlCurrRange and ivlOffset.

Outputs of this process are the updated variables ivlCurrRange and ivlOffset.

A flowchart of the renormalization is shown in Figure 9-7. The current value of ivlCurrRange is first compared to 256 and then the following applies:

- If ivlCurrRange is greater than or equal to 256, no renormalization is needed and the RenormD process is finished;
- Otherwise (ivlCurrRange is less than 256), the renormalization loop is entered. Within this loop, the value of ivlCurrRange is doubled, i.e., left-shifted by 1 and a single bit is shifted into ivlOffset by using read_bits(1).

The bitstream shall not contain data that result in a value of ivlOffset being greater than or equal to ivlCurrRange upon completion of this process.

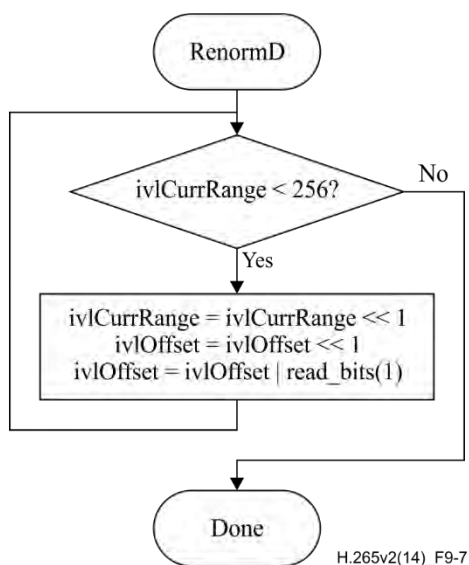

Figure 9-7 – Flowchart of renormalization

9.3.4.3.4 Bypass decoding process for binary decisions

Inputs to this process are bits from slice segment data and the variables `ivlCurrRange` and `ivlOffset`.

Outputs of this process are the updated variable `ivlOffset` and the decoded value `binVal`.

The bypass decoding process is invoked when `bypassFlag` is equal to 1. Figure 9-8 shows a flowchart of the corresponding process.

First, the value of `ivlOffset` is doubled, i.e., left-shifted by 1 and a single bit is shifted into `ivlOffset` by using `read_bits(1)`. Then, the value of `ivlOffset` is compared to the value of `ivlCurrRange` and then the following applies:

- If `ivlOffset` is greater than or equal to `ivlCurrRange`, the variable `binVal` is set equal to 1 and `ivlOffset` is decremented by `ivlCurrRange`.
- Otherwise (`ivlOffset` is less than `ivlCurrRange`), the variable `binVal` is set equal to 0.

The bitstream shall not contain data that result in a value of `ivlOffset` being greater than or equal to `ivlCurrRange` upon completion of this process.

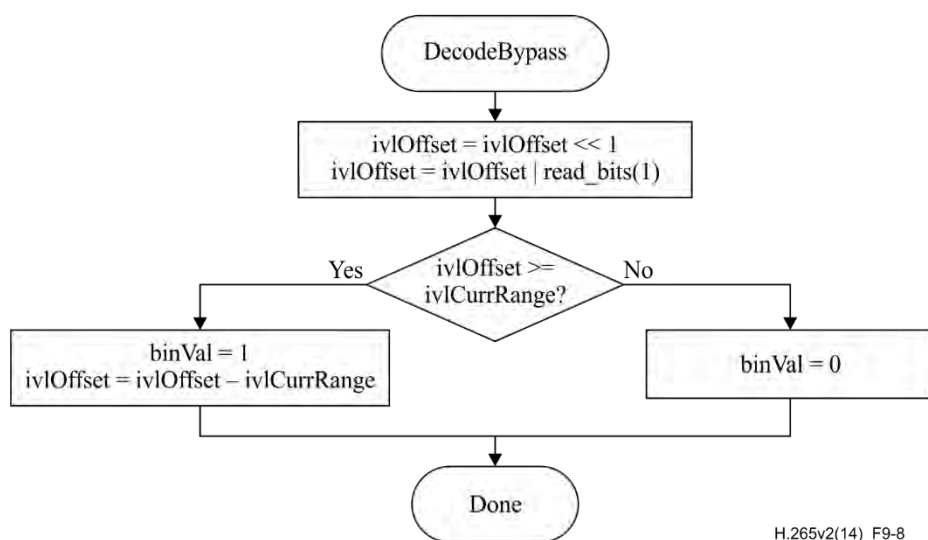

Figure 9-8 – Flowchart of bypass decoding process

9.3.4.3.5 Decoding process for binary decisions before termination

Inputs to this process are bits from slice segment data and the variables `ivlCurrRange` and `ivlOffset`.

Outputs of this process are the updated variables `ivlCurrRange` and `ivlOffset`, and the decoded value `binVal`.

This decoding process applies to decoding of `end_of_slice_segment_flag`, `end_of_subset_one_bit` and `pcm_flag` corresponding to `ctxTable` equal to 0 and `ctxIdx` equal to 0. Figure 9-9 shows the flowchart of the corresponding decoding process, which is specified as follows:

First, the value of `ivlCurrRange` is decremented by 2. Then, the value of `ivlOffset` is compared to the value of `ivlCurrRange` and then the following applies:

- If `ivlOffset` is greater than or equal to `ivlCurrRange`, the variable `binVal` is set equal to 1, no renormalization is carried out, and CABAC decoding is terminated. The last bit inserted in register `ivlOffset` is equal to 1. When decoding `end_of_slice_segment_flag`, this last bit inserted in register `ivlOffset` is interpreted as `rsbp_stop_one_bit`. When decoding `end_of_subset_one_bit`, this last bit inserted in register `ivlOffset` is interpreted as `alignment_bit_equal_to_one`.
- Otherwise (`ivlOffset` is less than `ivlCurrRange`), the variable `binVal` is set equal to 0 and renormalization is performed as specified in clause 9.3.4.3.3.

NOTE – This procedure may also be implemented using `DecodeDecision(ctxTable, ctxIdx, bypassFlag)` with `ctxTable = 0`, `ctxIdx = 0` and `bypassFlag = 0`. In the case where the decoded value is equal to 1, seven more bits would be read by `DecodeDecision(ctxTable, ctxIdx, bypassFlag)` and a decoding process would have to adjust its bitstream pointer accordingly to properly decode following syntax elements.

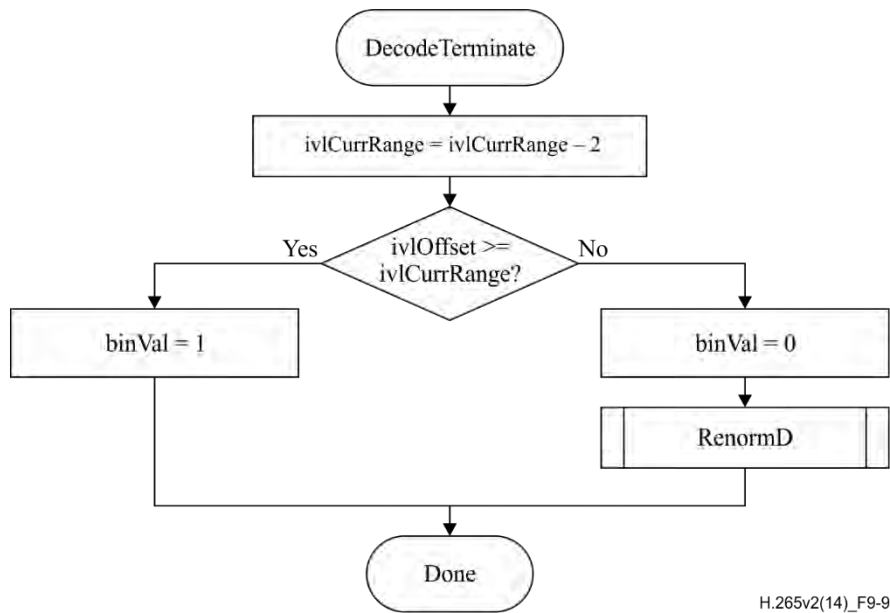

Figure 9-9 – Flowchart of decoding a decision before termination

9.3.4.3.6 Alignment process prior to aligned bypass decoding

Input to this process is the variable `ivlCurrRange`.

Output of this process is the updated variable `ivlCurrRange`.

This process applies prior to the decoding of syntax elements `coeff_abs_level_remaining[]` and `coeff_sign_flag[]`.

`ivlCurrRange` is set equal to 256.

NOTE – When `ivlCurrRange` is 256, `ivlOffset` and the bit-stream can be considered as a shift register, and `binVal` as the register's second most significant bit (the most significant bit is always 0 due to the restriction of `ivlOffset` being less than `ivlCurrRange`).

9.3.5 Arithmetic encoding process (informative)

9.3.5.1 General

This clause does not form an integral part of this Specification.

Inputs to this process are decisions that are to be encoded and written.

Outputs of this process are bits that are written to the RBSP.

This informative clause describes an arithmetic encoding engine that matches the arithmetic decoding engine described in clause 9.3.4.3. The encoding engine is essentially symmetric with the decoding engine, i.e., procedures are called in the same order. The following procedures are described in this clause: `InitEncoder`, `EncodeDecision`, `EncodeBypass`, `EncodeTerminate`, which correspond to `InitDecoder`, `DecodeDecision`, `DecodeBypass` and `DecodeTerminate`, respectively. The state of the arithmetic encoding engine is represented by a value of the variable `ivlLow` pointing to the lower end of a sub-interval and a value of the variable `ivlCurrRange` specifying the corresponding range of that sub-interval.

9.3.5.2 Initialization process for the arithmetic encoding engine (informative)

This clause does not form an integral part of this Specification.

This process is invoked before encoding the first coding block of a slice segment, and after encoding any `pcm_alignment_zero_bit` and all `pcm_sample_luma` and `pcm_sample_chroma` data for a coding unit with `pcm_flag` equal to 1.

Outputs of this process are the values `ivlLow`, `ivlCurrRange`, `firstBitFlag`, `bitsOutstanding` and `BinCountsInNalUnits` of the arithmetic encoding engine.

In the initialization procedure of the encoder, `ivlLow` is set equal to 0 and `ivlCurrRange` is set equal to 510. Furthermore, `firstBitFlag` is set equal to 1 and the counter `bitsOutstanding` is set equal to 0.

Depending on whether the current slice segment is the first slice segment of a coded picture, the following applies:

- If the current slice segment is the first slice segment of a coded picture, the counter `BinCountsInNalUnits` is set equal to 0.
- Otherwise (the current slice segment is not the first slice segment of a coded picture), the counter `BinCountsInNalUnits` is not modified. The value of `BinCountsInNalUnits` is the result of encoding all the slice segments of a coded picture that precede the current slice segment in decoding order. After initializing for the first slice segment of a coded picture as specified in this clause, `BinCountsInNalUnits` is incremented as specified in clauses 9.3.5.3, 9.3.5.5 and 9.3.5.6.

NOTE – The minimum register precision required for storing the values of the variables `ivlLow` and `ivlCurrRange` after invocation of any of the arithmetic encoding processes specified in clauses 9.3.5.3, 9.3.5.5 and 9.3.5.6 is 10 bits and 9 bits, respectively. The encoding process for a binary decision (`EncodeDecision`) as specified in clause 9.3.5.3 and the encoding process for a binary decision before termination (`EncodeTerminate`) as specified in clause 9.3.5.6 require a minimum register precision of 10 bits for the variable `ivlLow` and a minimum register precision of 9 bits for the variable `ivlCurrRange`. The bypass encoding process for binary decisions (`EncodeBypass`) as specified in clause 9.3.5.5 requires a minimum register precision of 11 bits for the variable `ivlLow` and a minimum register precision of 9 bits for the variable `ivlCurrRange`. The precision required for the counters `bitsOutstanding` and `BinCountsInNalUnits` should be sufficiently large to prevent overflow of the related registers. When `maxBinCountInSlice` denotes the maximum total number of binary decisions to encode in one slice segment and `maxBinCountInPic` denotes the maximum total number of binary decisions to encode a picture, the minimum register precision required for the variables `bitsOutstanding` and `BinCountsInNalUnits` is given by $\text{Ceil}(\text{Log2}(\text{maxBinCountInSlice} + 1))$ and $\text{Ceil}(\text{Log2}(\text{maxBinCountInPic} + 1))$, respectively.

9.3.5.3 Encoding process for a binary decision (informative)

This clause does not form an integral part of this Specification.

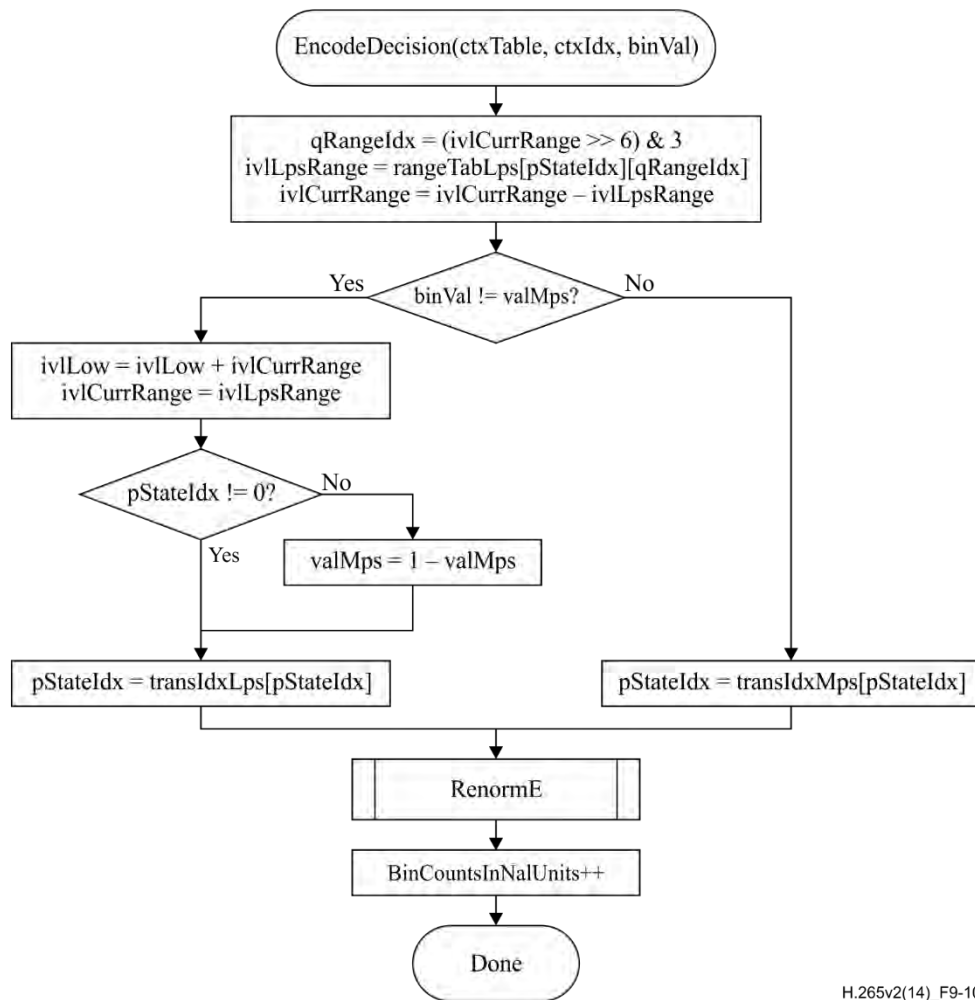

Inputs to this process are the context index `ctxIdx`, the value of `binVal` to be encoded and the variables `ivlCurrRange`, `ivlLow` and `BinCountsInNalUnits`.

Outputs of this process are the variables `ivlCurrRange`, `ivlLow` and `BinCountsInNalUnits`.

Figure 9-10 shows the flowchart for encoding a single decision. In a first step, the variable `ivlLpsRange` is derived as follows:

Given the current value of `ivlCurrRange`, `ivlCurrRange` is mapped to the index `qRangeIdx` of a quantized value of `ivlCurrRange` by using Equation 9-64. The value of `qRangeIdx` and the value of `pStateIdx` associated with `ctxIdx` are used to determine the value of the variable `rangeTabLps` as specified in Table 9-52, which is assigned to `ivlLpsRange`. The value of `ivlCurrRange` – `ivlLpsRange` is assigned to `ivlCurrRange`.

In a second step, the value of `binVal` is compared to `valMps` associated with `ctxIdx`. When `binVal` is different from `valMps`, `ivlCurrRange` is added to `ivlLow` and `ivlCurrRange` is set equal to the value `ivlLpsRange`. Given the encoded decision, the state transition is performed as specified in clause 9.3.4.3.2.2. Depending on the current value of `ivlCurrRange`, renormalization is performed as specified in clause 9.3.5.4. Finally, the variable `BinCountsInNalUnits` is incremented by 1.

H.265v2(14)_F9-10

Figure 9-10 – Flowchart for encoding a decision

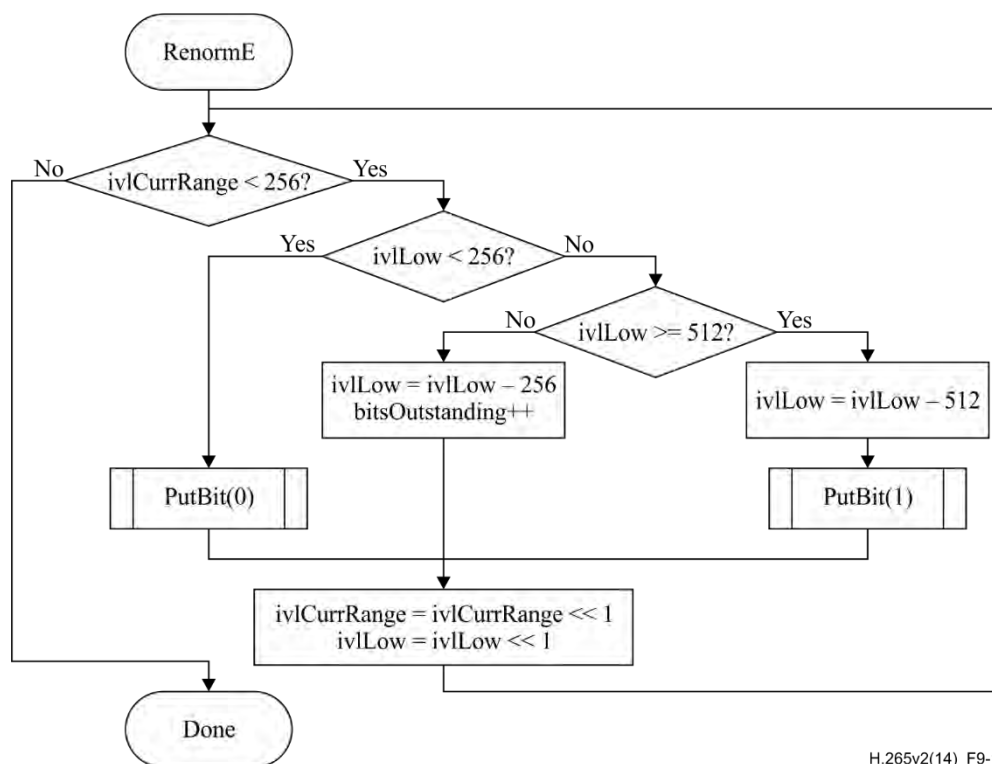

9.3.5.4 Renormalization process in the arithmetic encoding engine (informative)

This clause does not form an integral part of this Specification.

Inputs to this process are the variables ivlCurrRange, ivlLow, firstBitFlag and bitsOutstanding.

Outputs of this process are zero or more bits written to the RBSP and the updated variables ivlCurrRange, ivlLow, firstBitFlag and bitsOutstanding.

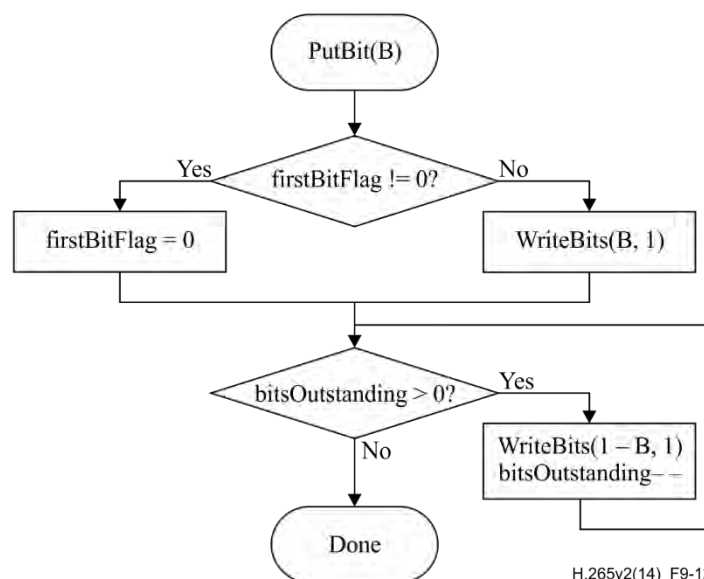

Renormalization in the encoder is illustrated in Figure 9-11.

H.265v2(14)_F9-11

Figure 9-11 – Flowchart of renormalization in the encoder

The PutBit() procedure described in Figure 9-12 provides carry over control. It uses the function WriteBits(B, N) that writes N bits with value B to the bitstream and advances the bitstream pointer by N bit positions. This function assumes the existence of a bitstream pointer with an indication of the position of the next bit to be written to the bitstream by the encoding process.

H.265v2(14)_F9-12

Figure 9-12 – Flowchart of PutBit(B)

9.3.5.5 Bypass encoding process for binary decisions (informative)

This clause does not form an integral part of this Specification.

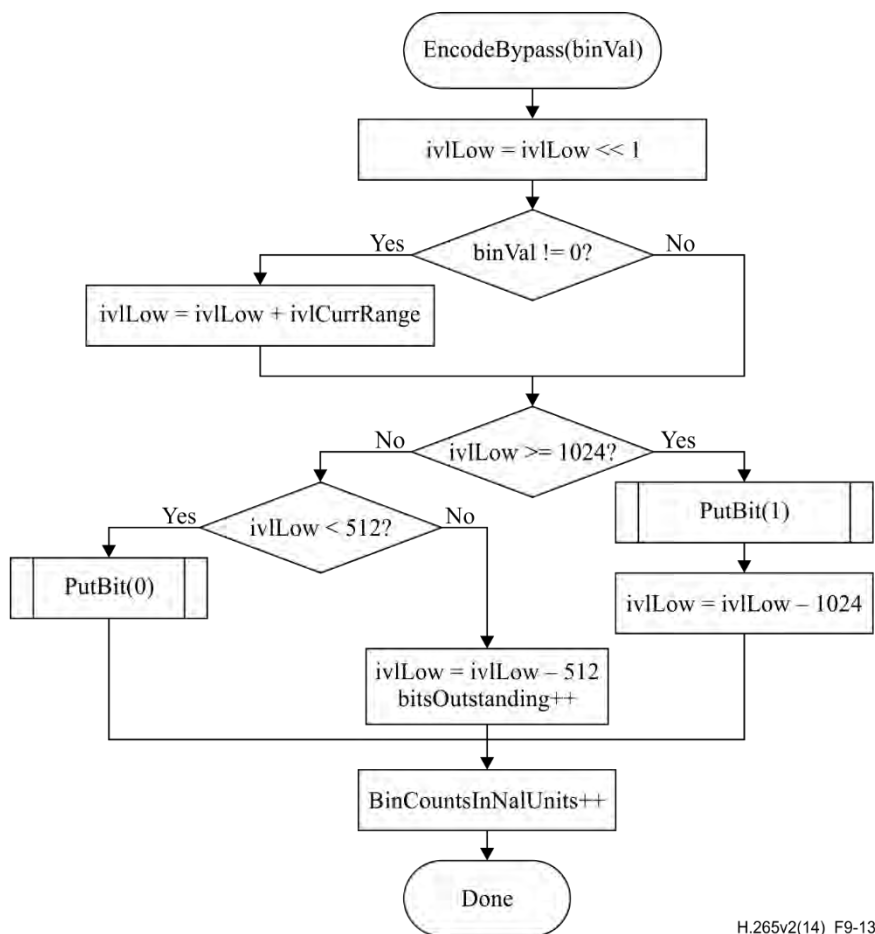

Inputs to this process are the variables binVal, ivlLow, ivlCurrRange, bitsOutstanding and BinCountsInNalUnits.

Output of this process is a bit written to the RBSP and the updated variables `ivlLow`, `bitsOutstanding` and `BinCountsInNalUnits`.

This encoding process applies to all binary decisions with `bypassFlag` equal to 1.

When `cabac_bypass_alignment_enabled_flag` is equal to 1 and `coeff_abs_level_remaining[]` is present for any coefficients in the current sub-block, an alignment process is performed. This alignment process applies prior to the encoding of the syntax elements `coeff_abs_level_remaining[]` and `coeff_sign_flag[]` and sets `ivlCurrRange` to 256.

Renormalization is included in the specification of this bypass encoding process as given in Figure 9-13.

H.265v2(14)_F9-13

Figure 9-13 – Flowchart of encoding bypass

9.3.5.6 Encoding process for a binary decision before termination (informative)

This clause does not form an integral part of this Specification.

Inputs to this process are the variables `binVal`, `ivlCurrRange`, `ivlLow`, `bitsOutstanding` and `BinCountsInNalUnits`.

Outputs of this process are zero or more bits written to the RBSP and the updated variables `ivlLow`, `ivlCurrRange`, `bitsOutstanding` and `BinCountsInNalUnits`.

This encoding routine shown in Figure 9-14 applies to encoding of `end_of_slice_segment_flag`, `end_of_subset_one_bit`, and `pcm_flag`, all associated with `ctxIdx` equal to 0.

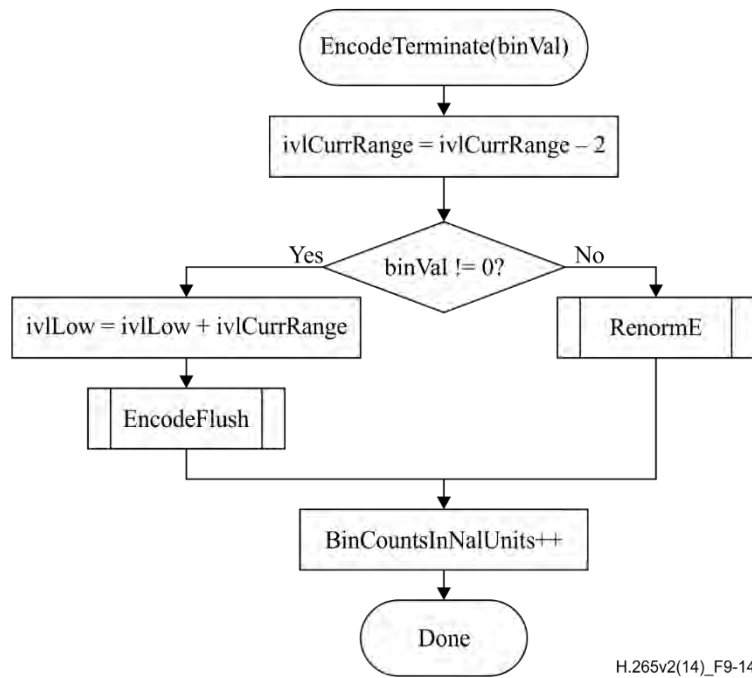

Figure 9-14 – Flowchart of encoding a decision before termination

When the value of binVal to encode is equal to 1, CABAC encoding is terminated and the flushing procedure shown in Figure 9-15 is applied. In this flushing procedure, the last bit written by WriteBits(B, N) is equal to 1. When encoding end_of_slice_segment_flag, this last bit is interpreted as rbsp_stop_one_bit. When encoding end_of_subset_one_bit, this last bit is interpreted as alignment_bit_equal_to_one.

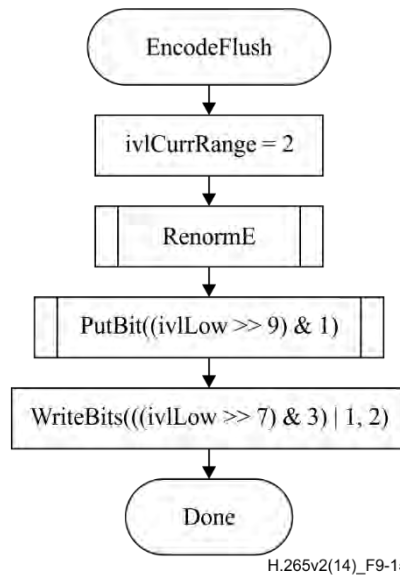

Figure 9-15 – Flowchart of flushing at termination

9.3.5.7 Byte stuffing process (informative)

This clause does not form an integral part of this Specification.

This process is invoked after encoding the last coding block of the last slice segment of a picture and after encapsulation.

Inputs to this process are the number of bytes `NumBytesInVclNalUnits` of all VCL NAL units of a picture, the number of minimum CUs `PicSizeInMinCbsY` in the picture and the number of binary symbols `BinCountsInNalUnits` resulting from encoding the contents of all VCL NAL units of the picture.

NOTE – The value of `BinCountsInNalUnits` is the result of encoding all slice segments of a coded picture. After initializing for the first slice segment of a coded picture as specified in clause 9.3.5.2, `BinCountsInNalUnits` is incremented as specified in clauses 9.3.5.3, 9.3.5.5 and 9.3.5.6.

Outputs of this process are zero or more bytes appended to the NAL unit.

Let the variable `k` be set equal to $\text{Ceil}((\text{Ceil}(3 * (32 * \text{BinCountsInNalUnits} - \text{RawMinCuBits} * \text{PicSizeInMinCbsY}) \div 1024) - \text{NumBytesInVclNalUnits}) \div 3)$. Depending on the value of `k` the following applies:

- If `k` is less than or equal to 0, no `cabac_zero_word` is appended to the NAL unit.
- Otherwise (`k` is greater than 0), the 3-byte sequence `0x000003` is appended `k` times to the NAL unit after encapsulation, where the first two bytes `0x0000` represent a `cabac_zero_word` and the third byte `0x03` represents an `emulation_prevention_three_byte`.

10 Sub-bitstream extraction process

Inputs to this process are a bitstream, a target highest `TemporalId` value `tIdTarget` and a target layer identifier list `layerIdListTarget`.

Output of this process is a sub-bitstream.

It is a requirement of bitstream conformance for the input bitstream that any output sub-bitstream that is the output of the process specified in this clause with the bitstream, `tIdTarget` equal to any value in the range of 0 to 6, inclusive, and `layerIdListTarget` either equal to the layer identifier list associated with a layer set specified in the active VPS or consisting of all the `nuh_layer_id` values of the VCL NAL units present in the input bitstream as inputs, and that satisfies both of the following conditions shall be a conforming bitstream:

- The output sub-bitstream contains at least one VCL NAL unit with `nuh_layer_id` equal to each of the `nuh_layer_id` values in `layerIdListTarget`.
- The output sub-bitstream contains at least one VCL NAL unit with `TemporalId` equal to `tIdTarget`.

NOTE 1 – A bitstream conforming to a profile specified in Annex A contains one or more coded slice segment NAL units with `nuh_layer_id` equal to 0.

NOTE 2 – A conforming bitstream contains one or more coded slice segment NAL units with `TemporalId` equal to 0.

The output sub-bitstream is derived as follows:

- When one or more of the following two conditions are true, remove all SEI NAL units that have `nuh_layer_id` equal to 0 and that contain a non-scalable-nested buffering period SEI message, a non-scalable-nested picture timing SEI message, or a non-scalable-nested decoding unit information SEI message:
 - `layerIdListTarget` does not include all the values of `nuh_layer_id` in all NAL units in the bitstream.
 - `tIdTarget` is less than the greatest `TemporalId` in all NAL units in the bitstream.
- NOTE 3 – A "smart" bitstream extractor may include appropriate non-scalable-nested buffering picture SEI messages, non-scalable-nested picture timing SEI messages and non-scalable-nested decoding unit information SEI messages in the extracted sub-bitstream, provided that the SEI messages applicable to the sub-bitstream were present as scalable-nested SEI messages in the original bitstream.
- Remove all NAL units with `TemporalId` greater than `tIdTarget` or `nuh_layer_id` not among the values included in `layerIdListTarget`.

Annex A

Profiles, tiers and levels

(This annex forms an integral part of this Recommendation | International Standard.)

A.1 Overview of profiles, tiers and levels

Profiles, tiers and levels specify restrictions on the bitstreams and hence limits on the capabilities needed to decode the bitstreams. Profiles, tiers and levels may also be used to indicate interoperability points between individual decoder implementations.

NOTE 1 – This Specification does not include individually selectable "options" at the decoder, as this would increase interoperability difficulties.

Each profile specifies a subset of algorithmic features and limits that shall be supported by all decoders conforming to that profile.

NOTE 2 – Encoders are not required to make use of any particular subset of features supported in a profile.

Each level of a tier specifies a set of limits on the values that may be taken by the syntax elements of this Specification. The same set of tier and level definitions is used with all profiles, but individual implementations may support a different tier and within a tier a different level for each supported profile. For any given profile, a level of a tier generally corresponds to a particular decoder processing load and memory capability.

The profiles that are specified in clause A.3 are also referred to as the profiles specified in Annex A.

A.2 Requirements on video decoder capability

Capabilities of video decoders conforming to this Specification are specified in terms of the ability to decode video streams conforming to the constraints of profiles, tiers and levels specified in this annex and other annexes. When expressing the capabilities of a decoder for a specified profile, the tier and level supported for that profile should also be expressed.

Specific values are specified in this annex and other annexes for the syntax elements `general_profile_idc`, `general_tier_flag`, `general_level_idc`, `sub_layer_profile_idc[i]`, `sub_layer_tier_flag[i]` and `sub_layer_level_idc[i]`. All other values of `general_profile_idc`, `general_level_idc`, `sub_layer_profile_idc[i]` and `sub_layer_level_idc[i]` are reserved for future use by ITU-T | ISO/IEC.

NOTE – Decoders should not infer that a reserved value of `general_profile_idc` or `sub_layer_profile_idc[i]` between the values specified in this Specification indicates intermediate capabilities between the specified profiles, as there are no restrictions on the method to be chosen by ITU-T | ISO/IEC for the use of such future reserved values. However, decoders should infer that a reserved value of `general_level_idc` or `sub_layer_level_idc[i]` associated with a particular value of `general_tier_flag` or `sub_layer_tier_flag[i]`, respectively, between the values specified in this Specification indicates intermediate capabilities between the specified levels of the tier.

A.3 Profiles

A.3.1 General

All constraints for PPSs that are specified are constraints for PPSs that are activated when the bitstream is decoded. All constraints for SPSs that are specified are constraints for SPSs that are activated when the bitstream is decoded.

The variable `RawCtuBits` is derived as follows:

$$\text{RawCtuBits} = \text{CtbSizeY} * \text{CtbSizeY} * \text{BitDepth}_Y + 2 * (\text{CtbWidthC} * \text{CtbHeightC}) * \text{BitDepth}_C \quad (\text{A-1})$$

A.3.2 Main profile

Bitstreams conforming to the Main profile shall obey the following constraints:

- Active VPSs shall have `vps_base_layer_internal_flag` and `vps_base_layer_available_flag` both equal to 1 only.
- Active SPSs for the base layer shall have `chroma_format_idc` equal to 1 only.
- Active SPSs for the base layer shall have `bit_depth_luma_minus8` equal to 0 only.
- Active SPSs for the base layer shall have `bit_depth_chroma_minus8` equal to 0 only.
- Active SPSs for the base layer shall have `transform_skip_rotation_enabled_flag`, `transform_skip_context_enabled_flag`, `implicit_rdpem_enabled_flag`, `explicit_rdpem_enabled_flag`,

extended_precision_processing_flag, intra_smoothing_disabled_flag, high_precision_offsets_enabled_flag, persistent_rice_adaptation_enabled_flag, cabac_bypass_alignment_enabled_flag, sps_curr_pic_ref_enabled_flag, palette_mode_enabled_flag, motion_vector_resolution_control_idc, and intra_boundary_filtering_disabled_flag, when present, equal to 0 only.

- CtbLog2SizeY derived according to active SPSs for the base layer shall be in the range of 4 to 6, inclusive.
- Active PPSs for the base layer shall have log2_max_transform_skip_block_size_minus2, chroma_qp_offset_list_enabled_flag, and residual_adaptive_colour_transform_enabled_flag, when present, equal to 0 only.
- When an active PPS for the base layer has tiles_enabled_flag equal to 1, it shall have entropy_coding_sync_enabled_flag equal to 0.
- When an active PPS for the base layer has tiles_enabled_flag equal to 1, ColumnWidthInLumaSamples[i] shall be greater than or equal to 256 for all values of i in the range of 0 to num_tile_columns_minus1, inclusive, and RowHeightInLumaSamples[j] shall be greater than or equal to 64 for all values of j in the range of 0 to num_tile_rows_minus1, inclusive.
- The number of times read_bits(1) is called in clauses 9.3.4.3.3 and 9.3.4.3.4 when parsing coding_tree_unit() data for any CTU shall be less than or equal to 5 * RawCtuBits / 3.
- general_level_idc and sub_layer_level_idc[i] for all values of i in active SPSs for the base layer shall not be equal to 255 (which indicates level 8.5).
- The tier and level constraints specified for the Main profile in clause A.4 shall be fulfilled.

Conformance of a bitstream to the Main profile is indicated by general_profile_idc being equal to 1 or general_profile_compatibility_flag[1] being equal to 1. Conformance of a sub-layer representation with TemporalId equal to i to the Main profile is indicated by sub_layer_profile_idc[i] being equal to 1 or sub_layer_profile_compatibility_flag[i][1] being equal to 1.

NOTE – When general_profile_compatibility_flag[1] is equal to 1, general_profile_compatibility_flag[2] should also be equal to 1. When sub_layer_profile_compatibility_flag[i][1] is equal to 1 for a value of i, sub_layer_profile_compatibility_flag[i][2] should also be equal to 1.

Decoders conforming to the Main profile at a specific level (identified by a specific value of general_level_idc) of a specific tier (identified by a specific value of general_tier_flag) shall be capable of decoding all bitstreams and sub-layer representations for which all of the following conditions apply:

- The bitstream or sub-layer representation is indicated to conform to the Main profile or the Main Still Picture profile.
- The bitstream or sub-layer representation is indicated to conform to a level that is not level 8.5 and is lower than or equal to the specified level.
- The bitstream or sub-layer representation is indicated to conform to a tier that is lower than or equal to the specified tier.

A.3.3 Main 10 and Main 10 Still Picture profiles

Bitstreams conforming to the Main 10 or Main 10 Still Picture profile shall obey the following constraints:

- In bitstreams conforming to the Main 10 Still Picture profile, the bitstream shall contain only one picture with nuh_layer_id equal to 0.
- Active VPSs shall have vps_base_layer_internal_flag and vps_base_layer_available_flag both equal to 1 only.
- Active SPSs for the base layer shall have chroma_format_idc equal to 1 only.
- Active SPSs for the base layer shall have bit_depth_luma_minus8 in the range of 0 to 2, inclusive.
- Active SPSs for the base layer shall have bit_depth_chroma_minus8 in the range of 0 to 2, inclusive.
- In bitstreams conforming to the Main 10 Still Picture profile, active SPSs for the base layer shall have sps_max_dec_pic_buffering_minus1[sps_max_sub_layers_minus1] equal to 0 only.
- Active SPSs for the base layer shall have transform_skip_rotation_enabled_flag, transform_skip_context_enabled_flag, implicit_rdpem_enabled_flag, explicit_rdpem_enabled_flag, extended_precision_processing_flag, intra_smoothing_disabled_flag, high_precision_offsets_enabled_flag, persistent_rice_adaptation_enabled_flag, cabac_bypass_alignment_enabled_flag, sps_curr_pic_ref_enabled_flag, palette_mode_enabled_flag, motion_vector_resolution_control_idc, and intra_boundary_filtering_disabled_flag, when present, equal to 0 only.

- CtbLog2SizeY derived according to active SPSs for the base layer shall be in the range of 4 to 6, inclusive.
- Active PPSs for the base layer shall have log2_max_transform_skip_block_size_minus2, chroma_qp_offset_list_enabled_flag, and residual_adaptive_colour_transform_enabled_flag, when present, equal to 0 only.
- When an active PPS for the base layer has tiles_enabled_flag equal to 1, it shall have entropy_coding_sync_enabled_flag equal to 0.
- When an active PPS for the base layer has tiles_enabled_flag equal to 1, ColumnWidthInLumaSamples[i] shall be greater than or equal to 256 for all values of i in the range of 0 to num_tile_columns_minus1, inclusive, and RowHeightInLumaSamples[j] shall be greater than or equal to 64 for all values of j in the range of 0 to num_tile_rows_minus1, inclusive.
- The number of times read_bits(1) is called in clauses 9.3.4.3.3 and 9.3.4.3.4 when parsing coding_tree_unit() data for any CTU shall be less than or equal to 5 * RawCtuBits / 3.
- In bitstreams conforming to the Main 10 profile that do not conform to the Main 10 Still Picture profile, general_level_idc and sub_layer_level_idc[i] for all values of i in active SPSs for the base layer shall not be equal to 255 (which indicates level 8.5).
- The tier and level constraints specified for the Main 10 or Main 10 Still Picture profile in clause A.4, as applicable, shall be fulfilled.

Conformance of a bitstream to the Main 10 profile is indicated by general_profile_idc being equal to 2 or general_profile_compatibility_flag[2] being equal to 1. Conformance of a sub-layer representation with TemporalId equal to i to the Main 10 profile is indicated by sub_layer_profile_idc[i] being equal to 2 or sub_layer_profile_compatibility_flag[i][2] being equal to 1.

Conformance of a bitstream to the Main 10 Still Picture profile is indicated by general_one_picture_only_constraint_flag being equal to 1 together with general_profile_idc being equal to 2 or general_profile_compatibility_flag[2] being equal to 1. Conformance of a sub-layer representation with TemporalId equal to i to the Main 10 Still Picture profile is indicated by sub_layer_one_picture_only_constraint_flag being equal to 1 together with sub_layer_profile_idc[i] being equal to 2 or sub_layer_profile_compatibility_flag[i][2] being equal to 1.

NOTE – When the conformance of a bitstream to the Main 10 Still Picture profile is indicated as specified above, and the indicated level is not level 8.5, the conditions for indication of the conformance of the bitstream to the Main 10 profile are also fulfilled.

Decoders conforming to the Main 10 profile at a specific level (identified by a specific value of general_level_idc) of a specific tier (identified by a specific value of general_tier_flag) shall be capable of decoding all bitstreams and sub-layer representations for which all of the following conditions apply:

- The bitstream or sub-layer representation is indicated to conform to the Main 10 profile, the Main profile or the Main Still Picture profile.
- The bitstream or sub-layer representation is indicated to conform to a level that is not level 8.5 and is lower than or equal to the specified level.
- The bitstream or sub-layer representation is indicated to conform to a tier that is lower than or equal to the specified tier.

Decoders conforming to the Main 10 Still Picture profile at a specific level (identified by a specific value of general_level_idc) of a specific tier (identified by a specific value of general_tier_flag) shall be capable of decoding all bitstreams and sub-layer representations for which all of the following conditions apply:

- The bitstream or sub-layer representation is indicated to conform to the Main 10 Still Picture profile or the Main Still Picture profile.
- The bitstream or sub-layer representation is indicated to conform to a level that is not level 8.5 and is lower than or equal to the specified level.
- The bitstream or sub-layer representation is indicated to conform to a tier that is lower than or equal to the specified tier.

A.3.4 Main Still Picture profile

Bitstreams conforming to the Main Still Picture profile shall obey the following constraints:

- The bitstream shall contain only one picture with nuh_layer_id equal to 0.
- Active VPSs shall have vps_base_layer_internal_flag and vps_base_layer_available_flag both equal to 1 only.

- Active SPSs for the base layer shall have `chroma_format_idc` equal to 1 only.
- Active SPSs for the base layer shall have `bit_depth_luma_minus8` equal to 0 only.
- Active SPSs for the base layer shall have `bit_depth_chroma_minus8` equal to 0 only.
- Active SPSs for the base layer shall have `sps_max_dec_pic_buffering_minus1[sps_max_sub_layers_minus1]` equal to 0 only.
- Active SPSs for the base layer shall have `transform_skip_rotation_enabled_flag`, `transform_skip_context_enabled_flag`, `implicit_rdpem_enabled_flag`, `explicit_rdpem_enabled_flag`, `extended_precision_processing_flag`, `intra_smoothing_disabled_flag`, `high_precision_offsets_enabled_flag`, `persistent_rice_adaptation_enabled_flag`, `cabac_bypass_alignment_enabled_flag`, `sps_curr_pic_ref_enabled_flag`, `palette_mode_enabled_flag`, `motion_vector_resolution_control_idc`, and `intra_boundary_filtering_disabled_flag`, when present, equal to 0 only.
- `CtbLog2SizeY` derived according to active SPSs for the base layer shall be in the range of 4 to 6, inclusive.
- Active PPSs for the base layer shall have `log2_max_transform_skip_block_size_minus2`, `chroma_qp_offset_list_enabled_flag`, and `residual_adaptive_colour_transform_enabled_flag`, when present, equal to 0 only.
- When an active PPS for the base layer has `tiles_enabled_flag` equal to 1, it shall have `entropy_coding_sync_enabled_flag` equal to 0.
- When an active PPS for the base layer has `tiles_enabled_flag` equal to 1, `ColumnWidthInLumaSamples[i]` shall be greater than or equal to 256 for all values of `i` in the range of 0 to `num_tile_columns_minus1`, inclusive, and `RowHeightInLumaSamples[j]` shall be greater than or equal to 64 for all values of `j` in the range of 0 to `num_tile_rows_minus1`, inclusive.
- The number of times `read_bits(1)` is called in clauses 9.3.4.3.3 and 9.3.4.3.4 when parsing `coding_tree_unit()` data for any CTU shall be less than or equal to $5 * \text{RawCtuBits} / 3$.
- The tier and level constraints specified for the Main Still Picture profile in clause A.4 shall be fulfilled.

Conformance of a bitstream to the Main Still Picture profile is indicated by `general_profile_idc` being equal to 3 or `general_profile_compatibility_flag[3]` being equal to 1.

NOTE – When `general_profile_compatibility_flag[3]` is equal to 1, `general_profile_compatibility_flag[1]` and `general_profile_compatibility_flag[2]` should also be equal to 1. When `sub_layer_profile_compatibility_flag[i][3]` is equal to 1 for a value of `i`, `sub_layer_profile_compatibility_flag[i][1]` and `sub_layer_profile_compatibility_flag[i][2]` should also be equal to 1.

Decoders conforming to the Main Still Picture profile at a specific level (identified by a specific value of `general_level_idc`) of a specific tier (identified by a specific value of `general_tier_flag`) shall be capable of decoding all bitstreams for which all of the following conditions apply:

- `general_profile_idc` is equal to 3 or `general_profile_compatibility_flag[3]` is equal to 1.
- `general_level_idc` is not equal to 255 and represents a level lower than or equal to the specified level.
- `general_tier_flag` represents a tier lower than or equal to the specified tier.

A.3.5 Format range extensions profiles

The following profiles, collectively referred to as the format range extensions profiles, are specified in this clause:

- The Monochrome, Monochrome 10, Monochrome 12 and Monochrome 16 profiles
- The Main 12 profile
- The Main 4:2:2 10 and Main 4:2:2 12 profiles
- The Main 4:4:4, Main 4:4:4 10 and Main 4:4:4 12 profiles
- The Main Intra, Main 10 Intra, Main 12 Intra, Main 4:2:2 10 Intra, Main 4:2:2 12 Intra, Main 4:4:4 Intra, Main 4:4:4 10 Intra, Main 4:4:4 12 Intra and Main 4:4:4 16 Intra profiles
- The Main 4:4:4 Still Picture and Main 4:4:4 16 Still Picture profiles

Bitstreams conforming to the format range extensions profiles shall obey the following constraints:

- The constraints specified in Table A.1 shall apply, in which entries marked with "–" indicate that the table entry does not impose a profile-specific constraint on the corresponding syntax element.

NOTE – For some syntax elements with table entries marked with "–", a constraint may be imposed indirectly – e.g., by semantics constraints that are imposed elsewhere in this Specification when other specified constraints are fulfilled.

- Active VPSs shall have `vps_base_layer_internal_flag` and `vps_base_layer_available_flag` both equal to 1 only.
- Active SPSs for the base layer shall have `separate_colour_plane_flag`, `cabac_bypass_alignment_enabled_flag`, `sps_curr_pic_ref_enabled_flag`, `palette_mode_enabled_flag`, `motion_vector_resolution_control_idc`, and `intra_boundary_filtering_disabled_flag`, when present, equal to 0 only.
- `CtbLog2SizeY` derived according to active SPSs for the base layer shall be in the range of 4 to 6, inclusive.
- Active PPSs for the base layer shall have `residual_adaptive_colour_transform_enabled_flag`, when present, equal to 0 only.
- When an active PPS for the base layer has `tiles_enabled_flag` equal to 1, it shall have `entropy_coding_sync_enabled_flag` equal to 0.
- When an active PPS for the base layer has `tiles_enabled_flag` equal to 1, `ColumnWidthInLumaSamples[i]` shall be greater than or equal to 256 for all values of `i` in the range of 0 to `num_tile_columns_minus1`, inclusive, and `RowHeightInLumaSamples[j]` shall be greater than or equal to 64 for all values of `j` in the range of 0 to `num_tile_rows_minus1`, inclusive.
- In bitstreams conforming to the Main Intra, Main 10 Intra, Main 12 Intra, Main 4:2:2 10 Intra, Main 4:2:2 12 Intra, Main 4:4:4 Intra, Main 4:4:4 10 Intra, Main 4:4:4 12 Intra or Main 4:4:4 16 Intra profiles, all pictures with `nuh_layer_id` equal to 0 shall be IRAP pictures and the output order indicated in the bitstream among these pictures shall be the same as the decoding order.
- The number of times `read_bits(1)` is called in clauses 9.3.4.3.3 and 9.3.4.3.4 when parsing `coding_tree_unit()` data for any CTU shall be less than or equal to $5 * \text{RawCtuBits} / 3$.
- In bitstreams conforming to the Main 4:4:4 Still Picture and Main 4:4:4 16 Still Picture profiles, the following constraints shall apply:
 - The bitstream shall contain only one picture with `nuh_layer_id` equal to 0.
 - Active SPSs for the base layer shall have `sps_max_dec_pic_buffering_minus1[sps_max_sub_layers_minus1]` equal to 0 only.
- In bitstreams conforming to the Monochrome, Monochrome 10, Monochrome 12, Monochrome 16, Main 12, Main 4:2:2 10, Main 4:2:2 12, Main 4:4:4, Main 4:4:4 10, Main 4:4:4 12, Main Intra, Main 10 Intra, Main 12 Intra, Main 4:2:2 10 Intra, Main 4:2:2 12 Intra, Main 4:4:4 Intra, Main 4:4:4 10 Intra, Main 4:4:4 12 Intra or Main 4:4:4 16 Intra profiles, `general_level_idc` and `sub_layer_level_idc[i]` for all values of `i` in active SPSs for the base layer shall not be equal to 255 (which indicates level 8.5).
- The tier and level constraints specified for the Monochrome, Monochrome 10, Monochrome 12, Monochrome 16, Main 12, Main 4:2:2 10, Main 4:2:2 12, Main 4:4:4 10, Main 4:4:4 12, Main Intra, Main 10 Intra, Main 12 Intra, Main 4:2:2 10 Intra, Main 4:2:2 12 Intra, Main 4:4:4 10 Intra, Main 4:4:4 12 Intra or Main 4:4:4 16 Intra profiles in clause A.4, as applicable, shall be fulfilled.

Table A.1 – Allowed values for syntax elements in the format range extensions profiles

Profile for which constraint is specified	chroma_format_idc	bit_depth_luma_minus8 and bit_depth_chroma_minus8	transform_skip_rotation_enabled_flag, transform_skip_context_enabled_flag, implicit_rdpem_enabled_flag, explicit_rdpem_enabled_flag, intra_smoothing_disabled_flag, persistent_rice_adaptation_enabled_flag and log2_max_transform_skip_block_size_minus2	extended_precision_processing_flag	chroma_qp_offset_list_enabled_flag
Monochrome	0	0	0	0	0
Monochrome 10	0	0..2	0	0	0
Monochrome 12	0	0..4	0	0	0
Monochrome 16	0	–	–	–	0
Main 12	0 or 1	0..4	0	0	0
Main 4:2:2 10	0..2	0..2	0	0	–
Main 4:2:2 12	0..2	0..4	0	0	–
Main 4:4:4	–	0	–	0	–
Main 4:4:4 10	–	0..2	–	0	–
Main 4:4:4 12	–	0..4	–	0	–
Main Intra	0 or 1	0	0	0	0
Main 10 Intra	0 or 1	0..2	0	0	0
Main 12 Intra	0 or 1	0..4	0	0	0
Main 4:2:2 10 Intra	0..2	0..2	0	0	–
Main 4:2:2 12 Intra	0..2	0..4	0	0	–
Main 4:4:4 Intra	–	0	–	0	–
Main 4:4:4 10 Intra	–	0..2	–	0	–
Main 4:4:4 12 Intra	–	0..4	–	0	–
Main 4:4:4 16 Intra	–	–	–	–	–
Main 4:4:4 Still Picture	–	0	–	0	–
Main 4:4:4 16 Still Picture	–	–	–	–	–

Conformance of a bitstream to the format range extensions profiles is indicated by `general_profile_idc` being equal to 4 or `general_profile_compatibility_flag[4]` being equal to 1 with the additional indications specified in Table A.2. Conformance of a sub-layer representation with `TemporalId` equal to `i` to the format range extensions profiles is indicated by `sub_layer_profile_idc[i]` being equal to 4 or `sub_layer_profile_compatibility_flag[i][4]` being equal to 1 with the additional indications specified in Table A.2, with each of the syntax elements in Table A.2 being replaced by its `i`-th corresponding sub-layer syntax element.

All other combinations of the syntax elements in Table A.2 with `general_profile_idc` equal to 4 or `general_profile_compatibility_flag[4]` equal to 1 are reserved for future use by ITU-T | ISO/IEC. All other combinations of the *i*-th corresponding sub-layer syntax elements of the syntax elements in Table A.2 with `sub_layer_profile_idc[i]` equal to 4 or `sub_layer_profile_compatibility_flag[i][4]` equal to 1 are reserved for future use by ITU-T | ISO/IEC. Such combinations shall not be present in bitstreams conforming to this Specification. However, decoders conforming to the format range extensions profiles shall allow other combinations as specified below in this clause to occur in the bitstream.

Table A.2 – Bitstream indications for conformance to format range extensions profiles

Profile for which the bitstream indicates conformance	<code>general_max_12bit_constraint_flag</code>	<code>general_max_10bit_constraint_flag</code>	<code>general_max_8bit_constraint_flag</code>	<code>general_max_422chroma_constraint_flag</code>	<code>general_max_420chroma_constraint_flag</code>	<code>general_max_monochrome_constraint_flag</code>	<code>general_intra_constraint_flag</code>	<code>general_one_picture_only_constraint_flag</code>	<code>general_lower_bit_rate_constraint_flag</code>
Monochrome	1	1	1	1	1	1	0	0	1
Monochrome 10	1	1	0	1	1	1	0	0	1
Monochrome 12	1	0	0	1	1	1	0	0	1
Monochrome 16	0	0	0	1	1	1	0	0	1
Main 12	1	0	0	1	1	0	0	0	1
Main 4:2:2 10	1	1	0	1	0	0	0	0	1
Main 4:2:2 12	1	0	0	1	0	0	0	0	1
Main 4:4:4	1	1	1	0	0	0	0	0	1
Main 4:4:4 10	1	1	0	0	0	0	0	0	1
Main 4:4:4 12	1	0	0	0	0	0	0	0	1
Main Intra	1	1	1	1	1	0	1	0	0 or 1
Main 10 Intra	1	1	0	1	1	0	1	0	0 or 1
Main 12 Intra	1	0	0	1	1	0	1	0	0 or 1
Main 4:2:2 10 Intra	1	1	0	1	0	0	1	0	0 or 1
Main 4:2:2 12 Intra	1	0	0	1	0	0	1	0	0 or 1
Main 4:4:4 Intra	1	1	1	0	0	0	1	0	0 or 1
Main 4:4:4 10 Intra	1	1	0	0	0	0	1	0	0 or 1
Main 4:4:4 12 Intra	1	0	0	0	0	0	1	0	0 or 1
Main 4:4:4 16 Intra	0	0	0	0	0	0	1	0	0 or 1
Main 4:4:4 Still Picture	1	1	1	0	0	0	1	1	0 or 1
Main 4:4:4 16 Still Picture	0	0	0	0	0	0	1	1	0 or 1

Decoders conforming to a format range extensions profile at a specific level (identified by a specific value of `general_level_idc`) of a specific tier (identified by a specific value of `general_tier_flag`) shall be capable of decoding all bitstreams and sub-layer representations for which all of the following conditions apply:

- Any of the following conditions apply:
 - The decoder conforms to the Main 12, Main 4:2:2 10, Main 4:2:2 12, Main 4:4:4, Main 4:4:4 10 or Main 4:4:4 12 profile, and the bitstream or sub-layer representation is indicated to conform to the Main profile or the Main Still Picture profile.
 - The decoder conforms to the Main 12, Main 4:2:2 10, Main 4:2:2 12, Main 4:4:4 10 or Main 4:4:4 12 profile, and the bitstream or sub-layer representation is indicated to conform to the Main 10 profile, the Main profile or the Main Still Picture profile.
 - The decoder conforms to the Main Intra, Main 10 Intra, Main 12 Intra, Main 4:2:2 10 Intra, Main 4:2:2 12 Intra, Main 4:4:4 Intra, Main 4:4:4 10 Intra, or Main 4:4:4 12 Intra, Main 4:4:4 16 Intra, Main 4:4:4 Still Picture, or Main 4:4:4 16 Still Picture profile, and the bitstream or sub-layer representation is indicated to conform to the Main Still Picture profile.
 - `general_profile_idc` is equal to 4 or `general_profile_compatibility_flag[4]` is equal to 1 for the bitstream, and the value of each constraint flag listed in Table A.2 is greater than or equal to the value(s) specified in the row of Table A.2 for the format range extensions profile for which the decoder conformance is evaluated.
 - `sub_layer_profile_idc[i]` is equal to 4 or `sub_layer_profile_compatibility_flag[i][4]` is equal to 1 for the sub-layer representation, and the value of each constraint flag listed in Table A.2 is greater than or equal to the value(s) specified in the row of Table A.2 for the format range extensions profile for which the decoder conformance is evaluated, with each of the syntax elements in Table A.2 being replaced by its *i*-th corresponding sub-layer syntax element.
- The bitstream or sub-layer representation is indicated to conform to a level that is not level 8.5 and is lower than or equal to the specified level.
- The bitstream or sub-layer representation is indicated to conform to a tier that is lower than or equal to the specified tier.

For decoders conforming to the Main Intra, Main 10 Intra, Main 12 Intra, Main 4:2:2 10 Intra, Main 4:2:2 12 Intra, Main 4:4:4 Intra, Main 4:4:4 10 Intra, Main 4:4:4 12 Intra, Main 4:4:4 16 Intra, Main 4:4:4 Still Picture, or Main 4:4:4 16 Still picture profile, the application of either or both of the in-loop filters of the in-loop filter process specified in clause 8.7 is optional.

A.3.6 High throughput profiles

The following profiles, collectively referred to as the high throughput profiles, are specified in this clause:

- The High Throughput 4:4:4, High Throughput 4:4:4 10 and High Throughput 4:4:4 14 profiles
- The High Throughput 4:4:4 16 Intra profile

NOTE 1 – For purposes of this terminology, the high-throughput screen content coding extensions profiles specified in clause A.3.8 are not included in the set of profiles that are collectively referred to as the high throughput profiles, although the names of some of the high-throughput screen content coding extensions profiles include the term "High Throughput".

Bitstreams conforming to the high throughput profiles shall obey the following constraints:

- Active VPSs shall have `vps_base_layer_internal_flag` and `vps_base_layer_available_flag` both equal to 1 only.
- Active SPSs for the base layer shall have `separate_colour_plane_flag`, `sps_curr_pic_ref_enabled_flag`, `palette_mode_enabled_flag`, `motion_vector_resolution_control_idc`, and `intra_boundary_filtering_disabled_flag`, when present, equal to 0 only.
- In bitstreams conforming to the High Throughput 4:4:4 profile, active SPSs for the base layer shall have `bit_depth_luma_minus8` equal to 0, `bit_depth_chroma_minus8` equal to 0, `extended_precision_processing_flag` equal to 0, and `cabac_bypass_alignment_enabled_flag` equal to 0 only.
- In bitstreams conforming to the High Throughput 4:4:4 10 profile, active SPSs for the base layer shall have `bit_depth_luma_minus8` less than or equal to 2, `bit_depth_chroma_minus8` less than or equal to 2, `extended_precision_processing_flag` equal to 0, and `cabac_bypass_alignment_enabled_flag` equal to 0 only.
- In bitstreams conforming to the High Throughput 4:4:4 14 profile, active SPSs for the base layer shall have `bit_depth_luma_minus8` less than or equal to 6 and `bit_depth_chroma_minus8` less than or equal to 6.

- In bitstreams conforming to the High Throughput 4:4:4 16 Intra profile, active SPSs for the base layer shall have `cabac_bypass_alignment_enabled_flag` equal to 1 only.
- `CtbLog2SizeY` derived according to active SPSs for the base layer shall be in the range of 4 to 6, inclusive.
- Active PPSs for the base layer shall have `residual_adaptive_colour_transform_enabled_flag`, when present, equal to 0 only.
- In bitstreams conforming to the High Throughput 4:4:4, High Throughput 4:4:4 10, or High Throughput 4:4:4 14 profiles, active PPSs for the base layer shall have `entropy_coding_sync_enabled_flag` equal to 1 only.
 NOTE 2 – Unlike for some other profiles specified in this annex, an active PPS for the base layer for the high throughput profiles may have `tiles_enabled_flag` equal to 1 with `entropy_coding_sync_enabled_flag` equal to 1.
- When an active PPS for the base layer has `tiles_enabled_flag` equal to 1, `ColumnWidthInLumaSamples[i]` shall be greater than or equal to 256 for all values of `i` in the range of 0 to `num_tile_columns_minus1`, inclusive, and `RowHeightInLumaSamples[j]` shall be greater than or equal to 64 for all values of `j` in the range of 0 to `num_tile_rows_minus1`, inclusive.
- In bitstreams conforming to the High Throughput 4:4:4 16 Intra profile, all pictures with `nuh_layer_id` equal to 0 shall be IRAP pictures and the output order indicated in the bitstream among these pictures shall be the same as the decoding order.
- The number of times `read_bits(1)` is called in clauses 9.3.4.3.3 and 9.3.4.3.4 when parsing `coding_tree_unit()` data for any CTU shall be less than or equal to $5 * \text{RawCtuBits} / 3$.
- `general_level_idc` and `sub_layer_level_idc[i]` for all values of `i` in active SPSs for the base layer shall not be equal to 255 (which indicates level 8.5).
- The tier and level constraints specified for the High Throughput 4:4:4, High Throughput 4:4:4 10, High Throughput 4:4:4 14 or High Throughput 4:4:4 16 Intra profile in clause A.4, as applicable, shall be fulfilled.

Conformance of a bitstream to the high throughput profiles is indicated by `general_profile_idc` being equal to 5 or `general_profile_compatibility_flag[5]` being equal to 1 with the additional indications specified in Table A.3. Conformance of a sub-layer representation with `TemporalId` equal to `i` to the high throughput profiles is indicated by `sub_layer_profile_idc[i]` being equal to 5 or `sub_layer_profile_compatibility_flag[i][5]` being equal to 1 with the additional indications specified in Table A.3, with each of the syntax elements in Table A.3 being replaced by its `i`-th corresponding sub-layer syntax element.

All other combinations of the syntax elements in Table A.3 with `general_profile_idc` equal to 5 or `general_profile_compatibility_flag[5]` equal to 1 are reserved for future use by ITU-T | ISO/IEC. All other combinations of the `i`-th corresponding sub-layer syntax elements of the syntax elements in Table A.3 with `sub_layer_profile_idc[i]` equal to 5 or `sub_layer_profile_compatibility_flag[i][5]` equal to 1 are reserved for future use by ITU-T | ISO/IEC. Such combinations shall not be present in bitstreams conforming to this Specification. However, decoders conforming to the format range extensions profiles shall allow other combinations as specified below in this clause to occur in the bitstream.

Table A.3 – Bitstream indications for conformance to high throughput profiles

Profile for which the bitstream indicates conformance	general_lower_bit_rate_constraint_flag	general_one_picture_only_constraint_flag	general_intra_constraint_flag	general_max_monochrome_constraint_flag	general_max_420chroma_constraint_flag	general_max_422chroma_constraint_flag	general_max_8bit_constraint_flag	general_max_10bit_constraint_flag	general_max_12bit_constraint_flag	general_max_14bit_constraint_flag
High Throughput 4:4:4	1	1	1	1	0	0	0	0	0	1
High Throughput 4:4:4 10	1	1	1	0	0	0	0	0	0	1
High Throughput 4:4:4 14	1	0	0	0	0	0	0	0	0	1
High Throughput 4:4:4 16 Intra	0	0	0	0	0	0	0	0	1	0 or 1

Decoders conforming to a high throughput profile at a specific level (identified by a specific value of `general_level_idc`) of a specific tier (identified by a specific value of `general_tier_flag`) shall be capable of decoding all bitstreams or sub-layer representations for which all of the following conditions apply:

- Any of the following conditions apply:
 - `general_profile_idc` is equal to 5 or `general_profile_compatibility_flag[5]` is equal to 1 for the bitstream and the value of each constraint flag listed in Table A.3 is greater than or equal to the value(s) specified in the row of Table A.3 for the high throughput profile for which the decoder conformance is evaluated.
 - `sub_layer_profile_idc[i]` is equal to 5 or `sub_layer_profile_compatibility_flag[i][5]` is equal to 1 for the sub-layer representation, and the value of each constraint flag listed in Table A.3 is greater than or equal to the value(s) specified in the row of Table A.3 for the high throughput profile for which the decoder conformance is evaluated, with each of the syntax elements in Table A.3 being replaced by its *i*-th corresponding sub-layer syntax element.
- The bitstream or sub-layer representation is indicated to conform to a level that is not level 8.5 and is lower than or equal to the specified level.
- The bitstream or sub-layer representation is indicated to conform to a tier that is lower than or equal to the specified tier.

For decoders conforming to the High Throughput 4:4:4 16 Intra profile, the application of either or both of the in-loop filters of the in-loop filter process specified in clause 8.7 is optional.

A.3.7 Screen content coding extensions profiles

The following profiles, collectively referred to as the screen content coding extensions profiles, are specified in this clause:

- The Screen-Extended Main and Screen-Extended Main 10 profiles
- The Screen-Extended Main 4:4:4 and Screen-Extended Main 4:4:4 10 profiles

NOTE – For purposes of this terminology, the high throughput screen content coding extensions profiles specified in clause A.3.8 are not included in the set of profiles that are collectively referred to as the screen content coding extensions profiles, although the names of some of the high throughput screen content coding extensions profiles include the term "Screen-Extended".

Bitstreams conforming to the screen content coding extensions profiles shall obey the following constraints:

- The constraints specified in Table A.4 shall apply, in which entries marked with "-" indicate that the table entry does not impose a profile-specific constraint on the corresponding syntax element.

- Active VPSs shall have `vps_base_layer_internal_flag` and `vps_base_layer_available_flag` both equal to 1 only.
- Active SPSs for the base layer shall have `separate_colour_plane_flag`, when present, equal to 0 only.
- `CtbLog2SizeY` derived according to active SPSs for the base layer shall be in the range of 4 to 6, inclusive.
- When an active SPS for the base layer has `palette_mode_enabled_flag` equal to 1, `palette_max_size` shall be less than or equal to 64 and `PaletteMaxPredictorSize` shall be less than or equal to 128.
- In bitstreams conforming to the Screen-Extended Main, Screen-Extended Main 10, Screen-Extended Main 4:4:4, or Screen-Extended Main 4:4:4 10 profiles, active SPSs for the base layer shall have `extended_precision_processing_flag`, and `cabac_bypass_alignment_enabled_flag`, when present, equal to 0 only.
- In bitstreams conforming to the Screen-Extended Main or Screen-Extended Main 10 profiles, when an active PPS for the base layer has `tiles_enabled_flag` equal to 1, it shall have `entropy_coding_sync_enabled_flag` equal to 0.
- When an active PPS for the base layer has `tiles_enabled_flag` equal to 1, `ColumnWidthInLumaSamples[i]` shall be greater than or equal to 256 for all values of `i` in the range of 0 to `num_tile_columns_minus1`, inclusive, and `RowHeightInLumaSamples[j]` shall be greater than or equal to 64 for all values of `j` in the range of 0 to `num_tile_rows_minus1`, inclusive.
- The number of times `read_bits(1)` is called in clauses 9.3.4.3.3 and 9.3.4.3.4 when parsing `coding_tree_unit()` data for any CTU shall be less than or equal to $5 * \text{RawCtuBits} / 3$.
- `general_level_idc` and `sub_layer_level_idc[i]` for all values of `i` in active SPSs for the base layer shall not be equal to 255 (which indicates level 8.5).
- The tier and level constraints specified for the Screen-Extended Main, Screen-Extended Main 10, Screen-Extended Main 4:4:4 or Screen-Extended Main 4:4:4 10 profiles in clause A.4, as applicable, shall be fulfilled.

Table A.4 – Allowed values for syntax elements in the screen content coding extensions profiles

Profile for which constraint is specified	<code>chroma_format_idc</code>	<code>bit_depth_luma_minus8</code> and <code>bit_depth_chroma_minus8</code>
Screen-Extended Main	1	0
Screen-Extended Main 10	1	0..2
Screen-Extended Main 4:4:4	0, 1, or 3	0
Screen-Extended Main 4:4:4 10	0, 1, or 3	0..2

Conformance of a bitstream to the screen content coding extensions profiles is indicated by `general_profile_idc` being equal to 9 or `general_profile_compatibility_flag[9]` being equal to 1 with the additional indications specified in Table A.5. Conformance of a sub-layer representation with `TemporalId` equal to `i` to the screen content coding extensions profiles is indicated by `sub_layer_profile_idc[i]` being equal to 9 or `sub_layer_profile_compatibility_flag[i][9]` being equal to 1 with the additional indications specified in Table A.5, with each of the syntax elements in Table A.5 being replaced by its `i`-th corresponding sub-layer syntax element.

All other combinations of the syntax elements in Table A.5 with `general_profile_idc` equal to 9 or `general_profile_compatibility_flag[9]` equal to 1 are reserved for future use by ITU-T | ISO/IEC. All other combinations of the *i*-th corresponding sub-layer syntax elements of the syntax elements in Table A.5 with `sub_layer_profile_idc[i]` equal to 9 or `sub_layer_profile_compatibility_flag[i][9]` equal to 1 are reserved for future use by ITU-T | ISO/IEC. Such combinations shall not be present in bitstreams conforming to this Specification. However, decoders conforming to the screen content coding extensions profiles shall allow other combinations as specified below in this clause to occur in the bitstream.

Table A.5 – Bitstream indications for conformance to screen content coding extensions profiles

Profile for which the bitstream indicates conformance	<code>general_max_14bit_constraint_flag</code>	<code>general_max_12bit_constraint_flag</code>	<code>general_max_10bit_constraint_flag</code>	<code>general_max_8bit_constraint_flag</code>	<code>general_max_422chroma_constraint_flag</code>	<code>general_max_420chroma_constraint_flag</code>	<code>general_max_monochrome_constraint_flag</code>	<code>general_intra_constraint_flag</code>	<code>general_one_picture_only_constraint_flag</code>	<code>general_lower_bit_rate_constraint_flag</code>
Screen-Extended Main	1	1	1	1	1	1	0	0	0	1
Screen-Extended Main 10	1	1	1	0	1	1	0	0	0	1
Screen-Extended Main 4:4:4	1	1	1	1	0	0	0	0	0	1
Screen-Extended Main 4:4:4 10	1	1	1	0	0	0	0	0	0	1

Decoders conforming to a screen content coding extensions profile at a specific level (identified by a specific value of `general_level_idc`) of a specific tier (identified by a specific value of `general_tier_flag`) shall be capable of decoding all bitstreams and sub-layer representations for which all of the following conditions apply:

- Any of the following conditions apply:
 - The bitstream or sub-layer representation is indicated to conform to the Main, Main Still Picture, or Monochrome profile.
 - The decoder conforms to the Screen-Extended Main 10 or Screen-Extended Main 4:4:4 10 profile, and the bitstream or sub-layer representation is indicated to conform to the Main 10 profile.
 - The decoder conforms to the Screen-Extended Main 4:4:4 or Screen-Extended Main 4:4:4 10 profile, and the bitstream or sub-layer representation is indicated to conform to the Main 4:4:4 profile.
 - The decoder conforms to the Screen-Extended Main 4:4:4 10 profile, and the bitstream or sub-layer representation is indicated to conform to the Main 4:4:4 10 profile.
 - `general_profile_idc` is equal to 4 or `general_profile_compatibility_flag[4]` is equal to 1 or `general_profile_idc` is equal to 9 or `general_profile_compatibility_flag[9]` is equal to 1 for the bitstream, and the value of each constraint flag listed in Table A.5 is greater than or equal to the value(s) specified in the row of Table A.5 for the screen content coding extensions profile for which the decoder conformance is evaluated, and `general_max_422chroma_constraint_flag` is equal to `general_max_420chroma_constraint_flag`.
 - `sub_layer_profile_idc[i]` is equal to 4 or `sub_layer_profile_compatibility_flag[i][4]` is equal to 1 or `sub_layer_profile_idc[i]` is equal to 9 or `sub_layer_profile_compatibility_flag[i][9]` is equal to 1 for the sub-layer representation, and the value of each constraint flag listed in Table A.5 is greater than or equal to the value(s) specified in the row of Table A.5 for the screen content coding extensions profile for which the decoder conformance is evaluated, and `general_max_422chroma_constraint_flag` is equal to `general_max_420chroma_constraint_flag`, with each of the syntax elements in Table A.5 being replaced by its *i*-th corresponding sub-layer syntax element.

- The bitstream or sub-layer representation is indicated to conform to a level that is not level 8.5 and is lower than or equal to the specified level.
- The bitstream or sub-layer representation is indicated to conform to a tier that is lower than or equal to the specified tier.

A.3.8 High throughput screen content coding extensions profiles

The following profiles, collectively referred to as the high throughput screen content coding extensions profiles, are specified in this clause:

- The Screen-Extended High Throughput 4:4:4, Screen-Extended High Throughput 4:4:4 10, and Screen-Extended High Throughput 14 profiles

Bitstreams conforming to the screen content coding extensions profiles shall obey the following constraints:

- The constraints specified in Table A.6 shall apply, in which entries marked with "-" indicate that the table entry does not impose a profile-specific constraint on the corresponding syntax element.
- Active VPSs shall have `vps_base_layer_internal_flag` and `vps_base_layer_available_flag` both equal to 1 only.
- Active SPSs for the base layer shall have `separate_colour_plane_flag`, when present, equal to 0 only.
- `CtbLog2SizeY` derived according to active SPSs for the base layer shall be in the range of 4 to 6, inclusive.
- When an active SPS for the base layer has `palette_mode_enabled_flag` equal to 1, `palette_max_size` shall be less than or equal to 64 and `PaletteMaxPredictorSize` shall be less than or equal to 128.
- Active SPSs for the base layer shall have `extended_precision_processing_flag`, and `cabac_bypass_alignment_enabled_flag`, when present, equal to 0 only.
- Active PPSs for the base layer shall have `entropy_coding_sync_enabled_flag` equal to 1 only.
NOTE – Unlike for some other profiles specified in this annex, an active PPS for the base layer for Screen-Extended High Throughput 4:4:4, Screen-Extended High Throughput 4:4:4 10, or Screen-Extended High Throughput 4:4:4 14 profiles may have `tiles_enabled_flag` equal to 1 with `entropy_coding_sync_enabled_flag` equal to 1.
- When an active PPS for the base layer has `tiles_enabled_flag` equal to 1, `ColumnWidthInLumaSamples[i]` shall be greater than or equal to 256 for all values of `i` in the range of 0 to `num_tile_columns_minus1`, inclusive, and `RowHeightInLumaSamples[j]` shall be greater than or equal to 64 for all values of `j` in the range of 0 to `num_tile_rows_minus1`, inclusive.
- The number of times `read_bits(1)` is called in clauses 9.3.4.3.3 and 9.3.4.3.4 when parsing `coding_tree_unit()` data for any CTU shall be less than or equal to $5 * \text{RawCtuBits} / 3$.
- `general_level_idc` and `sub_layer_level_idc[i]` for all values of `i` in active SPSs for the base layer shall not be equal to 255 (which indicates level 8.5).
- The tier and level constraints specified for the Screen-Extended High Throughput 4:4:4, Screen-Extended High Throughput 4:4:4 10, and Screen-Extended High Throughput 14 profiles in clause A.4, as applicable, shall be fulfilled.

Table A.6 – Allowed values for syntax elements in the high throughput screen content coding extensions profiles

Profile for which constraint is specified	chroma_format_idc	bit_depth_luma_minus8 and bit_depth_chroma_minus8
Screen-Extended High Throughput 4:4:4	–	0
Screen-Extended High Throughput 4:4:4 10	–	0..2
Screen-Extended High Throughput 4:4:4 14	–	0..6

Conformance of a bitstream to the high throughput screen content coding extensions profiles is indicated by `general_profile_idc` being equal to 11 or `general_profile_compatibility_flag[11]` being equal to 1 with the additional indications specified in Table A.7. Conformance of a sub-layer representation with `TemporalId` equal to `i` to the screen content coding extensions profiles is indicated by `sub_layer_profile_idc[i]` being equal to 11 or `sub_layer_profile_compatibility_flag[i][11]` being equal to 1 with the additional indications specified in Table A.7, with each of the syntax elements in Table A.7 being replaced by its `i`-th corresponding sub-layer syntax element.

All other combinations of the syntax elements in Table A.7 with `general_profile_idc` equal to 11 or `general_profile_compatibility_flag[11]` equal to 1 are reserved for future use by ITU-T | ISO/IEC. All other combinations of the `i`-th corresponding sub-layer syntax elements of the syntax elements in Table A.7 with `sub_layer_profile_idc[i]` equal to 11 or `sub_layer_profile_compatibility_flag[i][11]` equal to 1 are reserved for future use by ITU-T | ISO/IEC. Such combinations shall not be present in bitstreams conforming to this Specification. However, decoders conforming to the screen content coding extensions profiles shall allow other combinations as specified below in this clause to occur in the bitstream.

Table A.7 – Bitstream indications for conformance to high throughput screen content coding extensions profiles

Profile for which the bitstream indicates conformance	general_max_14bit_constraint_flag	general_max_12bit_constraint_flag	general_max_10bit_constraint_flag	general_max_8bit_constraint_flag	general_max_422chroma_constraint_flag	general_max_420chroma_constraint_flag	general_max_monochrome_constraint_flag	general_intra_constraint_flag	general_one_picture_only_constraint_flag	general_lower_bit_rate_constraint_flag
Screen-Extended High Throughput 4:4:4	1	1	1	1	0	0	0	0	0	1
Screen-Extended High Throughput 4:4:4 10	1	1	1	0	0	0	0	0	0	1
Screen-Extended High Throughput 4:4:4 14	1	0	0	0	0	0	0	0	0	1

Decoders conforming to a high throughput screen content coding extensions profile at a specific level (identified by a specific value of `general_level_idc`) of a specific tier (identified by a specific value of `general_tier_flag`) shall be capable of decoding all bitstreams and sub-layer representations for which all of the following conditions apply:

- Any of the following conditions apply:
 - The bitstream or sub-layer representation is indicated to conform to the Main, Main Still Picture, or Monochrome profile.
 - The bitstream or sub-layer representation is indicated to conform to the High Throughput 4:4:4 profile.
 - The decoder conforms to the Screen-Extended High Throughput 4:4:4 10 or Screen-Extended High Throughput 4:4:4 14 profile, and the bitstream or sub-layer representation is indicated to conform to the High Throughput 4:4:4 10 profile.
 - The decoder conforms to the Screen-Extended High Throughput 4:4:4 14 profile, and the bitstream or sub-layer representation is indicated to conform to the High Throughput 4:4:4 14 profile.
 - `general_profile_idc` is equal to 4 or `general_profile_compatibility_flag[4]` is equal to 1 or `general_profile_idc` is equal to 11 or `general_profile_compatibility_flag[11]` is equal to 1 for the bitstream, and the value of each constraint flag listed in Table A.7 is greater than or equal to the value(s) specified in the row of Table A.7 for the screen content coding extensions profile for which the decoder conformance is evaluated, and `general_max_422chroma_constraint_flag` is equal to `general_max_420chroma_constraint_flag`.
 - `sub_layer_profile_idc[i]` is equal to 4 or `sub_layer_profile_compatibility_flag[i][4]` is equal to 1 or `sub_layer_profile_idc[i]` is equal to 11 or `sub_layer_profile_compatibility_flag[i][11]` is equal to 1 for the sub-layer representation, and the value of each constraint flag listed in Table A.7 is greater than or equal to the value(s) specified in the row of Table A.7 for the screen content coding extensions profile for which the decoder conformance is evaluated, and `general_max_422chroma_constraint_flag` is equal to `general_max_420chroma_constraint_flag`, with each of the syntax elements in Table A.7 being replaced by its *i*-th corresponding sub-layer syntax element, respectively.
- The bitstream or sub-layer representation is indicated to conform to a level that is not level 8.5 and is lower than or equal to the specified level.
- The bitstream or sub-layer representation is indicated to conform to a tier that is lower than or equal to the specified tier.

A.4 Tiers and levels

A.4.1 General tier and level limits

For purposes of comparison of tier capabilities, the tier with `general_tier_flag` or `sub_layer_tier_flag[i]` equal to 0 is considered to be a lower tier than the tier with `general_tier_flag` or `sub_layer_tier_flag[i]` equal to 1.

For purposes of comparison of level capabilities, a particular level of a specific tier is considered to be a lower level than some other level of the same tier when the value of the `general_level_idc` or `sub_layer_level_idc[i]` of the particular level is less than that of the other level.

The following is specified for expressing the constraints in this annex:

- Let access unit *n* be the *n*-th access unit in decoding order, with the first access unit being access unit 0 (i.e., the 0-th access unit).
- Let picture *n* be the coded picture or the corresponding decoded picture of access unit *n*.

When the specified level is not level 8.5, bitstreams conforming to a profile at a specified tier and level shall obey the following constraints for each bitstream conformance test as specified in Annex C:

- a) `PicSizeInSamplesY` shall be less than or equal to `MaxLumaPs`, where `MaxLumaPs` is specified in Table A.8.
- b) The value of `pic_width_in_luma_samples` shall be less than or equal to $\text{Sqrt}(\text{MaxLumaPs} * 8)$.
- c) The value of `pic_height_in_luma_samples` shall be less than or equal to $\text{Sqrt}(\text{MaxLumaPs} * 8)$.
- d) For level 5 and higher levels, the value of `CtbSizeY` shall be equal to 32 or 64.
- e) The value of `NumPicTotalCurr` shall be less than or equal to 8.
- f) The value of `num_tile_columns_minus1` shall be less than `MaxTileCols` and `num_tile_rows_minus1` shall be less than `MaxTileRows`, where `MaxTileCols` and `MaxTileRows` are specified in Table A.8.
- g) For the VCL HRD parameters, `CpbSize[i]` shall be less than or equal to `CpbVclFactor * MaxCPB` for at least one value of *i* in the range of 0 to `cpb_cnt_minus1[HighestTid]`, inclusive, where `CpbSize[i]` is specified in clause E.3.3 based on parameters selected as specified in clause C.1, `CpbVclFactor` is specified in Table A.10, and `MaxCPB` is specified in Table A.8 in units of `CpbVclFactor` bits.
- h) For the NAL HRD parameters, `CpbSize[i]` shall be less than or equal to `CpbNalFactor * MaxCPB` for at least one value of *i* in the range of 0 to `cpb_cnt_minus1[HighestTid]`, inclusive, where `CpbSize[i]` is specified in clause E.3.3 based on parameters selected as specified in clause C.1, `CpbNalFactor` is specified in Table A.10, and `MaxCPB` is specified in Table A.8 in units of `CpbNalFactor` bits.

Table A.8 specifies the limits for each level of each tier for levels other than level 8.5.

A tier and level to which a bitstream conforms are indicated by the syntax elements `general_tier_flag` and `general_level_idc`, and a tier and level to which a sub-layer representation conforms are indicated by the syntax elements `sub_layer_tier_flag[i]` and `sub_layer_level_idc[i]`, as follows:

- If the specified level is not level 8.5, `general_tier_flag` or `sub_layer_tier_flag[i]` equal to 0 indicates conformance to the Main tier, `general_tier_flag` or `sub_layer_tier_flag[i]` equal to 1 indicates conformance to the High tier, according to the tier constraints specified in Table A.8 and `general_tier_flag` and `sub_layer_tier_flag[i]` shall be equal to 0 for levels below level 4 (corresponding to the entries in Table A.8 marked with "-"). Otherwise (the specified level is level 8.5), it is a requirement of bitstream conformance that `general_tier_flag` and `sub_layer_tier_flag[i]` shall be equal to 1 and the value 0 for `general_tier_flag` and `sub_layer_tier_flag[i]` is reserved for future use by ITU-T | ISO/IEC and decoders shall ignore the value of `general_tier_flag` and `sub_layer_tier_flag[i]`.
- `general_level_idc` and `sub_layer_level_idc[i]` shall be set equal to a value of 30 times the level number specified in Table A.8.

Table A.8 – General tier and level limits

Level	Max luma picture size MaxLumaPs (samples)	Max CPB size MaxCPB (CpbVclFactor or CpbNalFactor bits)		Max slice segments per picture MaxSliceSegmentsPerPicture	Max # of tile rows MaxTileRows	Max # of tile columns MaxTileCols
		Main tier	High tier			
1	36 864	350	-	16	1	1
2	122 880	1 500	-	16	1	1
2.1	245 760	3 000	-	20	1	1
3	552 960	6 000	-	30	2	2
3.1	983 040	10 000	-	40	3	3
4	2 228 224	12 000	30 000	75	5	5
4.1	2 228 224	20 000	50 000	75	5	5
5	8 912 896	25 000	100 000	200	11	10
5.1	8 912 896	40 000	160 000	200	11	10
5.2	8 912 896	60 000	240 000	200	11	10
6	35 651 584	60 000	240 000	600	22	20
6.1	35 651 584	120 000	480 000	600	22	20
6.2	35 651 584	240 000	800 000	600	22	20

A.4.2 Profile-specific level limits for the video profiles

NOTE – The term "video profiles", as used in this clause, refers to those profiles that are not still picture profiles. The still picture profiles include the Main Still Picture, Main 10 Still Picture, Main 4:4:4 Still Picture, and Main 4:4:4 16 Still Picture profiles.

The following is specified for expressing the constraints in this annex:

- Let the variable fR be set equal to $1 \div 300$.

The variable HbrFactor is defined as follows:

- If the bitstream or sub-layer representation is indicated to conform to the Main profile or the Main 10 profile, HbrFactor is set equal to 1.
- Otherwise, if the bitstream or sub-layer representation is indicated to conform to the High Throughput 4:4:4, High Throughput 4:4:4 10, High Throughput 4:4:4 14, Screen-Extended High Throughput 4:4:4, Screen-Extended High Throughput 4:4:4 10, or Screen-Extended High Throughput 4:4:4 14 profile, HbrFactor is set equal to 6.
- Otherwise, if the bitstream or sub-layer representation is indicated to conform to the High Throughput 4:4:4 16 Intra profile, HbrFactor is set equal to $24 - (12 * \text{general_lower_bit_rate_constraint_flag})$ or $24 - (12 * \text{sub_layer_lower_bit_rate_constraint_flag}[i])$.
- Otherwise, HbrFactor is set equal to $2 - \text{general_lower_bit_rate_constraint_flag}$ or $2 - \text{sub_layer_lower_bit_rate_constraint_flag}[i]$.

The variable BrVclFactor, which represents the VCL bit rate scale factor, is set equal to $\text{CpbVclFactor} * \text{HbrFactor}$.

The variable BrNalFactor, which represents the NAL bit rate scale factor, is set equal to $\text{CpbNalFactor} * \text{HbrFactor}$.

The variable MinCr is set equal to $\text{MinCrBase} * \text{MinCrScaleFactor} \div \text{HbrFactor}$.

When the specified level is not level 8.5, the value of $\text{sps_max_dec_pic_buffering_minus1}[\text{HighestTid}] + 1$ shall be less than or equal to MaxDpbSize, which is derived as follows:

$$\text{if(PicSizeInSamplesY } \leq (\text{MaxLumaPs} \gg 2)) \\ \text{MaxDpbSize} = \text{Min}(4 * \text{maxDpbPicBuf}, 16)$$

```

else if( PicSizeInSamplesY <= ( MaxLumaPs >> 1 ) )
    MaxDpbSize = Min( 2 * maxDpbPicBuf, 16 )
else if( PicSizeInSamplesY <= ( ( 3 * MaxLumaPs ) >> 2 ) )
    MaxDpbSize = Min( ( 4 * maxDpbPicBuf ) / 3, 16 )
else
    MaxDpbSize = maxDpbPicBuf

```

(A-2)

where MaxLumaPs is specified in Table A.8, and maxDpbPicBuf is equal to 6 for all profiles where the value of sps_curr_pic_ref_enabled_flag is required to be equal to 0 and 7 for all profiles where the value of sps_curr_pic_ref_enabled_flag is not required to be equal to 0.

Bitstreams and sub-layer representations conforming to the Monochrome, Monochrome 10, Monochrome 12, Monochrome 16, Main, Main 10, Main 12, Main 4:2:2 10, Main 4:2:2 12, Main 4:4:4 10, Main 4:4:4 12, Main Intra, Main 10 Intra, Main 12 Intra, Main 4:2:2 10 Intra, Main 4:2:2 12 Intra, Main 4:4:4 10 Intra, Main 4:4:4 12 Intra, Main 4:4:4 16 Intra High Throughput 4:4:4, High Throughput 4:4:4 10, High Throughput 4:4:4 14, High Throughput 4:4:4 16 Intra, Screen-Extended Main, Screen-Extended Main 10, Screen-Extended Main 4:4:4, Screen-Extended Main 4:4:4 10, Screen-Extended High Throughput 4:4:4, Screen-Extended High Throughput 4:4:4 10, or Screen-Extended High Throughput 4:4:4 14 profile at a specified tier and level shall obey the following constraints for each bitstream conformance test as specified in Annex C:

- a) The nominal removal time of access unit n (with n greater than 0) from the CPB, as specified in clause C.2.3, shall satisfy the constraint that $AuNominalRemovalTime[n] - AuCpbRemovalTime[n - 1]$ is greater than or equal to $\text{Max}(PicSizeInSamplesY \div MaxLumaSr, fR)$ for the value of $PicSizeInSamplesY$ of picture $n - 1$, where $MaxLumaSr$ is the value specified in Table A.9 that applies to picture $n - 1$.
- b) The difference between consecutive output times of pictures from the DPB, as specified in clause C.3.3, shall satisfy the constraint that $DpbOutputInterval[n]$ is greater than or equal to $\text{Max}(PicSizeInSamplesY \div MaxLumaSr, fR)$ for the value of $PicSizeInSamplesY$ of picture n , where $MaxLumaSr$ is the value specified in Table A.9 for picture n , provided that picture n is a picture that is output and is not the last picture of the bitstream that is output.
- c) The removal time of access unit 0 shall satisfy the constraint that the number of slice segments in picture 0 is less than or equal to $\text{Min}(\text{Max}(1, MaxSliceSegmentsPerPicture * MaxLumaSr / MaxLumaPs * (AuCpbRemovalTime[0] - AuNominalRemovalTime[0]) + MaxSliceSegmentsPerPicture * PicSizeInSamplesY / MaxLumaPs), MaxSliceSegmentsPerPicture)$, for the value of $PicSizeInSamplesY$ of picture 0, where $MaxSliceSegmentsPerPicture$, $MaxLumaPs$ and $MaxLumaSr$ are the values specified in Table A.8 and Table A.9, respectively, that apply to picture 0.
- d) The difference between consecutive CPB removal times of access units n and $n - 1$ (with n greater than 0) shall satisfy the constraint that the number of slice segments in picture n is less than or equal to $\text{Min}(\text{Max}(1, MaxSliceSegmentsPerPicture * MaxLumaSr / MaxLumaPs * (AuCpbRemovalTime[n] - AuCpbRemovalTime[n - 1])), MaxSliceSegmentsPerPicture)$, where $MaxSliceSegmentsPerPicture$, $MaxLumaPs$ and $MaxLumaSr$ are the values specified in Table A.8 and Table A.9 that apply to picture n .
- e) For the VCL HRD parameters, $BitRate[i]$ shall be less than or equal to $BrVclFactor * MaxBR$ for at least one value of i in the range of 0 to $cpb_cnt_minus1[HighestTid]$, inclusive, where $BitRate[i]$ is specified in clause E.3.3 based on parameters selected as specified in clause C.1 and $MaxBR$ is specified in Table A.9 in units of $BrVclFactor$ bits/s.
- f) For the NAL HRD parameters, $BitRate[i]$ shall be less than or equal to $BrNalFactor * MaxBR$ for at least one value of i in the range of 0 to $cpb_cnt_minus1[HighestTid]$, inclusive, where $BitRate[i]$ is specified in clause E.3.3 based on parameters selected as specified in clause C.1 and $MaxBR$ is specified in Table A.9 in units of $BrNalFactor$ bits/s.
- g) The sum of the $NumBytesInNalUnit$ variables for access unit 0 shall be less than or equal to $\text{FormatCapabilityFactor} * (\text{Max}(PicSizeInSamplesY, fR * MaxLumaSr) + MaxLumaSr * (AuCpbRemovalTime[0] - AuNominalRemovalTime[0])) \div MinCr$ for the value of $PicSizeInSamplesY$ of picture 0, where $MaxLumaSr$ and $FormatCapabilityFactor$ are the values specified in Table A.9 and Table A.10, respectively, that apply to picture 0.
- h) The sum of the $NumBytesInNalUnit$ variables for access unit n (with n greater than 0) shall be less than or equal to $\text{FormatCapabilityFactor} * MaxLumaSr * (AuCpbRemovalTime[n] - AuCpbRemovalTime[n - 1]) \div MinCr$, where $MaxLumaSr$ and $FormatCapabilityFactor$ are the values specified in Table A.9 and Table A.10, respectively, that apply to picture n .
- i) The removal time of access unit 0 shall satisfy the constraint that the number of tiles in picture 0 is less than or equal to $\text{Min}(\text{Max}(1, MaxTileCols * MaxTileRows * 120 * (AuCpbRemovalTime[0] -$

$AuNominalRemovalTime[0]) + MaxTileCols * MaxTileRows * PicSizeInSamplesY / MaxLumaPs$), $MaxTileCols * MaxTileRows$), for the value of $PicSizeInSamplesY$ of picture 0, where $MaxTileCols$ and $MaxTileRows$ are the values specified in Table A.8 that apply to picture 0.

- j) The difference between consecutive CPB removal times of access units n and $n - 1$ (with n greater than 0) shall satisfy the constraint that the number of tiles in picture n is less than or equal to $Min(Max(1, MaxTileCols * MaxTileRows * 120 * (AuCpbRemovalTime[n] - AuCpbRemovalTime[n - 1])), MaxTileCols * MaxTileRows)$, where $MaxTileCols$ and $MaxTileRows$ are the values specified in Table A.8 that apply to picture n .

k)

Table A.9 – Tier and level limits for the video profiles

Level	Max luma sample rate MaxLumaSr (samples/sec)	Max bit rate MaxBR (BrVclFactor or BrNalFactor bits/s)		Min compression ratio MinCBase	
		Main tier	High tier	Main tier	High tier

Informative clause A.4.3 shows the effect of these limits on picture rates for several example picture formats.

A.4.3 Effect of level limits on picture rate for the video profiles (informative)

This clause does not form an integral part of this Specification.

Informative Tables A.11 and A.12 provide examples of maximum picture rates for the Monochrome, Monochrome 10, Monochrome 12, Monochrome 16, Main, Main 10, Main 12, Main 4:2:2 10, Main 4:2:2 12, Main 4:4:4, Main 4:4:4 10, Main 4:4:4 12, Main Intra, Main 10 Intra, Main 12 Intra, Main 4:2:2 10 Intra, Main 4:2:2 12 Intra, Main 4:4:4 Intra, Main 4:4:4 10 Intra, Main 4:4:4 12 Intra, Main 4:4:4 16 Intra and High Throughput 4:4:4 16 Intra profiles for various picture formats when MinCbSizeY is equal to 64.

**Table A.11 – Maximum picture rates (pictures per second) at level 1 to 4.1 for some example picture sizes
when MinCbSizeY is equal to 64**

Level:				1	2	2.1	3	3.1	4	4.1

8192x4320	8 192	4 320	35 651 584	-	-	-	30.0	60.0	120.0

The following should be noted in regard to the examples shown in Tables A.11 and A.12:

- This is a variable-picture-size Specification. The specific listed picture sizes are illustrative examples only.
- The example luma picture sizes were computed by rounding up the luma width and luma height to multiples of 64 before computing the product of these quantities, to reflect the potential use of MinCbSizeY equal to 64 for these picture sizes, as pic_width_in_luma_samples and pic_height_in_luma_samples are each required to be a multiple of MinCbSizeY. For some illustrated values of luma width and luma height, a somewhat higher number of pictures per second can be supported when MinCbSizeY is less than 64.

- In cases where the maximum picture rate value is not an integer multiple of 0.1 pictures per second, the given maximum picture rate values have been rounded down to the largest integer multiple of 0.1 frames per second that does not exceed the exact value. For example, for level 3.1, the maximum picture rate for 720p HD has been rounded down to 33.7 from an exact value of 33.75.
- As used in the examples, "525" refers to typical use for environments using 525 analogue scan lines (of which approximately 480 lines contain the visible picture region) and "625" refers to environments using 625 analogue scan lines (of which approximately 576 lines contain the visible picture region).
- XGA is also known as (aka) XVGA, 4SVGA aka UXGA, 16XGA aka 4Kx3K, CIF aka 625 SIF, 625 HHR aka 2CIF aka half 625 D-1, aka half 625 ITU-R BT.601, 525 SD aka 525 D-1 aka 525 ITU-R BT.601, 625 SD aka 625 D-1 aka 625 ITU-R BT.601.

Annex B

Byte stream format

(This annex forms an integral part of this Recommendation | International Standard.)

B.1 General

This annex specifies syntax and semantics of a byte stream format specified for use by applications that deliver some or all of the NAL unit stream as an ordered stream of bytes or bits within which the locations of NAL unit boundaries need to be identifiable from patterns in the data, such as Rec. ITU-T H.222.0 | ISO/IEC 13818-1 systems or Recommendation ITU-T H.320 systems. For bit-oriented delivery, the bit order for the byte stream format is specified to start with the MSB of the first byte, proceed to the LSB of the first byte, followed by the MSB of the second byte, etc.

The byte stream format consists of a sequence of byte stream NAL unit syntax structures. Each byte stream NAL unit syntax structure contains one start code prefix followed by one `nal_unit(NumBytesInNalUnit)` syntax structure. It may (and under some circumstances, it shall) also contain an additional `zero_byte` syntax element. It may also contain one or more additional trailing `zero_8bits` syntax elements. When it is the first byte stream NAL unit in the bitstream, it may also contain one or more additional leading `zero_8bits` syntax elements.

B.2 Byte stream NAL unit syntax and semantics

B.2.1 Byte stream NAL unit syntax

<code>byte_stream_nal_unit(NumBytesInNalUnit) {</code>	Descriptor
<code>while(next_bits(24) != 0x000001 && next_bits(32) != 0x00000001)</code>	
<code> leading_zero_8bits /* equal to 0x00 */</code>	f(8)
<code>if(next_bits(24) != 0x000001)</code>	
<code> zero_byte /* equal to 0x00 */</code>	f(8)
<code> start_code_prefix_one_3bytes /* equal to 0x000001 */</code>	f(24)
<code> nal_unit(NumBytesInNalUnit)</code>	
<code> while(more_data_in_byte_stream() && next_bits(24) != 0x000001 && next_bits(32) != 0x00000001)</code>	
<code> trailing_zero_8bits /* equal to 0x00 */</code>	f(8)
<code>}</code>	

B.2.2 Byte stream NAL unit semantics

The order of byte stream NAL units in the byte stream shall follow the decoding order of the NAL units contained in the byte stream NAL units (see clause 7.4.2.4). The content of each byte stream NAL unit is associated with the same access unit as the NAL unit contained in the byte stream NAL unit (see clause 7.4.2.4.4).

leading_zero_8bits is a byte equal to 0x00.

NOTE – The `leading_zero_8bits` syntax element can only be present in the first byte stream NAL unit of the bitstream, because (as shown in the syntax diagram of clause B.2.1) any bytes equal to 0x00 that follow a NAL unit syntax structure and precede the four-byte sequence 0x00000001 (which is to be interpreted as a `zero_byte` followed by a `start_code_prefix_one_3bytes`) will be considered to be `trailing_zero_8bits` syntax elements that are part of the preceding byte stream NAL unit.

zero_byte is a single byte equal to 0x00.

When one or more of the following conditions are true, the `zero_byte` syntax element shall be present:

- The `nal_unit_type` within the `nal_unit()` syntax structure is equal to `VPS_NUT`, `SPS_NUT` or `PPS_NUT`.
- The byte stream NAL unit syntax structure contains the first NAL unit of an access unit in decoding order, as specified in clause 7.4.2.4.4.

start_code_prefix_one_3bytes is a fixed-value sequence of 3 bytes equal to 0x000001. This syntax element is called a start code prefix.

trailing_zero_8bits is a byte equal to 0x00.

B.3 Byte stream NAL unit decoding process

Input to this process consists of an ordered stream of bytes consisting of a sequence of byte stream NAL unit syntax structures.

Output of this process consists of a sequence of NAL unit syntax structures.

At the beginning of the decoding process, the decoder initializes its current position in the byte stream to the beginning of the byte stream. It then extracts and discards each `leading_zero_8bits` syntax element (when present), moving the current position in the byte stream forward one byte at a time, until the current position in the byte stream is such that the next four bytes in the bitstream form the four-byte sequence `0x00000001`.

The decoder then performs the following step-wise process repeatedly to extract and decode each NAL unit syntax structure in the byte stream until the end of the byte stream has been encountered (as determined by unspecified means) and the last NAL unit in the byte stream has been decoded:

1. When the next four bytes in the bitstream form the four-byte sequence `0x00000001`, the next byte in the byte stream (which is a `zero_byte` syntax element) is extracted and discarded and the current position in the byte stream is set equal to the position of the byte following this discarded byte.
2. The next three-byte sequence in the byte stream (which is a `start_code_prefix_one_3bytes`) is extracted and discarded and the current position in the byte stream is set equal to the position of the byte following this three-byte sequence.
3. `NumBytesInNalUnit` is set equal to the number of bytes starting with the byte at the current position in the byte stream up to and including the last byte that precedes the location of one or more of the following conditions:
 - A subsequent byte-aligned three-byte sequence equal to `0x0000000`,
 - A subsequent byte-aligned three-byte sequence equal to `0x0000001`,
 - The end of the byte stream, as determined by unspecified means.
4. `NumBytesInNalUnit` bytes are removed from the bitstream and the current position in the byte stream is advanced by `NumBytesInNalUnit` bytes. This sequence of bytes is `nal_unit(NumBytesInNalUnit)` and is decoded using the NAL unit decoding process.
5. When the current position in the byte stream is not at the end of the byte stream (as determined by unspecified means) and the next bytes in the byte stream do not start with a three-byte sequence equal to `0x0000001` and the next bytes in the byte stream do not start with a four byte sequence equal to `0x00000001`, the decoder extracts and discards each `trailing_zero_8bits` syntax element, moving the current position in the byte stream forward one byte at a time, until the current position in the byte stream is such that the next bytes in the byte stream form the four-byte sequence `0x00000001` or the end of the byte stream has been encountered (as determined by unspecified means).

B.4 Decoder byte-alignment recovery (informative)

This clause does not form an integral part of this Specification.

Many applications provide data to a decoder in a manner that is inherently byte aligned, and thus have no need for the bit-oriented byte alignment detection procedure described in this clause.

A decoder is said to have byte alignment with a bitstream when the decoder has determined whether or not the positions of data in the bitstream are byte-aligned. When a decoder does not have byte alignment with the bitstream, the decoder may examine the incoming bitstream for the binary pattern '00000000 00000000 00000000 00000001' (31 consecutive bits equal to 0 followed by a bit equal to 1). The bit immediately following this pattern is the first bit of an aligned byte following a start code prefix. Upon detecting this pattern, the decoder will be byte-aligned with the bitstream and positioned at the start of a NAL unit in the bitstream.

Once byte aligned with the bitstream, the decoder can examine the incoming bitstream data for subsequent three-byte sequences `0x0000001` and `0x0000003`.

When the three-byte sequence `0x0000001` is detected, this is a start code prefix.

When the three-byte sequence `0x0000003` is detected, the third byte (`0x03`) is an `emulation_prevention_three_byte` to be discarded as specified in clause 7.4.2.

When an error in the bitstream syntax is detected (e.g., a non-zero value of the `forbidden_zero_bit` or one of the three-byte or four-byte sequences that are prohibited in clause 7.4.2), the decoder may consider the detected condition as an indication that byte alignment may have been lost and may discard all bitstream data until the detection of byte alignment at a later position in the bitstream as described above in this clause.

Annex C

Hypothetical reference decoder

(This annex forms an integral part of this Recommendation | International Standard.)

C.1 General

This annex specifies the hypothetical reference decoder (HRD) and its use to check bitstream and decoder conformance.

Two types of bitstreams or bitstream subsets are subject to HRD conformance checking for this Specification. The first type, called a Type I bitstream, is a NAL unit stream containing only the VCL NAL units and NAL units with `nal_unit_type` equal to `FD_NUT` (filler data NAL units) for all access units in the bitstream. The second type, called a Type II bitstream, contains, in addition to the VCL NAL units and filler data NAL units for all access units in the bitstream, at least one of the following:

- additional non-VCL NAL units other than filler data NAL units,
- all `leading_zero_8bits`, `zero_byte`, `start_code_prefix_one_3bytes` and `trailing_zero_8bits` syntax elements that form a byte stream from the NAL unit stream (as specified in Annex B).

NOTE 1 – Decoders conforming to profiles specified in Annex A do not use NAL units with `nuh_layer_id` greater than 0 (e.g., access unit delimiter NAL units with `nuh_layer_id` greater than 0) for access unit boundary detection, except for identification of whether a NAL unit is a VCL or non-VCL NAL unit. Consequently, hypothetical reference decoder (HRD) parameters carried in non-scalable-nested buffering period, picture timing and decoding unit information SEI messages apply to access units that are identified based on such access unit boundary detection.

Figure C.1 shows the types of bitstream conformance points checked by the HRD.

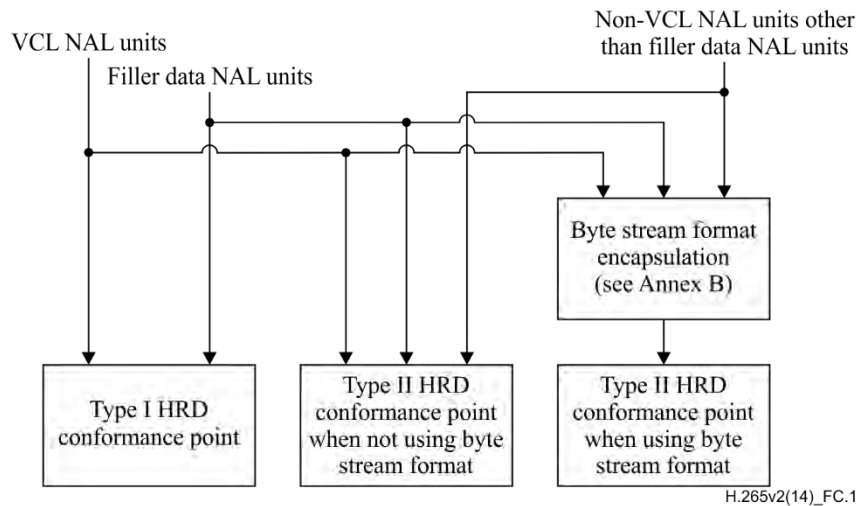

Figure C.1 – Structure of byte streams and NAL unit streams for HRD conformance checks

The syntax elements of non-VCL NAL units (or their default values for some of the syntax elements), required for the HRD, are specified in the semantic clauses of clause 7, Annexes D and E.

Two types of HRD parameter sets (NAL HRD parameters and VCL HRD parameters) are used. The HRD parameter sets are signalled through the `hrd_parameters()` syntax structure, which may be part of the SPS syntax structure or the VPS syntax structure.

Two sets of bitstream conformance tests are needed for checking the conformance of a bitstream, which is referred to as the entire bitstream, denoted as `entireBitstream`. The first set of bitstream conformance tests are for testing the conformance of the entire bitstream and its temporal subsets, regardless of whether there is a layer set specified by the active VPS that contains all the `nuh_layer_id` values of VCL NAL units present in the entire bitstream. The second set of bitstream conformance tests are for testing the conformance of the layer sets specified by the active VPS and their temporal subsets. For all these tests, only the base layer pictures (i.e., pictures with `nuh_layer_id` equal to 0) are decoded and other pictures are ignored by the decoder when the decoding process is invoked.

For each test, the following ordered steps apply in the order listed, followed by the processes described after these steps in this clause:

1. An operation point under test, denoted as TargetOp, is selected by selecting a layer identifier list OpLayerIdList and a target highest TemporalId value OpTid. The layer identifier list OpLayerIdList of TargetOp either consists of all the nuh_layer_id values of the VCL NAL units present in entireBitstream or consists of all the nuh_layer_id values of a layer set specified by the active VPS. The value of OpTid is in the range of 0 to sps_max_sub_layers_minus1, inclusive. The values of OpLayerIdList and OpTid are such that the sub-bitstream BitstreamToDecode that is the output by invoking the sub-bitstream extraction process as specified in clause 10 with entireBitstream, OpTid and OpLayerIdList as inputs satisfy both of the following conditions:
 - There is at least one VCL NAL unit in BitstreamToDecode with nuh_layer_id equal to each of the nuh_layer_id values in OpLayerIdList.
 - There is at least one VCL NAL unit with TemporalId equal to OpTid in BitstreamToDecode.
2. TargetDecLayerIdList is set equal to OpLayerIdList of TargetOp and HighestTid is set equal to OpTid of TargetOp.
3. The hrd_parameters() syntax structure and the sub_layer_hrd_parameters() syntax structure applicable to TargetOp are selected. If TargetDecLayerIdList contains all nuh_layer_id values present in entireBitstream, the hrd_parameters() syntax structure in the active SPS (or provided through an external means not specified in this Specification) is selected. Otherwise, the hrd_parameters() syntax structure in the active VPS (or provided through some external means not specified in this Specification) that applies to TargetOp is selected. Within the selected hrd_parameters() syntax structure, if BitstreamToDecode is a Type I bitstream, the sub_layer_hrd_parameters(HighestTid) syntax structure that immediately follows the condition "if(vcl_hrd_parameters_present_flag)" is selected and the variable NalHrdModeFlag is set equal to 0; otherwise (BitstreamToDecode is a Type II bitstream), the sub_layer_hrd_parameters(HighestTid) syntax structure that immediately follows either the condition "if(vcl_hrd_parameters_present_flag)" (in this case the variable NalHrdModeFlag is set equal to 0) or the condition "if(nal_hrd_parameters_present_flag)" (in this case the variable NalHrdModeFlag is set equal to 1) is selected. When BitstreamToDecode is a Type II bitstream and NalHrdModeFlag is equal to 0, all non-VCL NAL units except filler data NAL units, and all leading_zero_8bits, zero_byte, start_code_prefix_one_3bytes and trailing_zero_8bits syntax elements that form a byte stream from the NAL unit stream (as specified in Annex B), when present, are discarded from BitstreamToDecode and the remaining bitstream is assigned to BitstreamToDecode.
4. An access unit associated with a buffering period SEI message (present in BitstreamToDecode or available through external means not specified in this Specification) applicable to TargetOp is selected as the HRD initialization point and referred to as access unit 0. If TargetDecLayerIdList contains all nuh_layer_id values present in entireBitstream, the associated buffering period SEI message shall be either a non-scalable-nested SEI message or provided by external means. Otherwise, the associated buffering period SEI message shall be either a scalable-nested SEI message or provided by external means.
5. When sub_pic_hrd_params_present_flag in the selected hrd_parameters() syntax structure is equal to 1, the CPB is scheduled to operate either at the access unit level (in which case the variable SubPicHrdFlag is set equal to 0) or at the sub-picture level (in which case the variable SubPicHrdFlag is set equal to 1). Otherwise, SubPicHrdFlag is set equal to 0 and the CPB is scheduled to operate at the partition unit level.
6. For each access unit in BitstreamToDecode starting from access unit 0, the buffering period SEI message (present in BitstreamToDecode or available through external means not specified in this Specification) that is associated with the access unit and applies to TargetOp is selected, the picture timing SEI message (present in BitstreamToDecode or available through external means not specified in this Specification) that is associated with the access unit and applies to TargetOp is selected, and when SubPicHrdFlag is equal to 1 and sub_pic_cpb_params_in_pic_timing_sei_flag is equal to 0, the decoding unit information SEI messages (present in BitstreamToDecode or available through external means not specified in this Specification) that are associated with decoding units in the access unit and apply to TargetOp are selected. If TargetDecLayerIdList contains all nuh_layer_id values present in entireBitstream, the selected buffering period, picture timing and decoding unit information SEI messages shall be either non-scalable-nested SEI messages or provided by external means. Otherwise, the selected buffering period, picture timing and decoding unit information SEI messages shall be either scalable-nested SEI messages or provided by external means.
7. A value of SchedSelIdx is selected. The selected SchedSelIdx shall be in the range of 0 to cpb_cnt_minus1[HighestTid], inclusive, where cpb_cnt_minus1[HighestTid] is found in the hrd_parameters() syntax structure as selected above.
8. When the coded picture in access unit 0 has nal_unit_type equal to CRA_NUT or BLA_W_LP and irap_cpb_params_present_flag in the selected buffering period SEI message is equal to 1, either of the following applies for selection of the initial CPB removal delay and delay offset:
 - If NalHrdModeFlag is equal to 1, the default initial CPB removal delay and delay offset represented by nal_initial_cpb_removal_delay[SchedSelIdx] and nal_initial_cpb_removal_offset[SchedSelIdx], respectively, in the selected buffering period SEI message are selected. Otherwise, the default initial CPB

removal delay and delay offset represented by `vcl_initial_cpb_removal_delay[SchedSelIdx]` and `vcl_initial_cpb_removal_offset[SchedSelIdx]`, respectively, in the selected buffering period SEI message are selected. The variable `DefaultInitCpbParamsFlag` is set equal to 1.

- If `NalHrdModeFlag` is equal to 1, the alternative initial CPB removal delay and delay offset represented by `nal_initial_alt_cpb_removal_delay[SchedSelIdx]` and `nal_initial_alt_cpb_removal_offset[SchedSelIdx]`, respectively, in the selected buffering period SEI message are selected. Otherwise, the alternative initial CPB removal delay and delay offset represented by `vcl_initial_alt_cpb_removal_delay[SchedSelIdx]` and `vcl_initial_alt_cpb_removal_offset[SchedSelIdx]`, respectively, in the selected buffering period SEI message are selected. The variable `DefaultInitCpbParamsFlag` is set equal to 0, and the RASL access units associated with access unit 0 are discarded from `BitstreamToDecode` and the remaining bitstream is assigned to `BitstreamToDecode`.

Each conformance test consists of a combination of one option in each of the above steps. When there is more than one option for a step, for any particular conformance test only one option is chosen. All possible combinations of all the steps form the entire set of conformance tests. For each operation point under test, the number of bitstream conformance tests to be performed is equal to $n0 * n1 * (n2 * 2 + n3) * n4$, where the values of $n0$, $n1$, $n2$, $n3$ and $n4$ are specified as follows:

- $n0$ is derived as follows:
 - If `BitstreamToDecode` is a Type I bitstream, $n0$ is equal to 1.
 - Otherwise (`BitstreamToDecode` is a Type II bitstream), $n0$ is equal to 2.
- $n1$ is equal to `cpb_cnt_minus1[HighestTid] + 1`.
- $n2$ is the number of access units in `BitstreamToDecode` that each is associated with a buffering period SEI message applicable to `TargetOp` and for each of which both of the following conditions are true:
 - `nal_unit_type` is equal to `CRA_NUT` or `BLA_W_LP` for the VCL NAL units.
 - The associated buffering period SEI message applicable to `TargetOp` has `irap_cpb_params_present_flag` equal to 1.
- $n3$ is the number of access units in `BitstreamToDecode` that each is associated with a buffering period SEI message applicable to `TargetOp` and for each of which one or both of the following conditions are true:
 - `nal_unit_type` is equal to neither `CRA_NUT` nor `BLA_W_LP` for the VCL NAL units.
 - The associated buffering period SEI message applicable to `TargetOp` has `irap_cpb_params_present_flag` equal to 0.
- $n4$ is derived as follows:
 - If `sub_pic_hrd_params_present_flag` in the selected `hrd_parameters()` syntax structure is equal to 0, $n4$ is equal to 1.
 - Otherwise, $n4$ is equal to 2.

When `BitstreamToDecode` is a Type II bitstream, the following applies:

- If the `sub_layer_hrd_parameters(HighestTid)` syntax structure that immediately follows the condition "`if(vcl_hrd_parameters_present_flag)`" is selected, the test is conducted at the Type I conformance point shown in Figure C.1, and only VCL and filler data NAL units are counted for the input bit rate and CPB storage.
- Otherwise (the `sub_layer_hrd_parameters(HighestTid)` syntax structure that immediately follows the condition "`if(nal_hrd_parameters_present_flag)`" is selected), the test is conducted at the Type II conformance point shown in Figure C.1, and all bytes of the Type II bitstream, which may be a NAL unit stream or a byte stream, are counted for the input bit rate and CPB storage.

NOTE 2 – NAL HRD parameters established by a value of `SchedSelIdx` for the Type II conformance point shown in Figure C.1 are sufficient to also establish VCL HRD conformance for the Type I conformance point shown in Figure C.1 for the same values of `InitCpbRemovalDelay[SchedSelIdx]`, `BitRate[SchedSelIdx]` and `CpbSize[SchedSelIdx]` for the variable bit rate (VBR) case (`cbr_flag[SchedSelIdx]` equal to 0). This is because the data flow into the Type I conformance point is a subset of the data flow into the Type II conformance point and because, for the VBR case, the CPB is allowed to become empty and stay empty until the time a next picture is scheduled to begin to arrive. For example, when decoding a CVS conforming to one or more of the profiles specified in Annex A using the decoding process specified in clauses 2 through 10, when NAL HRD parameters are provided for the Type II conformance point that not only fall within the bounds set for NAL HRD parameters for profile conformance in item f) of clause A.4.2 but also fall within the bounds set for VCL HRD parameters for profile conformance in item e) of clause A.4.2, conformance of the VCL HRD for the Type I conformance point is also assured to fall within the bounds of item e) of clause A.4.2.

All VPSs, SPSs and PPSs referred to in the VCL NAL units and the corresponding buffering period, picture timing and decoding unit information SEI messages shall be conveyed to the HRD, in a timely manner, either in the bitstream (by non-VCL NAL units), or by other means not specified in this Specification.

In Annexes C, D and E, the specification for "presence" of non-VCL NAL units that contain VPSs, SPSs, PPSs, buffering period SEI messages, picture timing SEI messages or decoding unit information SEI messages is also satisfied when those

NAL units (or just some of them) are conveyed to decoders (or to the HRD) by other means not specified in this Specification. For the purpose of counting bits, only the appropriate bits that are actually present in the bitstream are counted.

NOTE 3 – As an example, synchronization of such a non-VCL NAL unit, conveyed by means other than presence in the bitstream, with the NAL units that are present in the bitstream, can be achieved by indicating two points in the bitstream, between which the non-VCL NAL unit would have been present in the bitstream, had the encoder decided to convey it in the bitstream.

When the content of such a non-VCL NAL unit is conveyed for the application by some means other than presence within the bitstream, the representation of the content of the non-VCL NAL unit is not required to use the same syntax as specified in this Specification.

NOTE 4 – When HRD information is contained within the bitstream, it is possible to verify the conformance of a bitstream to the requirements of this clause based solely on information contained in the bitstream. When the HRD information is not present in the bitstream, as is the case for all "stand-alone" Type I bitstreams, conformance can only be verified when the HRD data are supplied by some other means not specified in this Specification.

The HRD contains a coded picture buffer (CPB), an instantaneous decoding process, a decoded picture buffer (DPB), and output cropping as shown in Figure C.2.

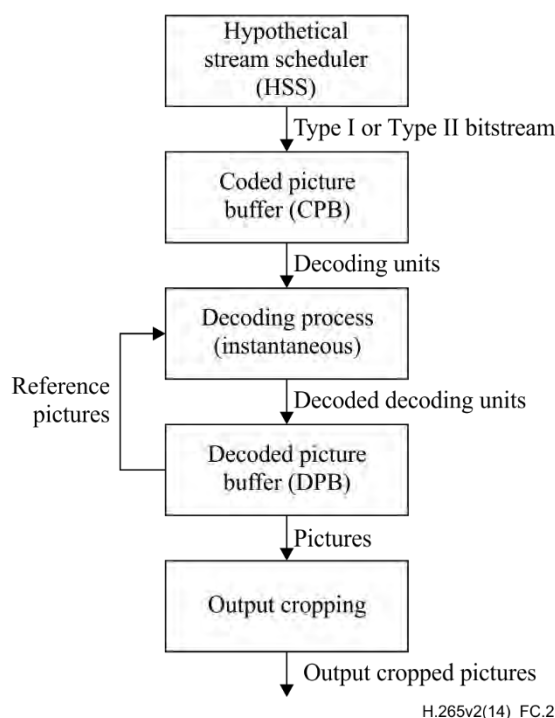

Figure C.2 – HRD buffer model

For each bitstream conformance test, the CPB size (number of bits) is $CpbSize[SchedSelIdx]$ as specified in clause E.3.3, where $SchedSelIdx$ and the HRD parameters are specified above in this clause. The DPB size (number of picture storage buffers) is $sps_max_dec_pic_buffering_minus1[HighestTid] + 1$.

If $SubPicHrdFlag$ is equal to 0, the HRD operates at access unit level and each decoding unit is an access unit. Otherwise the HRD operates at sub-picture level and each decoding unit is a subset of an access unit.

NOTE 5 – If the HRD operates at access unit level, each time when some bits are removed from the CPB, a decoding unit that is an entire access unit is removed from the CPB. Otherwise (the HRD operates at sub-picture level), each time when some bits are removed from the CPB, a decoding unit that is a subset of an access unit is removed from the CPB. Regardless of whether the HRD operates at access unit level or sub-picture level, each time when some picture is output from the DPB, an entire decoded picture is output from the DPB, though the picture output time is derived based on the differently derived CPB removal times and the differently signalled DPB output delays.

The following is specified for expressing the constraints in this annex:

- Each access unit is referred to as access unit n , where the number n identifies the particular access unit. Access unit 0 is selected per step 4 above. The value of n is incremented by 1 for each subsequent access unit in decoding order.
- Each decoding unit is referred to as decoding unit m , where the number m identifies the particular decoding unit. The first decoding unit in decoding order in access unit 0 is referred to as decoding unit 0. The value of m is incremented by 1 for each subsequent decoding unit in decoding order.

NOTE 6 – The numbering of decoding units is relative to the first decoding unit in access unit 0.

- Picture *n* refers to the coded picture or the decoded picture of access unit *n*.

The HRD operates as follows:

- The HRD is initialized at decoding unit 0, with both the CPB and the DPB being set to be empty (the DPB fullness is set equal to 0).

NOTE 7 – After initialization, the HRD is not initialized again by subsequent buffering period SEI messages.

- Data associated with decoding units that flow into the CPB according to a specified arrival schedule are delivered by the hypothetical stream scheduler (HSS).
- The data associated with each decoding unit are removed and decoded instantaneously by the instantaneous decoding process at the CPB removal time of the decoding unit.
- Each decoded picture is placed in the DPB.
- A decoded picture is removed from the DPB when it becomes no longer needed for inter prediction reference and no longer needed for output.

For each bitstream conformance test, the operation of the CPB is specified in clause C.2, the instantaneous decoder operation is specified in clauses 2 through 10, the operation of the DPB is specified in clause C.3 and the output cropping is specified in clauses C.3.3 and C.5.2.2.

HSS and HRD information concerning the number of enumerated delivery schedules and their associated bit rates and buffer sizes is specified in clauses E.2.2 and E.3.2. The HRD is initialized as specified by the buffering period SEI message specified in clauses D.2.2 and D.3.2. The removal timing of decoding units from the CPB and output timing of decoded pictures from the DPB is specified using information in picture timing SEI messages (specified in clauses D.2.3 and 0) or in decoding unit information SEI messages (specified in clauses D.2.22 and D.3.22). All timing information relating to a specific decoding unit shall arrive prior to the CPB removal time of the decoding unit.

The requirements for bitstream conformance are specified in clause C.4 and the HRD is used to check conformance of bitstreams as specified above in this clause and to check conformance of decoders as specified in clause C.5.

NOTE 8 – While conformance is guaranteed under the assumption that all picture-rates and clocks used to generate the bitstream match exactly the values signalled in the bitstream, in a real system each of these may vary from the signalled or specified value.

All the arithmetic in this annex is performed with real values, so that no rounding errors can propagate. For example, the number of bits in a CPB just prior to or after removal of a decoding unit is not necessarily an integer.

The variable *ClockTick* is derived as follows and is called a clock tick:

$$\text{ClockTick} = \text{vui_num_units_in_tick} \div \text{vui_time_scale} \quad (\text{C-1})$$

The variable *ClockSubTick* is derived as follows and is called a clock sub-tick:

$$\text{ClockSubTick} = \text{ClockTick} \div (\text{tick_divisor_minus2} + 2) \quad (\text{C-2})$$

C.2 Operation of coded picture buffer

C.2.1 General

The specifications in this clause apply independently to each set of coded picture buffer (CPB) parameters that is present and to both the Type I and Type II conformance points shown in Figure C.1 and the set of CPB parameters is selected as specified in clause C.1.

C.2.2 Timing of decoding unit arrival

If *SubPicHrdFlag* is equal to 0, the variable *subPicParamsFlag* is set equal to 0 and the process specified in the remainder of this clause is invoked with a decoding unit being considered as an access unit, for derivation of the initial and final CPB arrival times for access unit *n*.

Otherwise (*SubPicHrdFlag* is equal to 1), the process specified in the remainder of this clause is first invoked with the variable *subPicParamsFlag* set equal to 0 and a decoding unit being considered as an access unit, for derivation of the initial and final CPB arrival times for access unit *n*, and then invoked with *subPicParamsFlag* set equal to 1 and a decoding unit being considered as a subset of an access unit, for derivation of the initial and final CPB arrival times for the decoding units in access unit *n*.

The variables *InitCpbRemovalDelay[SchedSelIdx]* and *InitCpbRemovalDelayOffset[SchedSelIdx]* are derived as follows:

- If one or more of the following conditions are true, `InitCpbRemovalDelay[SchedSelIdx]` and `InitCpbRemovalDelayOffset[SchedSelIdx]` are set equal to the values of the buffering period SEI message syntax elements `nal_initial_alt_cpb_removal_delay[SchedSelIdx]` and `nal_initial_alt_cpb_removal_offset[SchedSelIdx]`, respectively, when `NalHrdModeFlag` is equal to 1 or `vcl_initial_alt_cpb_removal_delay[SchedSelIdx]` and `vcl_initial_alt_cpb_removal_offset[SchedSelIdx]`, respectively, when `NalHrdModeFlag` is equal to 0, where the buffering period SEI message syntax elements are selected as specified in clause C.1:
 - Access unit 0 is a BLA access unit for which the coded picture has `nal_unit_type` equal to `BLA_W_RADL` or `BLA_N_LP`, and the value of `irap_cpb_params_present_flag` of the buffering period SEI message is equal to 1.
 - Access unit 0 is a BLA access unit for which the coded picture has `nal_unit_type` equal to `BLA_W_LP` or is a CRA access unit, and the value of `irap_cpb_params_present_flag` of the buffering period SEI message is equal to 1 and one or more of the following conditions are true:
 - `UseAltCpbParamsFlag` for access unit 0 is equal to 1.
 - `DefaultInitCpbParamsFlag` is equal to 0.
 - The value of `subPicParamsFlag` is equal to 1.
- Otherwise, `InitCpbRemovalDelay[SchedSelIdx]` and `InitCpbRemovalDelayOffset[SchedSelIdx]` are set equal to the values of the buffering period SEI message syntax elements `nal_initial_cpb_removal_delay[SchedSelIdx]` and `nal_initial_cpb_removal_offset[SchedSelIdx]`, respectively, when `NalHrdModeFlag` is equal to 1, or `vcl_initial_cpb_removal_delay[SchedSelIdx]` and `vcl_initial_cpb_removal_offset[SchedSelIdx]`, respectively, when `NalHrdModeFlag` is equal to 0, where the buffering period SEI message syntax elements are selected as specified in clause C.1.

The time at which the first bit of decoding unit `m` begins to enter the CPB is referred to as the initial arrival time `initArrivalTime[m]`.

The initial arrival time of decoding unit `m` is derived as follows:

- If the decoding unit is decoding unit 0 (i.e., when `m` is equal to 0), `initArrivalTime[0]` is set equal to 0.
- Otherwise (the decoding unit is decoding unit `m` with `m > 0`), the following applies:
 - If `cbr_flag[SchedSelIdx]` is equal to 1, the initial arrival time for decoding unit `m` is equal to the final arrival time (which is derived below) of decoding unit `m – 1`, i.e.,

$$\begin{aligned}
 &\text{if(!subPicParamsFlag)} \\
 &\quad \text{initArrivalTime[m]} = \text{AuFinalArrivalTime[m – 1]} \\
 &\text{else} \\
 &\quad \text{initArrivalTime[m]} = \text{DuFinalArrivalTime[m – 1]}
 \end{aligned}
 \tag{C-3}$$

- Otherwise (`cbr_flag[SchedSelIdx]` is equal to 0), the initial arrival time for decoding unit `m` is derived as follows:

$$\begin{aligned}
 &\text{if(!subPicParamsFlag)} \\
 &\quad \text{initArrivalTime[m]} = \text{Max(AuFinalArrivalTime[m – 1], initArrivalEarliestTime[m])} \\
 &\text{(C-4)} \\
 &\text{else} \\
 &\quad \text{initArrivalTime[m]} = \text{Max(DuFinalArrivalTime[m – 1], initArrivalEarliestTime[m])}
 \end{aligned}$$

where `initArrivalEarliestTime[m]` is derived as follows:

- The variable `tmpNominalRemovalTime` is derived as follows:

$$\begin{aligned}
 &\text{if(!subPicParamsFlag)} \\
 &\quad \text{tmpNominalRemovalTime} = \text{AuNominalRemovalTime[m]} \\
 &\text{else} \\
 &\quad \text{tmpNominalRemovalTime} = \text{DuNominalRemovalTime[m]}
 \end{aligned}
 \tag{C-5}$$

where `AuNominalRemovalTime[m]` and `DuNominalRemovalTime[m]` are the nominal CPB removal time of access unit `m` and decoding unit `m`, respectively, as specified in clause C.2.3.

- If decoding unit `m` is not the first decoding unit of a subsequent buffering period, `initArrivalEarliestTime[m]` is derived as follows:

$$\begin{aligned} \text{initArrivalEarliestTime}[m] = & \text{tmpNominalRemovalTime} - \\ & (\text{InitCpbRemovalDelay}[\text{SchedSelIdx}] \\ & + \text{InitCpbRemovalDelayOffset}[\text{SchedSelIdx}]) \div 90\,000 \end{aligned} \quad (\text{C-6})$$

- Otherwise (decoding unit m is the first decoding unit of a subsequent buffering period), $\text{initArrivalEarliestTime}[m]$ is derived as follows:

$$\begin{aligned} \text{initArrivalEarliestTime}[m] = & \text{tmpNominalRemovalTime} - \\ & (\text{InitCpbRemovalDelay}[\text{SchedSelIdx}] \div 90\,000) \end{aligned} \quad (\text{C-7})$$

The final arrival time for decoding unit m is derived as follows:

$$\begin{aligned} & \text{if(!subPicParamsFlag)} \\ & \quad \text{AuFinalArrivalTime}[m] = \text{initArrivalTime}[m] + \text{sizeInbits}[m] \div \text{BitRate}[\text{SchedSelIdx}] \quad (\text{C-8}) \\ & \text{else} \\ & \quad \text{DuFinalArrivalTime}[m] = \text{initArrivalTime}[m] + \text{sizeInbits}[m] \div \text{BitRate}[\text{SchedSelIdx}] \end{aligned}$$

where $\text{sizeInbits}[m]$ is the size in bits of decoding unit m , counting the bits of the VCL NAL units and the filler data NAL units for the Type I conformance point or all bits of the Type II bitstream for the Type II conformance point, where the Type I and Type II conformance points are as shown in Figure C.1.

The values of SchedSelIdx , $\text{BitRate}[\text{SchedSelIdx}]$ and $\text{CpbSize}[\text{SchedSelIdx}]$ are constrained as follows:

- If the content of the selected $\text{hrd_parameters}()$ syntax structures for the access unit containing decoding unit m and the previous access unit differ, the HSS selects a value SchedSelIdx1 of SchedSelIdx from among the values of SchedSelIdx provided in the selected $\text{hrd_parameters}()$ syntax structures for the access unit containing decoding unit m that results in a $\text{BitRate}[\text{SchedSelIdx1}]$ or $\text{CpbSize}[\text{SchedSelIdx1}]$ for the access unit containing decoding unit m . The value of $\text{BitRate}[\text{SchedSelIdx1}]$ or $\text{CpbSize}[\text{SchedSelIdx1}]$ may differ from the value of $\text{BitRate}[\text{SchedSelIdx0}]$ or $\text{CpbSize}[\text{SchedSelIdx0}]$ for the value SchedSelIdx0 of SchedSelIdx that was in use for the previous access unit.
- Otherwise, the HSS continues to operate with the previous values of SchedSelIdx , $\text{BitRate}[\text{SchedSelIdx}]$ and $\text{CpbSize}[\text{SchedSelIdx}]$.

When the HSS selects values of $\text{BitRate}[\text{SchedSelIdx}]$ or $\text{CpbSize}[\text{SchedSelIdx}]$ that differ from those of the previous access unit, the following applies:

- The variable $\text{BitRate}[\text{SchedSelIdx}]$ comes into effect at the initial CPB arrival time of the current access unit.
- The variable $\text{CpbSize}[\text{SchedSelIdx}]$ comes into effect as follows:
 - If the new value of $\text{CpbSize}[\text{SchedSelIdx}]$ is greater than the old CPB size, it comes into effect at the initial CPB arrival time of the current access unit.
 - Otherwise, the new value of $\text{CpbSize}[\text{SchedSelIdx}]$ comes into effect at the CPB removal time of the current access unit.

C.2.3 Timing of decoding unit removal and decoding of decoding unit

The variables $\text{InitCpbRemovalDelay}[\text{SchedSelIdx}]$ and $\text{InitCpbRemovalDelayOffset}[\text{SchedSelIdx}]$ are updated, and the variables CpbDelayOffset and DpbDelayOffset are derived, as follows:

- If one or more of the following conditions are true, CpbDelayOffset is set equal to the value of the buffering period SEI message syntax element cpb_delay_offset , DpbDelayOffset is set equal to the value of the buffering period SEI message syntax element dpb_delay_offset , and $\text{InitCpbRemovalDelay}[\text{SchedSelIdx}]$ and $\text{InitCpbRemovalDelayOffset}[\text{SchedSelIdx}]$ are set equal to the values of the buffering period SEI message syntax elements $\text{nal_initial_alt_cpb_removal_delay}[\text{SchedSelIdx}]$ and $\text{nal_initial_alt_cpb_removal_offset}[\text{SchedSelIdx}]$, respectively, when NalHrdModeFlag is equal to 1, or $\text{vcl_initial_alt_cpb_removal_delay}[\text{SchedSelIdx}]$ and $\text{vcl_initial_alt_cpb_removal_offset}[\text{SchedSelIdx}]$, respectively, when NalHrdModeFlag is equal to 0, where the buffering period SEI message containing the syntax elements is selected as specified in clause C.1:
 - Access unit 0 is a BLA access unit for which the coded picture has nal_unit_type equal to BLA_W_RADL or BLA_N_LP and the value of $\text{irap_cpb_params_present_flag}$ of the buffering period SEI message is equal to 1.
 - Access unit 0 is a BLA access unit for which the coded picture has nal_unit_type equal to BLA_W_LP or is a CRA access unit and the value of $\text{irap_cpb_params_present_flag}$ of the buffering period SEI message is equal to 1 and one or more of the following conditions are true:

- UseAltCpbParamsFlag for access unit 0 is equal to 1.
- DefaultInitCpbParamsFlag is equal to 0.
- Otherwise, InitCpbRemovalDelay[SchedSelIdx] and InitCpbRemovalDelayOffset[SchedSelIdx] are set equal to the values of the buffering period SEI message syntax elements nal_initial_cpb_removal_delay[SchedSelIdx] and nal_initial_cpb_removal_offset[SchedSelIdx], respectively, when NalHrdModeFlag is equal to 1, or vcl_initial_cpb_removal_delay[SchedSelIdx] and vcl_initial_cpb_removal_offset[SchedSelIdx], respectively, when NalHrdModeFlag is equal to 0, where the buffering period SEI message containing the syntax elements is selected as specified in clause C.1, CpbDelayOffset and DpbDelayOffset are both set equal to 0.

The nominal removal time of the access unit n from the CPB is specified as follows:

- If access unit n is the access unit with n equal to 0 (the access unit that initializes the HRD), the nominal removal time of the access unit from the CPB is specified by:

$$\text{AuNominalRemovalTime}[0] = \text{InitCpbRemovalDelay}[\text{SchedSelIdx}] \div 90\,000 \quad (\text{C-9})$$

- Otherwise, the following applies:
 - When access unit n is the first access unit of a buffering period that does not initialize the HRD, the following applies:

The nominal removal time of the access unit n from the CPB is specified by:

$$\begin{aligned}
 & \text{if(!concatenationFlag) } \{ \\
 & \quad \text{baseTime} = \text{AuNominalRemovalTime}[\text{firstPicInPrevBuffPeriod}] \\
 & \quad \text{tmpCpbRemovalDelay} = \text{AuCpbRemovalDelayVal} \\
 & \quad \text{tmpCpbDelayOffset} = \text{CpbDelayOffset} \\
 & \} \text{ else } \{ \\
 & \quad \text{baseTime1} = \text{AuNominalRemovalTime}[\text{prevNonDiscardablePic}] \\
 & \quad \text{tmpCpbRemovalDelay1} = (\text{auCpbRemovalDelayDeltaMinus1} + 1) \\
 & \quad \text{baseTime2} = \text{AuNominalRemovalTime}[n - 1] \\
 & \quad \text{tmpCpbRemovalDelay2} = \text{Ceil}((\text{InitCpbRemovalDelay}[\text{SchedSelIdx}] \div 90\,000 + \\
 & \quad \quad \text{AuFinalArrivalTime}[n - 1] - \text{AuNominalRemovalTime}[n - 1]) \div \text{ClockTick})) \\
 & \quad \text{if(baseTime1 + ClockTick * tmpCpbRemovalDelay1 < } \\
 & \quad \quad \text{baseTime2 + ClockTick * tmpCpbRemovalDelay2) } \{ \\
 & \quad \quad \text{baseTime} = \text{baseTime2} \\
 & \quad \quad \text{tmpCpbRemovalDelay} = \text{tmpCpbRemovalDelay2} \\
 & \quad \} \text{ else } \{ \\
 & \quad \quad \text{baseTime} = \text{baseTime1} \\
 & \quad \quad \text{tmpCpbRemovalDelay} = \text{tmpCpbRemovalDelay1} \\
 & \quad \} \\
 & \quad \text{tmpCpbDelayOffset} = 0 \\
 & \} \\
 & \text{AuNominalRemovalTime}[n] = \text{baseTime} + \\
 & \quad \text{ClockTick} * (\text{tmpCpbRemovalDelay} - \text{tmpCpbDelayOffset})
 \end{aligned} \quad (\text{C-10})$$

where AuNominalRemovalTime[firstPicInPrevBuffPeriod] is the nominal removal time of the first access unit of the previous buffering period, AuNominalRemovalTime[prevNonDiscardablePic] is the nominal removal time of the preceding picture in decoding order with TemporalId equal to 0 that is not a RASL, RADL or SLNR picture, AuCpbRemovalDelayVal is the value of AuCpbRemovalDelayVal derived according to au_cpb_removal_delay_minus1 in the picture timing SEI message, selected as specified in clause C.1, associated with access unit n and concatenationFlag and auCpbRemovalDelayDeltaMinus1 are the values of the syntax elements concatenation_flag and au_cpb_removal_delay_delta_minus1, respectively, in the buffering period SEI message, selected as specified in clause C.1, associated with access unit n.

After the derivation of the nominal CPB removal time and before the derivation of the DPB output time of access unit n, the values of CpbDelayOffset and DpbDelayOffset are updated as follows:

- If one or more of the following conditions are true, CpbDelayOffset is set equal to the value of the buffering period SEI message syntax element cpb_delay_offset, and DpbDelayOffset is set equal to the value of the buffering period SEI message syntax element dpb_delay_offset, where the buffering period SEI message containing the syntax elements is selected as specified in clause C.1:

- Access unit n is a BLA access unit for which the coded picture has `nal_unit_type` equal to `BLA_W_RADL` or `BLA_N_LP` and the value of `irap_cpb_params_present_flag` of the buffering period SEI message is equal to 1.
- Access unit n is a BLA access unit for which the coded picture has `nal_unit_type` equal to `BLA_W_LP` or is a CRA access unit and the value of `irap_cpb_params_present_flag` of the buffering period SEI message is equal to 1 and `UseAltCpbParamsFlag` for access unit n is equal to 1.
- Otherwise, `CpbDelayOffset` and `DpbDelayOffset` are both set equal to 0.
- When access unit n is not the first access unit of a buffering period, the nominal removal time of the access unit n from the CPB is specified by:

$$\text{AuNominalRemovalTime}[n] = \text{AuNominalRemovalTime}[\text{firstPicInCurrBuffPeriod}] + \text{ClockTick} * (\text{AuCpbRemovalDelayVal} - \text{CpbDelayOffset}) \quad (\text{C-11})$$

where $\text{AuNominalRemovalTime}[\text{firstPicInCurrBuffPeriod}]$ is the nominal removal time of the first access unit of the current buffering period and $\text{AuCpbRemovalDelayVal}$ is the value of `AuCpbRemovalDelayVal` derived according to `au_cpb_removal_delay_minus1` in the picture timing SEI message, selected as specified in clause C.1, associated with access unit n .

When `SubPicHrdFlag` is equal to 1, the following applies:

- The variable `duCpbRemovalDelayInc` is derived as follows:
 - If `sub_pic_cpb_params_in_pic_timing_sei_flag` is equal to 0, `duCpbRemovalDelayInc` is set equal to the value of `du_spt_cpb_removal_delay_increment` in the decoding unit information SEI message, selected as specified in clause C.1, associated with decoding unit m .
 - Otherwise, if `du_common_cpb_removal_delay_flag` is equal to 0, `duCpbRemovalDelayInc` is set equal to the value of `du_cpb_removal_delay_increment_minus1[i] + 1` for decoding unit m in the picture timing SEI message, selected as specified in clause C.1, associated with access unit n , where the value of i is 0 for the first `num_nalus_in_du_minus1[0] + 1` consecutive NAL units in the access unit that contains decoding unit m , 1 for the subsequent `num_nalus_in_du_minus1[1] + 1` NAL units in the same access unit, 2 for the subsequent `num_nalus_in_du_minus1[2] + 1` NAL units in the same access unit, etc.
 - Otherwise, `duCpbRemovalDelayInc` is set equal to the value of `du_common_cpb_removal_delay_increment_minus1 + 1` in the picture timing SEI message, selected as specified in clause C.1, associated with access unit n .
- The nominal removal time of decoding unit m from the CPB is specified as follows, where $\text{AuNominalRemovalTime}[n]$ is the nominal removal time of access unit n :
 - If decoding unit m is the last decoding unit in access unit n , the nominal removal time of decoding unit m $\text{DuNominalRemovalTime}[m]$ is set equal to $\text{AuNominalRemovalTime}[n]$.
 - Otherwise (decoding unit m is not the last decoding unit in access unit n), the nominal removal time of decoding unit m $\text{DuNominalRemovalTime}[m]$ is derived as follows:

$$\begin{aligned} &\text{if}(\text{sub_pic_cpb_params_in_pic_timing_sei_flag}) \\ &\quad \text{DuNominalRemovalTime}[m] = \text{DuNominalRemovalTime}[m+1] - \\ &\quad \quad \text{ClockSubTick} * \text{duCpbRemovalDelayInc} \\ &\text{else} \\ &\quad \text{DuNominalRemovalTime}[m] = \text{AuNominalRemovalTime}[n] - \\ &\quad \quad \text{ClockSubTick} * \text{duCpbRemovalDelayInc} \end{aligned} \quad (\text{C-12})$$

If `SubPicHrdFlag` is equal to 0, the removal time of access unit n from the CPB is specified as follows, where $\text{AuFinalArrivalTime}[n]$ and $\text{AuNominalRemovalTime}[n]$ are the final CPB arrival time and nominal CPB removal time, respectively, of access unit n :

$$\begin{aligned} &\text{if}(\text{!low_delay_hrd_flag}[\text{HighestTid}] \parallel \text{AuNominalRemovalTime}[n] \geq \text{AuFinalArrivalTime}[n]) \\ &\quad \text{AuCpbRemovalTime}[n] = \text{AuNominalRemovalTime}[n] \\ &\text{else} \\ &\quad \text{AuCpbRemovalTime}[n] = \text{AuNominalRemovalTime}[n] + \text{ClockTick} * \\ &\quad \quad \text{Ceil}((\text{AuFinalArrivalTime}[n] - \text{AuNominalRemovalTime}[n]) \div \text{ClockTick}) \end{aligned} \quad (\text{C-13})$$

NOTE 1 – When `low_delay_hrd_flag[HighestTid]` is equal to 1 and `AuNominalRemovalTime[n]` is less than `AuFinalArrivalTime[n]`, the size of access unit `n` is so large that it prevents removal at the nominal removal time.

Otherwise (`SubPicHrdFlag` is equal to 1), the removal time of decoding unit `m` from the CPB is specified as follows:

```

if( !low_delay_hrd_flag[ HighestTid ] || DuNominalRemovalTime[ m ] >= DuFinalArrivalTime[ m ]
)
    DuCpbRemovalTime[ m ] = DuNominalRemovalTime[ m ]
else
    DuCpbRemovalTime[ m ] = DuFinalArrivalTime[ m ]

```

(C-14)

NOTE 2 – When `low_delay_hrd_flag[HighestTid]` is equal to 1 and `DuNominalRemovalTime[m]` is less than `DuFinalArrivalTime[m]`, the size of decoding unit `m` is so large that it prevents removal at the nominal removal time.

If `SubPicHrdFlag` is equal to 0, at the CPB removal time of access unit `n`, the access unit is instantaneously decoded.

Otherwise (`SubPicHrdFlag` is equal to 1), at the CPB removal time of decoding unit `m`, the decoding unit is instantaneously decoded, and when decoding unit `m` is the last decoding unit of access unit `n`, the following applies:

- Picture `n` is considered as decoded.
- The final CPB arrival time of access unit `n`, i.e., `AuFinalArrivalTime[n]`, is set equal to the final CPB arrival time of the last decoding unit in access unit `n`, i.e., `DuFinalArrivalTime[m]`.
- The nominal CPB removal time of access unit `n`, i.e., `AuNominalRemovalTime[n]`, is set equal to the nominal CPB removal time of the last decoding unit in access unit `n`, i.e., `DuNominalRemovalTime[m]`.
- The CPB removal time of access unit `n`, i.e., `AuCpbRemovalTime[m]`, is set equal to the CPB removal time of the last decoding unit in access unit `n`, i.e., `DuCpbRemovalTime[m]`.

C.3 Operation of the decoded picture buffer

C.3.1 General

The specifications in this clause apply independently to each set of decoded picture buffer (DPB) parameters selected as specified in clause C.1.

The decoded picture buffer contains picture storage buffers. Each of the picture storage buffers may contain a decoded picture that is marked as "used for reference" or is held for future output. The processes specified in clauses C.3.2, C.3.3, C.3.4 and C.3.5 are sequentially applied as specified below.

C.3.2 Removal of pictures from the DPB before decoding of the current picture

The removal of pictures from the DPB before decoding of the current picture (but after parsing the slice header of the first slice of the current picture) happens instantaneously at the CPB removal time of the first decoding unit of access unit `n` (containing the current picture) and proceeds as follows:

- The decoding process for RPS as specified in clause 8.3.2 is invoked.
- When the current picture is an IRAP picture with `NoRasOutputFlag` equal to 1 that is not picture 0, the following ordered steps are applied:
 1. The variable `NoOutputOfPriorPicsFlag` is derived for the decoder under test as follows:
 - If the current picture is a CRA picture, `NoOutputOfPriorPicsFlag` is set equal to 1 (regardless of the value of `no_output_of_prior_pics_flag`).
 - Otherwise, if the value of `pic_width_in_luma_samples`, `pic_height_in_luma_samples`, `chroma_format_idc`, `separate_colour_plane_flag`, `bit_depth_luma_minus8`, `bit_depth_chroma_minus8` or `sps_max_dec_pic_buffering_minus1[HighestTid]` derived from the active SPS is different from the value of `pic_width_in_luma_samples`, `pic_height_in_luma_samples`, `chroma_format_idc`, `separate_colour_plane_flag`, `bit_depth_luma_minus8`, `bit_depth_chroma_minus8` or `sps_max_dec_pic_buffering_minus1[HighestTid]`, respectively, derived from the SPS active for the preceding picture, `NoOutputOfPriorPicsFlag` may (but should not) be set to 1 by the decoder under test, regardless of the value of `no_output_of_prior_pics_flag`.

NOTE – Although setting `NoOutputOfPriorPicsFlag` equal to `no_output_of_prior_pics_flag` is preferred under these conditions, the decoder under test is allowed to set `NoOutputOfPriorPicsFlag` to 1 in this case.
 - Otherwise, `NoOutputOfPriorPicsFlag` is set equal to `no_output_of_prior_pics_flag`.

2. The value of NoOutputOfPriorPicsFlag derived for the decoder under test is applied for the HRD, such that when the value of NoOutputOfPriorPicsFlag is equal to 1, all picture storage buffers in the DPB are emptied without output of the pictures they contain, and the DPB fullness is set equal to 0.
- When both of the following conditions are true for any pictures k in the DPB, all such pictures k in the DPB are removed from the DPB:
 - picture k is marked as "unused for reference".
 - picture k has PicOutputFlag equal to 0 or its DPB output time is less than or equal to the CPB removal time of the first decoding unit (denoted as decoding unit m) of the current picture n; i.e., DpbOutputTime[k] is less than or equal to DuCpbRemovalTime[m].
 - For each picture that is removed from the DPB, the DPB fullness is decremented by one.

C.3.3 Picture output

The processes specified in this clause happen instantaneously at the CPB removal time of access unit n, AuCpbRemovalTime[n].

When picture n has PicOutputFlag equal to 1, its DPB output time DpbOutputTime[n] is derived as follows, where the variable firstPicInBufferingPeriodFlag is equal to 1 if access unit n is the first access unit of a buffering period and 0 otherwise:

```

if( !SubPicHrdFlag ) {
    DpbOutputTime[ n ] = AuCpbRemovalTime[ n ] + ClockTick * picDpbOutputDelay      (C-15)
    if( firstPicInBufferingPeriodFlag )
        DpbOutputTime[ n ] -= ClockTick * DpbDelayOffset
    } else
        DpbOutputTime[ n ] = AuCpbRemovalTime[ n ] + ClockSubTick * picSptDpbOutputDuDelay

```

where picDpbOutputDelay is the value of pic_dpb_output_delay in the picture timing SEI message associated with access unit n, and picSptDpbOutputDuDelay is the value of pic_spt_dpb_output_du_delay, when present, in the decoding unit information SEI messages associated with access unit n, or the value of pic_dpb_output_du_delay in the picture timing SEI message associated with access unit n when there is no decoding unit information SEI message associated with access unit n or no decoding unit information SEI message associated with access unit n has pic_spt_dpb_output_du_delay present.

NOTE – When the syntax element pic_spt_dpb_output_du_delay is not present in any decoding unit information SEI message associated with access unit n, the value is inferred to be equal to pic_dpb_output_du_delay in the picture timing SEI message associated with access unit n.

The output of the current picture is specified as follows:

- If PicOutputFlag is equal to 1 and DpbOutputTime[n] is equal to AuCpbRemovalTime[n], the current picture is output.
- Otherwise, if PicOutputFlag is equal to 0, the current picture is not output, but will be stored in the DPB as specified in clause C.3.4.
- Otherwise (PicOutputFlag is equal to 1 and DpbOutputTime[n] is greater than AuCpbRemovalTime[n]), the current picture is output later and will be stored in the DPB (as specified in clause C.3.4) and is output at time DpbOutputTime[n] unless indicated not to be output by NoOutputOfPriorPicsFlag equal to 1.

When output, the picture is cropped, using the conformance cropping window specified in the active SPS for the picture.

When picture n is a picture that is output and is not the last picture of the bitstream that is output, the value of the variable DpbOutputInterval[n] is derived as follows:

$$\text{DpbOutputInterval}[n] = \text{DpbOutputTime}[\text{nextPicInOutputOrder}] - \text{DpbOutputTime}[n] \quad (\text{C-16})$$

where nextPicInOutputOrder is the picture that follows picture n in output order and has PicOutputFlag equal to 1.

C.3.4 Current decoded picture marking and storage

The current decoded picture after the invocation of the in-loop filter process as specified in clause 8.7 is stored in the DPB in an empty picture storage buffer, the DPB fullness is incremented by one. When TwoVersionsOfCurrDecPicFlag is equal to 0 and pps_curr_pic_ref_enabled_flag is equal to 1, this picture is marked as "used for long-term reference". After all the slices of the current picture have been decoded, this picture is marked as "used for short-term reference".

When TwoVersionsOfCurrDecPicFlag is equal to 1, the current decoded picture before the invocation of the in-loop filter process as specified in clause 8.7 is stored in the DPB in an empty picture storage buffer, the DPB fullness is incremented by one, and this picture is marked as "used for long-term reference".

NOTE – Unless more memory than required by the level limit is available for storage of decoded pictures, decoders should start storing decoded parts of the current picture into the DPB when the first slice segment is decoded and continue storing more decoded samples as the decoding process proceeds.

C.3.5 Removal of pictures from the DPB after decoding of the current picture

When TwoVersionsOfCurrDecPicFlag is equal to 1, immediately after decoding of the current picture, at the CPB removal time of the last decoding unit of access unit n (containing the current picture), the current decoded picture before the invocation of the in-loop filter process as specified in clause 8.7 is removed from the DPB, and the DPB fullness is decremented by one.

C.4 Bitstream conformance

A bitstream of coded data conforming to this Specification shall fulfil all requirements specified in this clause.

The bitstream shall be constructed according to the syntax, semantics and constraints specified in this Specification outside of this annex.

The first coded picture in a bitstream shall be an IRAP picture, i.e., an IDR picture, a CRA picture or a BLA picture.

The bitstream is tested by the HRD for conformance as specified in clause C.1.

For each current picture, let the variables maxPicOrderCnt and minPicOrderCnt be set equal to the maximum and the minimum, respectively, of the PicOrderCntVal values of the following pictures:

- The current picture.
- The previous picture in decoding order that has TemporalId equal to 0 and that is not a RASL, RADL, or SLNR picture.
- The short-term reference pictures in the RPS of the current picture.
- All pictures n that have PicOutputFlag equal to 1, AuCpbRemovalTime[n] less than AuCpbRemovalTime[currPic] and DpbOutputTime[n] greater than or equal to AuCpbRemovalTime[currPic], where currPic is the current picture.

All of the following conditions shall be fulfilled for each of the bitstream conformance tests:

1. For each access unit n, with n greater than 0, associated with a buffering period SEI message, let the variable deltaTime90k[n] be specified as follows:

$$\text{deltaTime90k}[n] = 90\,000 * (\text{AuNominalRemovalTime}[n] - \text{AuFinalArrivalTime}[n-1])$$

(C-17)

The value of InitCpbRemovalDelay[SchedSelIdx] is constrained as follows:

- If cbr_flag[SchedSelIdx] is equal to 0, the following condition shall be true:

$$\text{InitCpbRemovalDelay}[\text{SchedSelIdx}] \leq \text{Ceil}(\text{deltaTime90k}[n])$$

(C-18)

- Otherwise (cbr_flag[SchedSelIdx] is equal to 1), the following condition shall be true:

$$\text{Floor}(\text{deltaTime90k}[n]) \leq \text{InitCpbRemovalDelay}[\text{SchedSelIdx}] \leq \text{Ceil}(\text{deltaTime90k}[n])$$

(C-19)

NOTE 1 – The exact number of bits in the CPB at the removal time of each picture may depend on which buffering period SEI message is selected to initialize the HRD. Encoders must take this into account to ensure that all specified constraints must be obeyed regardless of which buffering period SEI message is selected to initialize the HRD, as the HRD may be initialized at any one of the buffering period SEI messages.

2. A CPB overflow is specified as the condition in which the total number of bits in the CPB is greater than the CPB size. The CPB shall never overflow.
3. When low_delay_hrd_flag[HighestTid] is equal to 0, the CPB shall never underflow. A CPB underflow is specified as follows:

- If SubHrdFlag is equal to 0, a CPB underflow is specified as the condition in which the nominal CPB removal time of access unit n $AuNominalRemovalTime[n]$ is less than the final CPB arrival time of access unit n $AuFinalArrivalTime[n]$ for at least one value of n .
 - Otherwise (SubPicHrdFlag is equal to 1), a CPB underflow is specified as the condition in which the nominal CPB removal time of decoding unit m $DuNominalRemovalTime[m]$ is less than the final CPB arrival time of decoding unit m $DuFinalArrivalTime[m]$ for at least one value of m .
4. When SubPicHrdFlag is equal to 1, $low_delay_hrd_flag[HighestTid]$ is equal to 1 and the nominal removal time of a decoding unit m of access unit n is less than the final CPB arrival time of decoding unit m (i.e., $DuNominalRemovalTime[m] < DuFinalArrivalTime[m]$), the nominal removal time of access unit n shall be less than the final CPB arrival time of access unit n (i.e., $AuNominalRemovalTime[n] < AuFinalArrivalTime[n]$).
 5. The nominal removal times of pictures from the CPB (starting from the second picture in decoding order) shall satisfy the constraints on $AuNominalRemovalTime[n]$ and $AuCpbRemovalTime[n]$ expressed in clauses A.4.1 through A.4.2.
 6. For each current picture, after invocation of the process for removal of pictures from the DPB as specified in clause C.3.2, the number of decoded pictures in the DPB, including all pictures n that are marked as "used for reference", or that have $PicOutputFlag$ equal to 1 and $AuCpbRemovalTime[n]$ less than $AuCpbRemovalTime[currPic]$, where $currPic$ is the current picture, shall be less than or equal to $sps_max_dec_pic_buffering_minus1[HighestTid]$.
 7. All reference pictures shall be present in the DPB when needed for prediction. Each picture that has $PicOutputFlag$ equal to 1 shall be present in the DPB at its DPB output time unless it is removed from the DPB before its output time by one of the processes specified in clause C.3.
 8. For each current picture that is not an IRAP picture with $NoRaslOutputFlag$ equal to 1, the value of $maxPicOrderCnt - minPicOrderCnt$ shall be less than $MaxPicOrderCntLsb / 2$.
 9. The value of $DpbOutputInterval[n]$ as given by Equation C-16, which is the difference between the output time of a picture and that of the first picture following it in output order and having $PicOutputFlag$ equal to 1, shall satisfy the constraint expressed in clause A.4.1 for the profile, tier and level specified in the bitstream using the decoding process specified in clauses 2 through 10.
 10. For each current picture, when $sub_pic_cpb_params_in_pic_timing_sei_flag$ is equal to 1, let $tmpCpbRemovalDelaySum$ be derived as follows:

$$\begin{aligned}
 &tmpCpbRemovalDelaySum = 0 \\
 &\text{for}(i = 0; i < num_decoding_units_minus1; i++) \\
 &\quad tmpCpbRemovalDelaySum += du_cpb_removal_delay_increment_minus1[i] + 1
 \end{aligned} \tag{C-20}$$

The value of $ClockSubTick * tmpCpbRemovalDelaySum$ shall be equal to the difference between the nominal CPB removal time of the current access unit and the nominal CPB removal time of the first decoding unit in the current access unit in decoding order.

11. For any two pictures m and n in the same CVS, when $DpbOutputTime[m]$ is greater than $DpbOutputTime[n]$, the $PicOrderCntVal$ of picture m shall be greater than the $PicOrderCntVal$ of picture n .

NOTE 2 – All pictures of an earlier CVS in decoding order that are output are output before any pictures of a later CVS in decoding order. Within any particular CVS, the pictures that are output are output in increasing $PicOrderCntVal$ order.

C.5 Decoder conformance

C.5.1 General

A decoder conforming to this Specification shall fulfil all requirements specified in this clause.

A decoder claiming conformance to a specific profile, tier and level shall be able to successfully decode all bitstreams that conform to the bitstream conformance requirements specified in clause C.4, in the manner specified in Annex A, provided that all VPSs, SPSs and PPSs referred to in the VCL NAL units and appropriate buffering period, picture timing and decoding unit information SEI messages are conveyed to the decoder, in a timely manner, either in the bitstream (by non-VCL NAL units), or by external means not specified in this Specification.

When a bitstream contains syntax elements that have values that are specified as reserved and it is specified that decoders shall ignore values of the syntax elements or NAL units containing the syntax elements having the reserved values, and

the bitstream is otherwise conforming to this Specification, a conforming decoder shall decode the bitstream in the same manner as it would decode a conforming bitstream and shall ignore the syntax elements or the NAL units containing the syntax elements having the reserved values as specified.

There are two types of conformance that can be claimed by a decoder: output timing conformance and output order conformance.

To check conformance of a decoder, test bitstreams conforming to the claimed profile, tier and level, as specified in clause C.4 are delivered by a hypothetical stream scheduler (HSS) both to the HRD and to the decoder under test (DUT). All cropped decoded pictures output by the HRD shall also be output by the DUT, each cropped decoded picture output by the DUT shall be a picture with PicOutputFlag equal to 1, and, for each such cropped decoded picture output by the DUT, the values of all samples that are output shall be equal to the values of the samples produced by the specified decoding process.

For output timing decoder conformance, the HSS operates as described above, with delivery schedules selected only from the subset of values of SchedSelIdx for which the bit rate and CPB size are restricted as specified in Annex A for the specified profile, tier and level or with "interpolated" delivery schedules as specified below for which the bit rate and CPB size are restricted as specified in Annex A. The same delivery schedule is used for both the HRD and the DUT.

When the HRD parameters and the buffering period SEI messages are present with cpb_cnt_minus1[HighestTid] greater than 0, the decoder shall be capable of decoding the bitstream as delivered from the HSS operating using an "interpolated" delivery schedule specified as having peak bit rate r , CPB size $c(r)$ and initial CPB removal delay $(f(r) \div r)$ as follows:

$$\alpha = (r - \text{BitRate}[\text{SchedSelIdx} - 1]) \div (\text{BitRate}[\text{SchedSelIdx}] - \text{BitRate}[\text{SchedSelIdx} - 1]), \quad (\text{C-21})$$

$$c(r) = \alpha * \text{CpbSize}[\text{SchedSelIdx}] + (1 - \alpha) * \text{CpbSize}[\text{SchedSelIdx} - 1], \quad (\text{C-22})$$

$$f(r) = \alpha * \text{InitCpbRemovalDelay}[\text{SchedSelIdx}] * \text{BitRate}[\text{SchedSelIdx}] + (1 - \alpha) * \text{InitCpbRemovalDelay}[\text{SchedSelIdx} - 1] * \text{BitRate}[\text{SchedSelIdx} - 1] \quad (\text{C-23})$$

for any SchedSelIdx > 0 and r such that $\text{BitRate}[\text{SchedSelIdx} - 1] \leq r \leq \text{BitRate}[\text{SchedSelIdx}]$ such that r and $c(r)$ are within the limits as specified in Annex A for the maximum bit rate and buffer size for the specified profile, tier and level.

NOTE 1 – InitCpbRemovalDelay[SchedSelIdx] can be different from one buffering period to another and have to be re-calculated.

For output timing decoder conformance, an HRD as described above is used and the timing (relative to the delivery time of the first bit) of picture output is the same for both the HRD and the DUT up to a fixed delay.

For output order decoder conformance, the following applies:

- The HSS delivers the bitstream BitstreamToDecode to the DUT "by demand" from the DUT, meaning that the HSS delivers bits (in decoding order) only when the DUT requires more bits to proceed with its processing.
NOTE 2 – This means that for this test, the coded picture buffer of the DUT could be as small as the size of the largest decoding unit.
- A modified HRD as described below is used, and the HSS delivers the bitstream to the HRD by one of the schedules specified in the bitstream BitstreamToDecode such that the bit rate and CPB size are restricted as specified in Annex A. The order of pictures output shall be the same for both the HRD and the DUT.
- The HRD CPB size is given by CpbSize[SchedSelIdx] as specified in clause E.3.3, where SchedSelIdx and the HRD parameters are selected as specified in clause C.1. The DPB size is given by $\text{sps_max_dec_pic_buffering_minus1}[\text{HighestTid}] + 1$. Removal time from the CPB for the HRD is the final bit arrival time and decoding is immediate. The operation of the DPB of this HRD is as described in clauses C.5.2 through C.5.2.3.

C.5.2 Operation of the output order DPB

C.5.2.1 General

The decoded picture buffer contains picture storage buffers. Each of the picture storage buffers contains a decoded picture that is marked as "used for reference" or is held for future output. The process for output and removal of pictures from the DPB before decoding of the current picture as specified in clause C.5.2.2 is invoked, the invocation of the process for current decoded picture marking and storage as specified in clause C.3.4, further followed by the invocation of the process for removal of pictures from the DPB after decoding of the current picture as specified in clause C.3.5, and finally followed by the invocation of the process for additional bumping as specified in clause C.5.2.3. The "bumping" process is specified in clause C.5.2.4 and is invoked as specified in clauses C.5.2.2 and C.5.2.3.

C.5.2.2 Output and removal of pictures from the DPB

The output and removal of pictures from the DPB before the decoding of the current picture (but after parsing the slice header of the first slice of the current picture) happens instantaneously when the first decoding unit of the access unit containing the current picture is removed from the CPB and proceeds as follows:

- The decoding process for RPS as specified in clause 8.3.2 is invoked.
- If the current picture is an IRAP picture with NoRaslOutputFlag equal to 1 that is not picture 0, the following ordered steps are applied:
 1. The variable NoOutputOfPriorPicsFlag is derived for the decoder under test as follows:
 - If the current picture is a CRA picture, NoOutputOfPriorPicsFlag is set equal to 1 (regardless of the value of no_output_of_prior_pics_flag).
 - Otherwise, if the value of pic_width_in_luma_samples, pic_height_in_luma_samples, chroma_format_idc, separate_colour_plane_flag, bit_depth_luma_minus8, bit_depth_chroma_minus8 or sps_max_dec_pic_buffering_minus1[HighestTid] derived from the active SPS is different from the value of pic_width_in_luma_samples, pic_height_in_luma_samples, chroma_format_idc, separate_colour_plane_flag, bit_depth_luma_minus8, bit_depth_chroma_minus8 or sps_max_dec_pic_buffering_minus1[HighestTid], respectively, derived from the SPS active for the preceding picture, NoOutputOfPriorPicsFlag may (but should not) be set to 1 by the decoder under test, regardless of the value of no_output_of_prior_pics_flag.

NOTE – Although setting NoOutputOfPriorPicsFlag equal to no_output_of_prior_pics_flag is preferred under these conditions, the decoder under test is allowed to set NoOutputOfPriorPicsFlag to 1 in this case.
 - Otherwise, NoOutputOfPriorPicsFlag is set equal to no_output_of_prior_pics_flag.
 2. The value of NoOutputOfPriorPicsFlag derived for the decoder under test is applied for the HRD as follows:
 - If NoOutputOfPriorPicsFlag is equal to 1, all picture storage buffers in the DPB are emptied without output of the pictures they contain and the DPB fullness is set equal to 0.
 - Otherwise (NoOutputOfPriorPicsFlag is equal to 0), all picture storage buffers containing a picture that is marked as "not needed for output" and "unused for reference" are emptied (without output) and all non-empty picture storage buffers in the DPB are emptied by repeatedly invoking the "bumping" process specified in clause C.5.2.4 and the DPB fullness is set equal to 0.
- Otherwise (the current picture is not an IRAP picture with NoRaslOutputFlag equal to 1), all picture storage buffers containing a picture which are marked as "not needed for output" and "unused for reference" are emptied (without output). For each picture storage buffer that is emptied, the DPB fullness is decremented by one. When one or more of the following conditions are true, the "bumping" process specified in clause C.5.2.4 is invoked repeatedly while further decrementing the DPB fullness by one for each additional picture storage buffer that is emptied, until none of the following conditions are true:
 - The number of pictures in the DPB that are marked as "needed for output" is greater than sps_max_num_reorder_pics[HighestTid].
 - sps_max_latency_increase_plus1[HighestTid] is not equal to 0 and there is at least one picture in the DPB that is marked as "needed for output" for which the associated variable PicLatencyCount is greater than or equal to SpsMaxLatencyPictures[HighestTid].
 - The number of pictures in the DPB is greater than or equal to sps_max_dec_pic_buffering_minus1[HighestTid] + 1 – TwoVersionsOfCurrDecPicFlag.

C.5.2.3 Additional bumping

The processes specified in this clause happen instantaneously when the last decoding unit of access unit n containing the current picture is removed from the CPB.

When the current picture has PicOutputFlag equal to 1, for each picture in the DPB that is marked as "needed for output" and follows the current picture in output order, the associated variable PicLatencyCount is set equal to PicLatencyCount + 1.

The following applies:

- If the current decoded picture has PicOutputFlag equal to 1, it is marked as "needed for output" and its associated variable PicLatencyCount is set equal to 0.
- Otherwise (the current decoded picture has PicOutputFlag equal to 0), it is marked as "not needed for output".

When one or more of the following conditions are true, the "bumping" process specified in clause C.5.2.4 is invoked repeatedly until none of the following conditions are true:

- The number of pictures in the DPB that are marked as "needed for output" is greater than `sps_max_num_reorder_pics[HighestTid]`.
- `sps_max_latency_increase_plus1[HighestTid]` is not equal to 0 and there is at least one picture in the DPB that is marked as "needed for output" for which the associated variable `PicLatencyCount` that is greater than or equal to `SpsMaxLatencyPictures[HighestTid]`.

C.5.2.4 "Bumping" process

The "bumping" process consists of the following ordered steps:

1. The picture that is first for output is selected as the one having the smallest value of `PicOrderCntVal` of all pictures in the DPB marked as "needed for output".
2. The picture is cropped, using the conformance cropping window specified in the active SPS for the picture, the cropped picture is output, and the picture is marked as "not needed for output".
3. When the picture storage buffer that included the picture that was cropped and output contains a picture marked as "unused for reference", the picture storage buffer is emptied.

NOTE – For any two pictures `picA` and `picB` that belong to the same CVS and are output by the "bumping process", when `picA` is output earlier than `picB`, the value of `PicOrderCntVal` of `picA` is less than the value of `PicOrderCntVal` of `picB`.

Annex D

Supplemental enhancement information

(This annex forms an integral part of this Recommendation | International Standard.)

D.1 General

This annex specifies syntax and semantics for SEI message payloads.

SEI messages assist in processes related to decoding, display or other purposes. However, SEI messages are not required for constructing the luma or chroma samples by the decoding process. Conforming decoders are not required to process this information for output order conformance to this Specification (see Annex C and clause F.13 for the specification of conformance). Some SEI message information is required to check bitstream conformance and for output timing decoder conformance.

In clause C.5.2 and in clause F.13 including its subclauses, specification for presence of SEI messages are also satisfied when those messages (or some subset of them) are conveyed to decoders (or to the HRD) by other means not specified in this Specification. When present in the bitstream, SEI messages shall obey the syntax and semantics specified in clause 7.3.5 and this annex. When the content of an SEI message is conveyed for the application by some means other than presence within the bitstream, the representation of the content of the SEI message is not required to use the same syntax specified in this annex. For the purpose of counting bits, only the appropriate bits that are actually present in the bitstream are counted.
